A Michigan company has closed a contract with the German government, for the following metal: 500 tons of cakes, bars, and ingots, to be delivered to warehouse in New York each month for five months, commencing in March, but not to be delivered until after the War, at 28c. per lb. This shows that Germany considers that the price of copper will keep up after the War.—The Mass company has sold copper for April delivery at 28.75 cents.

The 1915 output of the United Verde was 45,127,832 lb. copper, 902,880 oz. silver, and 28,221 oz. gold, against 32,449,116 lb., 646,285 oz., and 21,393 oz. respectively. Cash on January 1 amounted to $1,163,044.

LEAD

Lead is quoted in cents per pound, New York delivery.

A record price was paid for 80% lead product at Joplin last week, namely, $89 per ton.

On March 20 the St. Joseph Lead Co. will pay a 2½% dividend, an increase on last quarter of 1%.——On March 4 the Bunker Hill & Sullivan pays two dividends, totaling $163,500; the amount to date is $17,100,000.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. Prices, in dollars per flask of 75 pounds:

Tin is firm at 47 to 47.75 cents.

Eastern Metal Market

New York, February 25

With the situation in producers' hands the copper market is as strong as ever, although there has been a lull in buying in the past few days. The London quotation for electrolytic is a trifle lower, and there is an intimation that the British government may endeavor to force the price down. Its minimum of £100, fixed a few weeks ago, has been exceeded by £36. A strike among brass-mill workers at Ansonia, Conn., has exerted a slight depressing effect on the market. Zinc is less active, and a trifle easier. Sheet zinc has been advanced to 25c. per lb. for carloads. Lead is strong, and further advances are expected in view of the fact that export sales are made at premiums over the quotations of the leading interests. Tin shows a tendency to advance, due to the lack of sellers. It is becoming more difficult to obtain licenses to ship from England. Antimony is as scarce as ever, and higher. Aluminum continues to advance.

The larger steel-mills have advanced their quotations for plates, shapes and bars $5 per ton, and now ask 2.75c. for plates, 2.50c. for bars, and 2.25c. for shapes. All of these went begging a year ago at 1.10c. Eastern Pennsylvania plate-makers are asking 3 to 3.25c. Most deliveries contracted for today are to be made at the convenience of the mills. Pig-iron is active. The railroad-freight embargoes are alternately raised and lowered, and continue to hamper business. Practically all grades of pig-iron are about $5 per ton higher than they were a year ago. Open-hearth re-rolling billets are quoted at $35, Pittsburg, per ton, against $19.50 a year ago.

COPPER

In a general way the situation in copper is unchanged. Its strength is unimpaired, but there is a lull in demand. Electrolytic at London was 10s. lower at £136, February 24. A strike of workers in the Ansonia mills of the American Brass Co. is a disquieting influence, although it is felt that the trouble will not be of long duration. This strike, and the slightly lower market at London, has unquestionably had the effect of causing consumers to hold-off in buying. The producing interests appear to have the situation well in hand, and no pronounced reaction in prices is looked for just yet, although ultimately it must come. June and July deliveries of electrolytic continue to command 27.25c. For later than July 26.50c. can be done. Lake is nominally quoted about ¼c. over electrolytic. Prompt deliveries of electrolytic range from 28.50 to 29c., 30 days, delivered. There is a hint that the British government may take steps to curb the high prices which have prevailed at London, though just how this can be accomplished is not clear. New inquiries for shrapnel-fuses are appearing in this market, and Canadian interests are planning to undertake more fuse work, all of which will mean the consumption of more copper and brass. Canadian interests are looking for several hundred tons of copper tubes for shell-bands, but it is questionable where they will find the material. Exports of copper up to and including February 24 totaled 17,548 tons.

ZINC

Following the period of activity which was referred to a week ago, the market has been quieter, but prices are well maintained at around 21.25c., New York, and 21c. St. Louis for prime Western. Early deliveries continue difficult to secure. The Ansonia strike has probably had more effect on zinc than on copper, in the way of making consumers lessen their buying. March commands about 20c., April about 19.25c., and May, June, and July about 18c. The London market continues strong, the quotation advancing £1 to £106, February 24. The metal is at too high a level to encourage buying on the part of the galvanizing trade, a condition which is reflected by the case of a manufacturer of galvanized shingles, who discontinued to make his regular product, and turned his attention to painted metal shingles. Painted roofing is finding a much wider use than formerly. Exports of this month up to and including February 24 totaled 2375 tons.

The base price of sheet-zinc in carload lots is 25c., f.o.b. mill, 8% off for cash.

LEAD

At the present time, independent producers, all of whom are well sold up, are asking about 2½ points over the quotation of the A. S. & R. Co., and the trade daily expects an advance to be announced by the large interest. In the past week the A. S. & R. quotation has been 6.30c., New York, and 6.22½c., St. Louis. The advance of only $1 per ton, February 16 was a great surprise to the trade, as it was thought that a more substantial advance was warranted. Foreign business has been taken at a premium of $4 per ton over the domestic market level. February exports, up to and including the 24th, totaled 4309 tons.

TIN

Advices that it is becoming more difficult to secure licenses to ship tin from England has caused brokers here to hold more tightly to their metal in order to preserve their ability to meet their commitments, and the result has been fewer offerings of prompt metal and consequent higher prices. The quotation for spot on the 24th was 43.25c., with consumers offering 43c. At the same time, arrivals have been fair, totaling up to the 24th, 3752 tons, while there was afloat on that day 5916 tons, most of which is due to arrive in March, with some in April. The United States government has bought several hundred tons for its own use, which will be brought from the Far East on its own colliers and vessels which carry supplies to the Philippines. The purchase was made through London.

ANTIMONY

Recent large arrivals did not find their way to the market, and prices are still stronger. For spot metal 41c. duty paid has been done. March is quoted at 34c. in bond, and April at 33½c. Needle antimony is offered at 24.50c., but there is little doing. Canadian munition-makers have been large buyers.

ALUMINUM

Spot aluminum is exceedingly scarce, and the quotation for No. 1 Virgin, 98 to 99% pure, cannot be had at much less than 60 cents.

MANGANESE

The supply of standard 80% ferro-manganese in this country is running low, and many of the steel-mills and steel-foundries are facing a serious situation. Some of the latter have only three months' supply. The furnace operators are turning their attention to spiegeleisen, containing from 16 to 20% manganese, but its use means difficulties of a technical nature in furnace operation. Spot ferro-manganese is quoted at $250 per ton, and forward deliveries from England, and these are limited in quantity, at $150. It is not thought that all of the forward material which has been contracted for will ever reach this country. The only foreign ore coming here is from Brazil, and the shipping facilities are most restricted. Optimistic people say there must be rich manganese ore in this country, and there would seem to be a fortune waiting for the person who finds it. Ferro-manganese is made in the blast-furnace, and on a smaller scale in the electric-furnace.

MINING DECISIONS

Oil Rentals Not Enforceable at Law

In a lease providing for specified rentals upon failure of the lessee to drill wells within a given time, in the absence of an absolute covenant to pay the rentals, the lessor's only remedy for non-payment is to forfeit the lessee's rights, and he cannot recover judgment for the rentals in an action at law.

Kansas City Oil & Development Co. *v.* Irick (Indiana), 110 Northeastern, 566. December 7, 1915.

Note. Quite the opposite is the rule where there is an absolute covenant on the part of the lessee to pay the rentals in lieu of operating. In such event the lessor may, at his option, sue and recover delinquent rentals.

Hefner *v.* Light Fuel & Power Co. (West Virginia), 87 Southeastern, 206. November 23, 1915.

New Regulations Covering Agricultural Entries of Phosphate, Oil, and Other Mineral Lands.

Mining and oil men will be interested in the terms under which agricultural entries may be made in accordance with the provisions of the Act of July 17, 1914, upon lands withdrawn from entry by the United States because of their phosphate, nitrate, potash, oil, gas, or asphaltic-mineral deposits. The new Regulations of the Interior Department covering this subject set forth the procedure to be followed by such applicants, and note that no protection is afforded by the act to the surface owner against such disturbance of his possession as Congress may in the future authorize to grantees of the mineral rights reserved by the Government. Further provision is made for the granting of patents without mineral reservations where the claimant can prove that lands withdrawn as mineral are in fact non-mineral.

Regulations, March 20, 1915, 44 Land Decisions, 32.

Mineral Lease—Cancellation Granted—Diligence

A lease of oil, gas, and mineral rights was made upon a one dollar consideration, and an agreement by the lessees to pay one-eighth of the net proceeds from the sale of anything of value found, and to begin to drill one or more wells within two years under penalty of forfeiture. The lessees drilled a well to a vein of coal and then ceased operations, waiting, as they claimed, for the value of the coal in its natural state to rise, which would be to the mutual advantage of the lessor and lessee. The lessor neither agreed nor objected to the delay, simply waited for several years and then brought suit to cancel the lease. Held, cancellation justified for lack of diligence in development.

Soaper *v.* King (Kentucky), 180 Southwestern, 46. November 30, 1915.

Mining Company—Grounds for Receivership

The directors of the Goldfield Merger Mines Co. had met but four times in four years and did not call a stockholders' meeting for more than three years, during which time the company expended $250,000, which was practically all of its available funds, and also sold property for $50,000 which a short time afterward was worth $500,000. All of such business was transacted without authority from the directors by officers who were also officers or employees of other mining companies having the same majority stockholders. The work alone was not calculated to, and did not benefit the Merger Mines, but did benefit the other companies. Held, that such facts entitled the minority stockholders to the appointment of a receiver.

Ames *v.* Goldfield Merger Mines Co (Washington), 227 Federal, 292. May 6, 1915.

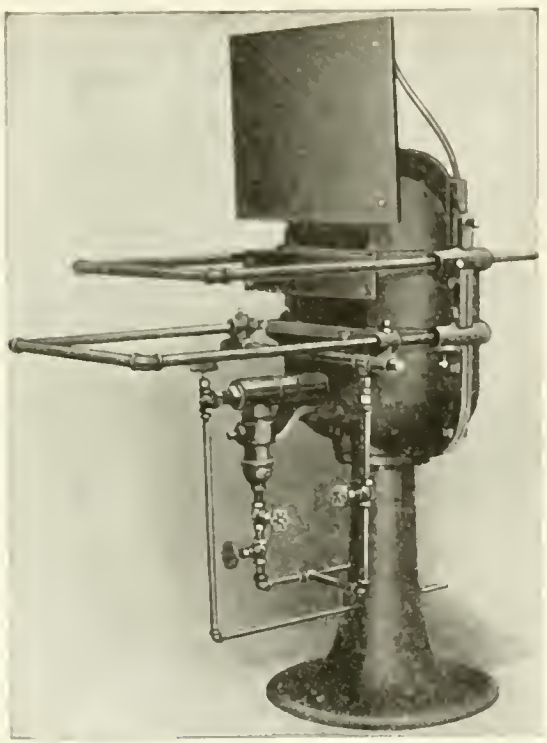
INDUSTRIAL NOTES

Oil-Furnace With Pre-Heating Feature

The No. 3 Leyner oil-burning furnace, which is used extensively for heating drill-steel, is now made with a pre-heating chamber which greatly increases the capacity of the furnace. This pre-heater is a section which fits between the body and cover of the furnace of the old design. It is, therefore, a simple matter to attach this section to an old furnace by changing



OIL-FURNACE FOR DRILL-STEEL.

a few bolts. Referring to the illustration, it will be seen that the lower chamber is used for the final heating and the upper one for pre-heating.

It is claimed that by the addition of the pre-heating feature, the space for heating is doubled, the heating capacity of the furnace is increased about 50%, and the efficiency of the furnace is increased correspondingly.

The type of burner now furnished with this furnace is suitable for either high or low-pressure air. It has merely to be throttled for high pressures, and when this is done, it is as efficient as burners designed especially for high pressures and eliminates the noise common to such burners.

This furnace burns petroleum or any of its oils, such as gasoline, kerosene, distillate, etc. Oil heating has many advantages. The steel cannot be injured by absorbing injurious elements such as sulphur, phosphorus, or other impurities which are present in nearly all coals, nor from unequal heating, as the steel is heated in a flame which imparts a uniform temperature. The steel is in full view of the operator at all times.

The floor space occupied by the No. 3 furnace is 3 by 4 ft. No foundation is required, installation being complete when air and oil-supply pipes are connected.

The absence of smoke, soot, dust, ash, and cinders is a great convenience, which is particularly appreciated in underground mine installations and in plants installed in buildings.

The manufacturers are the Ingersoll-Rand Co., 11 Broadway, New York.

Mine-Rescue Stations in California

Mines in all parts of California are rapidly installing mine-rescue apparatus in accordance with the State law which goes into effect April 1, although only about one-quarter of them have completed their equipment as yet.

The Amador co-operation station, which includes the Kennedy Mining & Milling Co., South Eureka Mining Co., Plymouth Consolidated Gold Mines, and other mines in and near Sutter Creek, is installing the following: 5 sets Proto apparatus; 1 oxygen pump, which raises the pressure from the Linde tanks to 1800 lb. per sq. in.; 1 air-meter which registers amount of air passing through reducing valve per minute; 3 tanks oxygen; and 200 lb. of caustic soda. This apparatus will be placed at the Sutter Creek garage, which is building a room to store it. A house for training purposes is being built which will be filled with smoke and the men trained therein. Each mine in the co-operative station will have a team of five men who will be fully instructed in the use and care of the apparatus.

The Empire mine, Grass Valley, will have five sets of Proto. The company is building a concrete fire-proof house for the apparatus and all first-aid material. For training purposes they are using an abandoned level of the Empire mine, which will be filled with smoke, and will construct artificial barriers for men to practice on.

The North Star mine will have four sets of Proto which will take in the North Star and Champion mines as a co-operative station. They will have a team of picked men and expect to train under practically the same circumstances as the Empire mine.

The Brunswick mine will have two apparatus, a small fire-proof house wherein to keep the same, and first-aid material and train men.

The idea at Grass Valley is to have competition between the different mines so as to bring them up to a high state of efficiency. Prizes will be given from time to time to the winners of these meets, and in this way the efficiency will be raised to a high standard.

A full station is to be erected at the Eagle Shawmut mine, Shawmut. This consists of two sets of Proto apparatus, one oxygen-pump, one air-meter and oxygen, and enough caustic soda for 10 hours for each apparatus.

This makes five full stations that will be installed by April 1 in California, all of which are Proto stations, the Proto being the only apparatus now used in California.

This apparatus has all been sold by E. D. Bullard, a safety expert with offices at San Francisco.

The 'Rotator' hammer-drills 'DP-33' and 'DR-33' are described in Bulletin No. 70-A of the SULLIVAN MACHINERY Co., Chicago. The capacity of these machines is astonishing. Augers can be used for soft ground. Some notes are given on bits and blacksmiths' tools.

As is customary with the NATIONAL TUBE Co. of Pittsburg, Pa., its latest catalogue of 72 pages, entitled "The Whole 'Kewanee' Family" is an excellent production discussing the firm's unions, fittings, valves, etc. All pipe users should secure a copy.

A supplement to its general catalog No. 56 has been issued by the CHAIN BELT Co., of Milwaukee, Wisconsin. The detachable, saw-mill riveted, grip-lock riveted, steel-bushed, and steel chains are briefly described.

The Duntley universal electric hammer-drill is described in Bulletin E-38 of the CHICAGO PNEUMATIC TOOL Co. This is an efficient machine. Some notes are given on the steels to be used.

EDITORIAL

T. A. RICKARD, Editor

EFFICIENCY in war, and the national solidarity to which it is due, is receiving proper praise at this time, but most people seem to ignore the fact that this efficiency is being obtained regardless of cost. No economic argument can be based upon it. An effort so expensive could not be tolerated in time of peace.

HIGH-GRADING is usually associated with rich gold ore, to obtain which it is not so easy nowadays. The latest phase of ore-stealing is the taking of tungsten ore and concentrate, worth $1 to $2 per pound. Thefts of such products are being reported from the tungsten-producing districts.

ELECTRICAL theories of flotation will receive a jolt from the interesting article by Mr. F. A. Fahrenwald, who writes from the Case School of Applied Science, at Cleveland, from which also emanated the two suggestive articles by Mr. Thomas M. Bains, Jr., published by us a few months ago. Evidently this phase of the flotation problem is being carefully studied at Cleveland.

COBALT, like many other districts where flotation has proved useful as a process of concentration, is faced with the question of treating the flotation concentrate locally. At present the cost of freight and treatment outside is $24 per ton, equivalent to about $1 per ton of crude ore. Undoubtedly the reduction of flotation concentrate, otherwise than by large-scale smelting works, is a fascinating problem.

MEXICAN rumors of a union of forces between Villa, Zapata, and Diaz may be disregarded. If true, it would be a good thing for the Mexican government in so far as it concentrated the recalcitrant elements into one body instead of scattering them into marauding bands. The story emanates, we believe, from Villa's press agency at El Paso. Meanwhile Villa himself is reported near the northern border, looking for a chance of safe exile.

WE are surprised to see that the *Mining Magazine* reproduces the so-called statistics of the world's gold production published at the beginning of the year by the *Engineering and Mining Journal*, the editor in London stating that his own efforts to collect the necessary statistics had proved unsatisfactory to himself. This is frank, at least; but the gentleman in New York could have said so with equal grace, for his guesses at the gold output of Mexico, Central America, South America, Russia, Japan and Korea, China, Madagascar, Congo, and Dutch East Indies must be equally "unsatisfactory" to a discriminating reader. As a matter of fact, the editor in New York had just as few reliable figures as his contemporary in London, only the latter was more cautious. The figures for the British dominions and for the United States constitute real statistical information, and these only. As to Canada, the *Engineering and Mining Journal*, in its issue of January 8, gave the Canadian output in 1915 as $15,875,000. We have obtained the official estimate from the Canadian Minister of Mines, who gives it as 916,076 ounces, worth $18,936,971, showing an error of over $3,000,000, or about 20%, in the hasty estimate made by the *Journal*.

SPECULATION in mining stock is said to be lively in the Coeur d'Alene, one of the contributory factors being prohibition, which operates favorably in two ways: in the first place, the defunct saloons have been converted into brokerage offices, and secondly, the 'dry regime' is said to promote the diversion of money from the intoxication of alcohol to that of share-gambling. This is to the gain of mining, in so far as it provides capital for exploratory and development work. What with increased wages and more thrift, the miner is becoming a factor in supplying money for new ventures. We should like to see more grub-staking among the men and less gambling in stocks, but this is not a perfect world, so we must not grumble.

PUMPING is an important subject at this season of the year, and it is particularly timely just now because so many old mines are being unwatered. Therefore we are glad to give our readers a summary of the excellent article by Mr. Charles Legrand, consulting engineer to Phelps, Dodge & Company. Among the topics discussed by him is a comparison between pumping by steam and by electricity, with records of tests that illustrate the chief points at issue. He also discusses the economy of steam-pumps, the question of steam-line, and the relative merits of air-lifts. In his many practical suggestions every mine-manager will find something applying to his own conditions. Among the big pumping operations mentioned in the paper is the Old Dominion mine, where now 11 million gallons of water is being raised daily.

OUR London correspondent sends an interesting letter, touching upon the general shortage of effective labor in South Africa, and the probability that any resumption of work at the diamond mines, at Kimberley and Pretoria, will cause a drain upon the labor-supply of the

Rand. Indeed, scarcity of common labor is going to be an unpleasant factor all over the world even before the War is ended. The effect of war taxes on mining operations is illustrated sharply by the case of the Cornish tin mine mentioned by our correspondent. Obviously the clash of patriotism and business is going to give many uncomfortable moments to thoughtful men in England and other belligerent countries. To what extent the heavy taxation incidental to war and its sequel may cause a transfer of registry on the part of mining companies operating in foreign countries is another matter of serious import to the mining fraternity in London.

WATER-POWERS are becoming more valuable, as electricity is applied increasingly to the arts and industries, notably metallurgy. We publish a letter on the protection of this natural resource by a distinguished exponent of conservation, Mr. Gifford Pinchot, formerly Chief Forester, whom we regard as a man of courage and initiative, although we are not in full agreement with the policy he and his friends advocate. We want to see the perpetual sources of energy used instead of going to waste while the limited reserves of coal and oil are being squandered recklessly.

EXTRA dividends distributed by several of the big copper companies mark the favorable effect of the rise in metal prices. Copper is now at its highest since 1873 and is approaching the prices ruling during the Civil War, when it sold as high as 55 cents. That was in 1864; in that year the United States produced only 9000 tons of copper. Mr. John D. Ryan and other authorities on the subject deprecate any further rise as likely to prove injurious to the industry. All the large producers are sold so far ahead that they are under no necessity to compete for business. The regrettable feature of any inflation is the stimulation of new mining enterprises based on a price that cannot last and the exploitation of worthless mines as a counter for wild gambling.

SAFETY work has now won a firm hold on the intelligent managements of mines. The main feature has been the effort to arouse the interest and co-operation of the miners themselves. This has been done at the Treadwell group of mines, for example, by organizing a Committee of Fifteen, eight of whom are appointed by the Labor Union and seven by the Mine Management. This committee is divided into five sub-committees, covering as many mine departments, so that when an accident occurs the fact is reported to the foreman, mine superintendent, and the sub-committee of that department. These make a prompt investigation and deliver a written report on the causes and consequences of the accident to the main Committee of Safety. In making reports, it is understood that the facts and comments shall be stated honestly and fearlessly, as thus only is it possible to secure evidence of value for future emergencies. The members of the committee are paid by the management for the time they devote to this work, which throughout is placed on a workmanlike basis. A cash prize of $25 is paid quarterly by the Treadwell company to the employee who submits the best suggestion for preventing accidents in or about the mines. Some good ideas have been elicited in this way and the general interest of the men has been stimulated thereby. First Aid lectures are given by the Company physician once a week and the men are taught the proper use of restoratives and remedies. The whole scheme has been admirably considered and elaborated.

ACCORDING to *The Northern Miner*, the mining public of Canada is objecting to the new war-tax whereby all corporate profits above 7% per annum are taxed 25%. It is claimed that this heavy muleting of the gains obtained from mining operations will stop the flow of capital from the United States. Our contemporary at Cobalt does not expect American speculators to make a sacrifice with equanimity, even though Capt. J. R. Delamar is quite willing to pay "the trivial amount involved." It is claimed that silver mining has not profited from the War, while gold mining has lost decidedly by the rise in the cost of all supplies and machinery. However, other kinds of metal mining are profiting greatly from the high prices caused by intensified consumption in the making of munitions, so we shall be surprised if the general sentiment in the Dominion is aroused to any real opposition to this taxation. By the way, in Canada also the War has reversed the current of trade, for while the trade balance was adverse in 1913 to the amount of $198,500,000; and in 1914 the excess of imports was $70,300,000; in 1915 the exports exceeded imports by $201,700,000. This was due to the big wheat crop and the manufacture of war supplies.

IN our issue of May 8 last year we wrote concerning administrative continuity and referred to the efforts made by several well-known mining companies, notably the Goldfield Consolidated, to lengthen their lives by acquiring new property as the old approached exhaustion. We commended the idea as perpetuating the goodwill that exists in a thoroughly organized management or staff and preventing the waste of an asset that is valuable to the mining industry. We refer to the matter now because we are informed that the Goldfield Consolidated Mines Company has opened an office in San Francisco for the special purpose of investigating likely business, establishing what is called an 'exploration' department, the function of which will be to consider and examine properties offered for option or sale. In this case the scope of inquiry is not to be limited to gold mines. That is wise. The other metals can be turned into gold at an enhanced ratio today. More money can be made just now, and for some time to come, from the less common metals because there are fewer producers of them. Mining is full of adventure in these days and offers better chances than when, in default of other 'talking points,' the broker and promoter retailed nonsense about its being an investment, a manufacturing proposition, a dead sure thing, and so forth. Mining is

speculative and is least risky when frankly recognized as such.

OFFICIAL statistics are now available in regard to the export trade of zinc and copper last year. These give eloquent testimony to the growth of export. As regards zinc they are as follows:

	1915	1914	1913
Exports, weight in tons	125,203	64,847	7,782
Exports, value in dollars	33,504,908	8,540,668	955,667

In other words, the export of zinc has grown from a million dollars per annum to 33 millions within two years. In 1915 the importation increased to 55,668 tons as against 12,134 and 13,497 respectively in 1914 and 1913, the increase being due to the diversion of Broken Hill zinc concentrate from Belgium and Germany to the United States, by reason of the War, of course.

In regard to copper, the exportation of metal decreased in quantity, on account of the blockading of German ports, but the increase in price caused the value of the outgoing copper to be a million dollars more.

	1915		1914	
	Tons.	Value.	Tons.	Value.
Exports 341,000		$117,000,000	421,000	$116,000,000
Imports 158,000		44,000,000	152,500	40,000,000

In addition there was an enormous increase in the export of brass, thus:

	1915		1914	
	Tons.	Value.	Tons.	Value.
Exports	34,000	$55,000,000	14,000	$6,700,000

If this brass contained, say, 75% of copper, the total export of copper would have been 366,500 tons in 1915. Germany, Belgium, and Austria took no copper from us in 1915, while Holland received only 2000 tons as against 89,000 tons the year previous.

CANADIAN statistics of metal production in 1915 are just to hand from the Department of Mines. An increase of $2,953,964, or 18.5%, is recorded in the production of gold, the total being $18,936,971. Of the total 44% comes from Ontario. This province increased its output by 51%, thanks mainly to the Hollinger, Acme, and Dome mines. The production of silver remained practically unchanged at 28,401,735 ounces, as against 28,449,821 ounces in 1914. Of the total 86.8% came from Ontario, chiefly from Cobalt. Of the silver bullion 10,623,307 ounces was extracted by smelters in southern Ontario and 9,270,332 ounces by the mills in the Cobalt district. In copper a big gain was made, the output increasing 35% in weight and 72% in value as compared with the previous year. The total was 51,306 tons, worth $17,726,300. Again Ontario ranks high, having contributed 19,651 tons, chiefly from the nickel-copper ores of Sudbury. Nickel, of course, has been in great demand, so that it is not surprising that the mines of Sudbury should have increased their output by nearly 50%, the total being 67,703 tons of matte containing 19,608 tons of copper and 34,039 tons of nickel from 1,364,048 tons of ore. The total value of Canada's mineral production in 1915 is estimated at $138,513,750 compared with $128,863,075 in 1914 and $145,634,812 in 1913. Thus the production was a little less than the best on record, owing, of course, to the crippling of industry by the War at the beginning of the year, the chief losses being in cement and clay products.

Is Mining Engineering on the Wane?

In the latest bulletin of the Mining and Metallurgical Society we find an interesting contribution by Mr. Arthur L. Walker, Professor of Non-Ferrous Metallurgy in Columbia University. He has heard it said that the profession of mining engineering is on the wane and he asks the members of the Society 'what they know about it.' He himself refers to the growth of specialization as having restricted the scope of the individual engineer; also to the effect of the persistent misrule in Mexico and of the organized calamity in Europe as having diminished the opportunities for professional employment. Finally, he suggests that the expansion of output does not make a corresponding increase of work for engineers, while the slackness in the exploration and development of new mines during recent years has tended to lessen the demand for engineering service. Another point mentioned is that of the character of the education required today for the mining engineering profession; the number of schools for the purpose has increased greatly and most of them try to give a complete training in three or four years; at Columbia the curriculum now calls for six years of study, it being the belief that three years of general education and three years of engineering is not too much time to devote to the preparation necessary.

Here are some good questions for thoughtful men to answer. We shall be glad to read what the members of the Society have to say to Professor Walker. Meanwhile, it is obvious that the subject concerns a wider public than the group of men to whom these questions were addressed. Let us begin by recording a cheerful negative to the first question. Mining engineering is not going to decline in importance, for the scheme of living called civilization depends upon the use of metals. In the immediate future we discern the probability of an intensified demand for the metals, at least for those to be extracted out of that part of the earth's crust that is called the United States. Material progress advances by means of metallic structures, whether of buildings, bridges, ships, cars, or aeroplanes. All the conveniences of life, from pipes and wires to heating and lighting, are largely based upon the varied use of the products of the mine. The mankind of today and of the future within our immediate vision will require metals in great and increasing quantity. We do not fear that they will go out of use. In so far as any of them become scarce there will be a call for skill in finding them and ability in extracting them from their natural state. No; there is no sign of the mining engineer going out of fashion, but there is danger of superfluity in one direction: During the last decade a number of unnecessary schools

of mining have been established, reducing the attendance at the best schools while exhausting the supply, never abundant, of those competent to teach such difficult subjects as mining and metallurgy. The consequence has been to augment the number, without improving the quality, of those initiated into the profession. The boom days of 1907 caused the mining schools to overflow with students for two or three years, and thereby provoked the expansion of facilities for rudimentary schemes of teaching mining at State universities, agricultural colleges, and other institutions not well equipped for the purpose. Hence the apparent congestion today. This has been emphasized by the closing of several mining regions in consequence of warfare in many parts of the world and the financial stringency in others. When peace is restored, the congestion will be relaxed, but one feature will continue to be recognizable, namely, the need for specialization. The day of the smatterer is gone; every man must specialize in some branch of an immensely big subject. In the hey-day of the generation now passing it was possible for a mining engineer to be a mechanical engineer, a metallurgist, and a geologist; at least, he could equip himself with enough information concerning any and all of these departments of knowledge to meet the needs of the period. But even the Admirable Crichton of those days would feel, even if he did not look, foolish today when the machinery of mining has developed in size, cost, and complexity to something so far beyond the simple structures of its infancy; while metallurgy has grown to include concentration by water, fire, oil, and involves the use of chemical and electrical processes of the greatest delicacy conducted on a colossal scale; and geology as applied to mining has passed from the prattle of childhood to the stern work of accurate survey, microscopic examination, and chemical research. In short, the jack-of-all-mining has given way to the mechanical engineer, the chemical engineer, the economic geologist, the concentration expert, the mine-valuer, the specialist in leaching, matte-smelting, electrolysis, flotation, and so forth. Of course, no little mining school, the annex to a non-scientific college, can expect to train such specialists. Even the great schools of mines attached to the big universities are set a task beyond the scope of the ordinary three years course. It has become necessary to treat the training for mining as the post-graduate of a precedent thorough scientific training. Nevertheless the abilities of the advanced schools are being exceeded by the requirements. Obviously they also must specialize, so that they may be able to train specialists. Let one school concentrate its attention on metallurgical and another on purely mining subjects. For instance, let Columbia specialize in fire metallurgy, Harvard in economic geology, Houghton in mining methods, Berkeley in wet metallurgy, with such further distributions among the others as locality and circumstances may suggest, so that the graduate student may choose a specialty and go to the school best fitted to teach it to him. Of course, no agreement is likely to be made among the schools for the accomplishment of this purpose, but something of the kind must be kept in view. Here is where organization is preferable to *laissez faire*. In any event, even if the schools continue their go-as-you please policy, it is evident that the students must awaken to the realities of the position and recognize that a shallow knowledge of a tremendously wide subject will fail to equip them for a successful career. There will always be an opening for the man who is well prepared; there will be steady lessening of chances for the mob of the unprepared.

Chalcocitization

Among the notable contributions to the science of ore deposits is the work of research into secondary enrichment, more particularly of copper deposits, started by Messrs. L. C. Graton and Joseph Murdoch, and continued by Messrs. Posnjak, Allen, and Merwin in the geophysical laboratory of the Carnegie Institution at Washington. Supplementary to the work of these investigators, Messrs. C. F. Tolman and A. F. Rogers, at Stanford University, have been making a research into the origin of chalcocite ores. The idea had been put forward by Messrs. Graton and Murdoch that the chalcocite precipitated from ascending solutions showed a cleavage different from that possessed by the same mineral when deposited from descending solutions. This, of course, would be a criterion valuable to the miner. Now, Mr. Tolman, in a paper presented recently before the American Institute, shows that the cleavage can be inherited by the chalcocite from a bornite stage and that by this pseudomorphic pattern it is possible to find clues to the earlier minerals destroyed by the chalcocitization. Applying his method of examination to the ore of the Bonanza mine, of the Kennecott Copper Corporation, Mr. Tolman discovers that the chalcocite of this remarkable orebody is derived from bornite, as is proved by its intricate patterns in blue and white. Residual bornite was detected by the microscope. Thus the inference is that the big body of wonderfully rich ore is due to the chalcocitization of a coarsely crystalline mass of bornite, from which the iron has been completely leached, to be replaced by an equivalent amount of copper. He finds that the original group of minerals was bornite, klaprothite, and galena, succeeded by chalcocite, which by increase of oxidation became converted into covellite and chalcopyrite, then tenorite and cuprite, then malachite and azurite. The latest changes are being effected by the vadose circulation in water near the freezing point, the copper migrating as malachite, with resulting impoverishment of the mass. This study of an extraordinary deposit is most suggestive and we hope that before the ore is exhausted it may serve not so much as the excuse for financial operations of a flamboyant character as the subject for investigations that may finally establish the actual part played by chalcocite in making those copper enrichments on which so much large-scale mining is based.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Control of Water-Power

The Editor:

Sir—I write to ask your help to defeat a most serious attack on our public resources. Since the fight over the Alaska resources was won there has not been so pressing a threat against the conservation policy as the present effort in Congress to give our public water-powers for nothing into monopolistic control.

The Shields bill, now before the Senate, gives to the power interests without compensation the use of water-power on navigable streams. The amount of water-power these streams will supply is larger by far than all the power of every kind now in use in the United States. It pretends to, but does not, enable the people to take back their own property at the end of 50 years, for in order to do so under the bill, the Government would have to pay the unearned increment, and to take over whole lighting systems of cities and whole manufacturing plants. Private corporations are authorized to seize upon any land, private or public, they choose to condemn.

Bills which gave away public water powers without due compensation were vetoed by President Roosevelt and President Taft. The Shields bill would do precisely the same thing today.

Another water-power bill, the Ferris bill, relating to the public lands and national forests, was in the main a good bill as it passed the House. As reported to the Senate it encourages monopoly by permitting a corporation to take as many public water-power sites as it may please. Under it the corporations could not even be kept from fastening upon the Grand Canyon, the greatest natural wonder on this continent. This bill takes the care of water-powers on national forests from the experienced and competent Forest Service, and gives it to the Interior Department, thus entailing duplication and needless expense.

In my opinion, there is undue carelessness as to the disposal of public resources at present in Washington. The water-power legislation now before the Senate is too favorable to the men who, as Secretary Houston's admirable recent report shows, control through 18 corporations more than one-half of the total water-power used in public service throughout the United States. The water-power men charge that Conservation hampers development. The Houston report shows, on the contrary, that the most rapid development is in the national forests, where conservation is best enforced. On the other hand, 120 public-service corporations own and are holding undeveloped and out of use an amount of water-power equal to four-fifths of all there is developed and in use by all the public service corporations in the whole United States.

As I said in an open letter on January 29 to the President: "Natural resources lie at the foundation of all preparedness, whether for peace or for war. No plan for national defense can be effective unless it provides for adequate public control of all the raw materials out of which the defensive strength of a nation is made. Of these raw materials water-power is the most essential, because without electricity generated from water-power we cannot manufacture nitrates, and nitrates are the basis of gunpowder. There are no great natural deposits of nitrates in the United States as there are in Chile. It would be folly to allow the public water-powers, which can supply this indispensable basis of national defense, to pass out of effective public control."

A concerted movement is on foot to break down the conservation policy. Feeble resistance or none at all is being made by official Washington. Unless the press and the people come to the rescue, the power interests are likely to win. This is a public matter wholly removed from political partizanship. Your help is needed, and that of your paper. For nearly ten years this fight for the public water-powers has gone on. We ought not to lose it now.

GIFFORD PINCHOT.

Milford, Pa., February 15.

Cyanidation of Flotation Concentrate

The Editor:

Sir—A few weeks ago you referred to me the question as to whether flotation concentrate could be successfully cyanided. I replied that although I had no working data on the subject I saw no reason to apprehend any difficulty due to the fact that the concentrate was recovered by flotation and not by some other method. I am now able to state that my opinion has been borne out by tests on a sample recently submitted to me.

The ore in question was a California gold ore assaying 0.57 oz. gold and a little silver. It was ground to pass an 80-mesh sieve for flotation and yielded a concentrate assaying 9.66 oz. gold and 9.85 oz. silver. A sample of this concentrate, without filtration or regrinding, was treated by bottle-agitation for 72 hours with cyanide solution at 0.2% KCN and at a ratio of

5:1. No preliminary treatment of any kind was given and no reagents were added except lime and sodium cyanide. The solution was not changed during treatment, and at the conclusion of agitation the sample was filtered and washed on the filter in the usual way.

Residue	
Gold, Oz.	Silver, Oz.
0.29	3.54

Extraction	
%	%
97	64

It is probable that if some lead compound had been added during treatment, a higher extraction of the silver would have resulted. It is also not unlikely that the gold extraction can be increased in the course of further research work.

This test shows that some flotation concentrates, at least, can be cyanided raw with very little trouble. I am inclined to think that given an ore that presents no *a priori* obstacle to cyanidation, the concentrate recovered therefrom by flotation will give no more difficulty in cyanidation than a concentrate from the same ore recovered by any other means.

San Francisco, February 29.

Mechanical Efficiency of Crushing

The Editor:

Sir—I have just obtained a copy of your issue of November 6 which contains Mr. Stadler's letter, in which he is real rough to Messrs. Kenny and Del Mar. The matter of my being a qualified expert has come into the discussion, at least Mr. Stadler's letter carries an implication that the only real experts in crushing lived and moved and had their being some fifty years ago; but the written word is so easy of misinterpretation that I offer my apologies before he goes back to the piano for his gun.

Our little conspiracy to undo all that Mr. Stadler has done has recently had an accession. Some two years ago there was published in your columns a note on the rock-crushing tests then being conducted at McGill University, the preliminary results of which indicated that Stadler's theory of Kick's law was correct. Recently the secretary of the Canadian Mining Institute called my attention to an editorial in their October bulletin referring to my paper presented in the September bulletin of the A. I. M. E., but more particularly giving preliminary conclusions on the work that has been done at McGill up to date. The editorial concludes thus: "Nearly 200 tests have been made at McGill during the past two years and we understand that each series will demonstrate convincingly the fallaciousness of expressing power in terms of 'energy units,' as proposed by Mr. Stadler in accordance with Kick's law. Rittinger's hypothesis, on the other hand, is supported in so satisfactory a degree by the results obtained by actual experiment as to appear quite dependable. It seems probable, therefore, that the investigations made at McGill and Purdue universities will result in terminating the long standing controversy between the supporters of respectively Rittinger and Stadler; while if, as now seems likely, it will conduce to the definite establishment of a correct basis for calculating the efficiency of rock-crushing machines, a work of great utility, by reason of its practical value to mill-men, will have been accomplished."

In the same issue (November 6) you abstract a paper by M. K. Rodgers presented in the September bulletin of the A. I. M. E. on 'Standardizing Rock-Crushing Tests.' I started some comment on it, but was unable to complete it within the time limit, and as he was absolutely neutral on the matter of laws and didn't take a shot at some of us, I won't say much about it, except just this: Report screen analysis of feed and discharge in cumulative per cent or tons and in reciprocals of diameters. If he will agree to get Tyler to stamp on every standard screen he sends out the reciprocal of diameter in inches, I'll agree to say that it's the ki-ki screen for crushing-surface diagrams.

Also, I took those screen analyses of Mr. Rodgers and made crushing-surface diagrams out of them. At least, I did the best I could, for they were not made with the screens he advocated, and I had to be very unscientific and guess at the openings, or the reciprocals of the diameters. These crushing-surface diagrams give the following results, on + 200 mesh:

	Mesh-tons per hp.-hour.
Calumet & Hecla conglomerate	12.5
Coeur d'Alene quartzite	15.6
Miami	34.0

while Mr. Rodgers finds the relative crushing duty due to character only to be 1.00, 1.92, and 3.75, by a very neutral method. The other crushing conditions are not the same, the tonnage is decidedly different, there is some difference in moisture contents, and the feed at Calumet & Hecla is much cleaner of undersize than at Miami. I believe these figures represent not differences in the crushing characteristics of the rocks so much as they do differences in manipulation.

This matter of crushing efficiency and the laws of crushing must appear to the average reader as a fight between a bunch of quack doctors. I may be a crank on the subject, but when my study, scientific or unscientific, of fine grinding or crushing leads me to believe that fully 50% of the energy spent in fine grinding is absolutely wasted, and produces a product more difficult of manipulation, shall I keep my mouth shut? Where the mill-man can gain from this discussion will be to just forget about Kick and Rittinger, study his crushing operations by means of the crushing-surface diagram, and attempt to improve his mill efficiency along the lines that are suggested in my paper on 'The Applications of the Crushing-Surface Diagram.' (I have a few reprints of this paper that I will be pleased

to send to any mill operator interested.) So far as I know, neither Stadler's work nor mine has resulted in any marked improvement in mill-efficiency, but I know of no place where they have really tried to improve conditions by my methods. Some folks are fooling with it and may get results from them. Can't you give a Dutch boy a chance?

A. O. Gates.

Mishawaka, Indiana, January 18.

Mining in Western Oregon

The Editor:

Sir—Reading 'Mining in Western Oregon' by C. E. Morse in your issue of January 29 is like meeting an old friend, and I feel like saying "glad to see you, old fellow, but sorry you have not been as prosperous as you certainly deserve," for I was foreman of the Lucky Boy mill during the winter of 1900-'01 for six months, when I had to give up the position on account of a severe illness.

There was no "secret solution" used, however, in the De Keyser process, as I was reliably informed although it was not in operation when I went there, except the secret of the solution of the problem, which it did not reveal. You meet this process from time to time with about the same frequency as the process for the extraction of gold from sea-water. The concentrate was simply ground in the Crawford mill with an excess of mercury and strong cyanide solution, the pulp then passing over the 'electric plates,' where it was hoped the gold would be deposited by electrolysis. The plate did not shake, however. I put in the shaking device, using hardwood eccentrics. I re-ground the concentrate from the Wilfleys with mercury, and shook the plate merely to keep the heavy pulp in motion instead of increasing the grade of the plate. In this way I recovered an additional small amount of free gold. The classifiers, not mentioned by Mr. Morse, simply V-boxes with two spigots, I also put in. By treating the coarse spigot product on the Wilfleys and the fine on the vanners, I was able to increase the value of the concentrate from $30 per ton to about $50.

Since the development of concentration by flotation, I have often thought the ores of the Lucky Boy district could be successfully treated by this process. By screening the plate-tailing instead of classifying in water, delivering the + 80 to the Wilfleys, and the undersize—dewatered—to the vanners, a concentrate from the vanners could be produced well fitted for flotation, and by using continuous riffles on the Wilfleys most of the pyrite could be separated mechanically from the galena and blende.

My incomplete experiments showed that a fair extraction could be obtained by cyanide, though all my notes were lost when the assay-office was burned in March 1901. By a coincidence, I also spent a couple of months at the Ogle Mountain mine, assaying the mine and instructing the mill-crew. The mill had then 5 stamps and a new Standard concentrator. The mine in the upper workings yielded some high-grade ore. As an instance of what we meet 'as through this world we roam' the young man who started the mill 'dressed' the plates with coarse sand and strong cyanide, the said cyanide being mixed and allowed to stand in a coal-oil can. The condition of the plates can be imagined.

H. S. Reed, Jr.

Shawmut, California, February 1.

Pine-Oil

The Editor:

Sir—Your definition of pine-oil, as embodied in 'A Glossary of Flotation,' in your issue of February 12, 1916, is rather misleading and, in view of the present general interests in pine products as applied to flotation I take the liberty of discussing this question at some length.

In arriving at a proper understanding of the different products produced by treatment of the resinous woods of the South Atlantic and Gulf states (usually dead and fallen timber or pine-stumps) it is necessary to bear in mind that two basic methods of treatment are used.

The first is the steam and solvent process: To prepare the wood for treatment it is reduced to the consistence of fine chips by passing through chipping machines and is then placed in a retort or extractor. Superheated steam is then passed through a charged retort until the turpentine and pine-oil have been volatilized and passed to the condenser, where they are recovered. Steam is then shut-off, the wood dried by evacuation and finally subjected to several extractions with a solvent, usually petroleum, gasoline, or naphtha. The resin and any remaining oils are thus extracted, and later this solution is separated into its component parts—extraction solvent, pine-oil, and rosin—by distillation. The products resulting from this process are turpentine, pine-oil, rosin, and 'spent wood,' which is suitable for paper-pulp or may be burned under boilers. All of these products appear normally in dead pine-wood and are not products of decomposition.

The second is the destructive distillation process: The wood, in the form of cord-wood, is placed in a horizontal retort. The retort is then sealed and heat applied externally. The temperature is raised slowly until the wood is thoroughly carbonized. The volatile constituents are passed to a condenser. It is general practice to separate the condensed liquors into two fractions; the first representing the distillate passing from the retort up to the temperature at which the wood begins to char, and the second representing the distillate during the charring or decomposition period. The first distillate is usually known as 'sweet crude,' and upon refining yields turpentine and a small percentage of pine-oil. The second fraction, known as 'D-D crude,' when refined yields a small amount of pine-oil of inferior quality, pine-tar oils, and pine-tar. A great variety of products can be produced from this 'crude' by varying the methods of refining.

With these methods of production now in mind we are

ready to return to the definition of pine oil. Specifications of the U. S. Navy Department define pine oil as follows:

"Pine-oil is a properly prepared light straw-colored oil produced by re-distillation of heavy, high-boiling point fractions resulting from the steam distillation of wood turpentine, and having a strong aromatic odor resembling turpentine." As it is not a product of decomposition, it possesses well defined physical properties. Pine-oil produced by steam-distillation should have a specific gravity of not less than 0.930 or more than 0.945 at 60° F., and upon distillation should show at least 75%, distilling between 200° and 220° C.

The definition you have given for pine-oil really covers pine-tar oil, which is defined by the U. S. Navy Department as:

"A properly prepared distillate from straight pine-tar, which latter has been obtained by destructive distillation of pine-wood." It is not practical to attempt to outline specifications for pine-tar oils here as they are usually refined in conformity with the individual ideas of each producer.

New York, February 18.

Unusual Gas in a Metal Mine

The Editor:

Sir—An unusual gas mixture for metal mines is found in the Tonopah-Goldfield district of Nevada. This gas is locally known as 'ground gas' or 'natural gas.' During the stay of Mine Rescue Car 5 of the Bureau of Mines in the summer of 1914, the presence of this gas was noted by a member of the mine-rescue class, an underground shift-boss. Samples taken by the water-displacement method had the composition shown by the accompanying analyses.

	(a)	(b)
Oxygen	0.95	0.52
CO_2	0.65	1.08
Nitrogen	98.40	98.40
Total	100.00	100.00

The high nitrogen content, 98.40%, and the low oxygen content, 0.52%, are noteworthy. This is the greatest deficiency of oxygen that the writer has ever noted except in gases from a fire area. Apparently the evolution of this gas is associated with the genesis of the ore deposits of the district. Nitrates have been found in the mine-waters, and the surrounding country is full of hot springs, the waters of which show nitrates.

Careful inspection revealed that usually the gas was given off from the 'water-courses' and 'vug-holes' in the orebodies. So far as could be ascertained, this gas is not found in the country-rock. It collected in blind raises or in the tops of dead-end stopes. The air currents in the drifts under the raises created a definite line of separation at the bottom of each raise, above which a carbide lamp would be instantly extinguished. In one mine investigated, the shift-boss stated that in a certain drift on the 800-ft. level the miners often drilled into fissures, and that the rush of gas from the drill-holes would immediately extinguish their lights and drive them from the place. It only required, however, a compressed air line carried to the face to clear the drift of gas so that the men could go back to work.

In the blind raises the air-line would completely rid a raise of the gas, but over-night a raise would refill. In a long drift on the 600-ft. level of one of the mines, a vug-hole or crevice was pointed out as producing 'natural gas.' On close inspection it was found that a carbide lamp extended into this crevice was immediately extinguished. The gas could be expelled by blowing a full breath into it, but in three minutes it would refill so that the lamp would not burn.

The physiological effect of breathing this gas is similar in every way to that produced by breathing pure nitrogen. A man is likely to drop dead without warning because of the lack of oxygen. In the weak mixtures, in which there is more oxygen than is shown by the analyses, but considerably less than in normal mine-air, a man breathes deeply, but shows no alarming symptoms of distress. A candle is extinguished, and the flame of a carbide lamp reaches forward and turns red, as might be expected from the incomplete combustion consequent on want of oxygen.

In a Goldfield mine a pipe-fitter lost his life in trying to disconnect a pipe-line extending into a raise that had filled with this nitrogen gas. The man was found face downward at the bottom of the raise in a position indicating that he had fallen. He had carefully placed his candle in the pure air at the bottom of the raise, evidently because it would not burn when he took it with him. The analyses cited above represent duplicate samples taken by me in the top of this raise, 50 ft. above the stope. A set of self-contained oxygen breathing apparatus was used in collecting the samples.

E. STEIDLE.

Washington, D. C., February 10.

[The above communication from the district mining engineer of the Bureau of Mines conveys a useful warning.—EDITOR.]

HOISTING ROPES at the Copper Queen mine are shortened every month by cutting six or eight feet off the end to change the points of maximum wear, said G. F. G. Sherman in a paper at the San Francisco meeting of the A. I. M. E. Sheaves are 7 ft. diameter and are lined with leather, as wood lining broke down rapidly. By reason of winding the rope on the drum in two layers instead of one, the rope-cost per ton of ore hoisted increased from 0.17c. to 0.3c., amounting to an additional cost of $1000 per year. But to obtain this reduction, an additional expenditure on the hoisting-engine of $15,000 would have been necessary. When a rope is wound upon itself, a good deal of sliding takes place of one coil upon the other. Lubrication of cables in general is of great benefit in preventing wear.

Antimony in China

By F. L. Cole

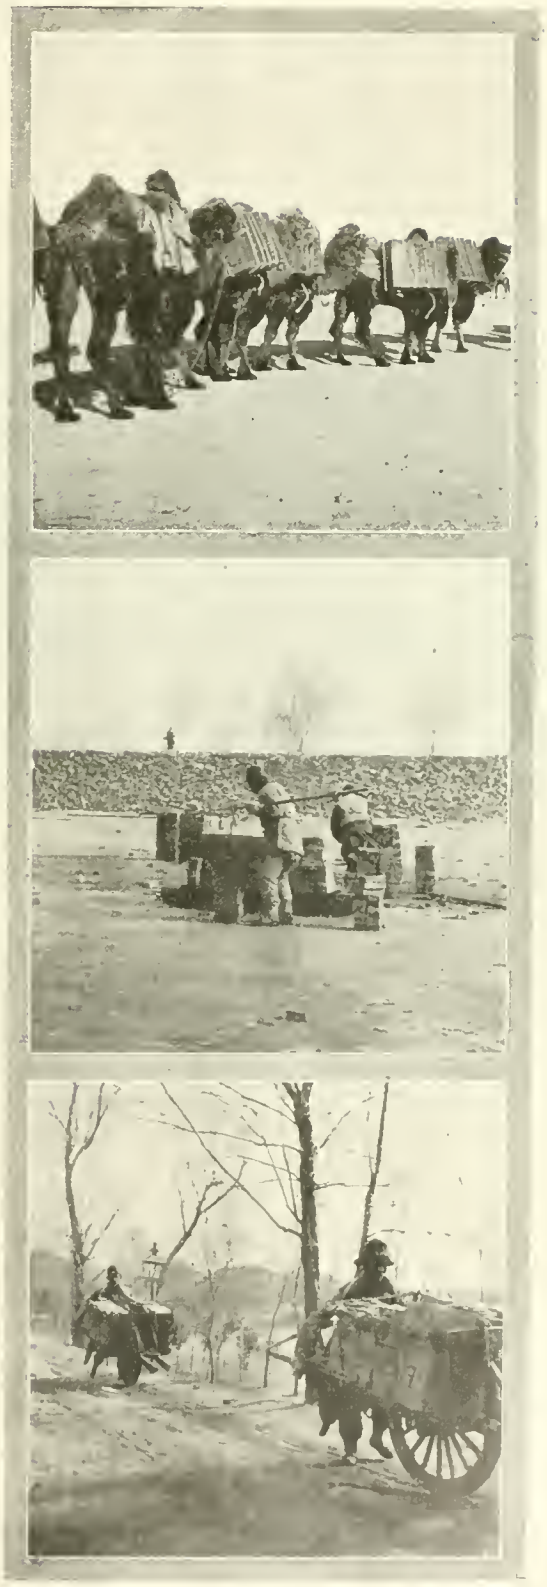
HISTORICAL. The high prices for antimony have directed attention to China as a source of supply. Owing to the mining being entirely in Chinese hands, there has been little accurate information published regarding ore occurrence or smelting methods. The first record of antimony ore in the Chinese customs returns was in 1895 when a small quantity was exported from Shanghai. In 1904 the returns show that regulus, crude,* and ore were exported. These three, together with antimonial refuse, which is also called 'ash-and-slag,' being the residue from producing crude antimony, have since then become regular articles of export. Antimony oxide has recently appeared in the customs returns, but it is probably the natural oxide or oxidized ore. The first recorded exports were from Hunan province, which has continued to be the leading producer. No proof exists that the ancient Chinese mined antimony, but they produced iron, copper, lead, zinc, and other metals for many generations. Local tradition has it that two Swiss jewelers at Shanghai, on being shown samples of antimony ore, immediately traced the source, and started the trade in 1895.

Exports first were made from Shanghai by a few foreign merchants. The foreign merchant in China used to handle everything that gave a profit and in early days the profits were not small. The ore was brought from the interior to the merchant, who sampled it, paid as little as possible, and shipped the cargo to Europe or America. The business gradually grew and the headquarters of it moved up the Yangtze river to Hankow on the arrival of German metal-buyers, who brought out men familiar with the trade. Later, the centre moved to Changsha in Hunan, 250 miles farther inland. Now buyers go direct to the mines with hard money in hand and compete with each other for ores and products from the opulent mine-owners, who make their own prices.

ORE DEPOSITS. Antimony is know to occur in nine provinces: Chekiang, Kwantung, Kwangsi, Yunnan, Szchuen, Kweichow, Hunan, Hupeh, and Kiangsi. Of these Hunan is the principal producer, but the production in Kweichow, Yunnan, and Kwangsi is growing. It is reported by the native press that the duties in Kwantung on antimony have been remitted for three years from last October in order to stimulate exploitation.

C. Y. Wang, in the 'Mineral Industry' for 1913 mentions the localities of occurrence in Hunan, Kwangsi, Kwantung, and Kweichow. A. S. Wheler, mining engineer for the Board of Agriculture, Commerce, and

*['Regulus' means antimony metal of 99% purity; 'crude' is the artificial antimony sulphide of much lower purity.—EDITOR.]



TRANSPORT IN CHINA.

Industry, Peking, in the September 1915 issue of *The Far Eastern Review*,[1] has given the best general description of the Hunan deposits. There is little reliable information regarding the other occurrences although the general geologic conditions are somewhat similar.

The Hunan deposits may be generalized as fissure-veins with quartz gangue cutting shale, quartzite, and schist; and scattered deposits in limestone. With the exception of the Pan Chi mines (decribed by Wheler, and also in the Mining and Scientific Press of July 10, 1915) none of these deposits has been exploited to any depth. The entire output of Hunan is 6000 tons of ore per month.

W. R. Schoeller[2] described the Hunan ores and gives interesting information as to their purity. No careful study has been made as yet. The ore is principally stibnite, which in favorable places both at surface and underground is more or less oxidized.

The mines, like all Chinese underground workings, are mere gopherings, with no apparent system except to get out the visible ore above water-level as quickly as possible, in any manner, and with no thought of development. A pinch in a vein or a fault is enough to cause work to be abandoned. Native-made black powder is used, and antiquated clumsy tools that add to the general inefficiency. The working-places are impossible for any but natives and the output per man is decidedly small. The ore is carried or dragged to the surface in bamboo baskets, and small amounts of water are handled in hand-operated bamboo plunger-pumps that work in relays, the sump of one being the discharge of the other. Open-flare oil-lamps, the smoke of which, together with the general insanitary conditions underground, make it anything but pleasant.

The purpose seems to be to obtain the least possible results and provide the most work for the greatest possible number of people. But when the cost of the labor is considered, the results are not as bad as would be supposed. Until recent prices stimulated search, only high-grade ores were mined, but at present all possible grades are utilized and all old waste-dumps are being carefully sorted. Each outcrop has numerous companies working on various lengths, usually units of 10 Chinese feet (said feet varying with each locality) and the working of each company is called a 'mine.' So reports of a large number of mines in a district are apt to be misleading. Actual work is done on a kind of co-operative basis by contractors, wages seldom being paid for day's work. The Chinese insist on having a gamble with everything they undertake, so there are innumerable combinations of leases and sub-leases, which the foreign brain is incapable of comprehending. Theft is not unknown, but unless carried on in too open a manner, no attention is paid, as "everybody is doing it." Payment for labor is usually at a price or at so much per picul (133⅓ lb.) of clean ore, at the pit-mouth. The ore so received is sold to the nearest crude smelting-plant, which also absorbs the local high-grade output.

Hunan province, being rather independent, pays little attention to the various lengthy rules and regulations made by the Central government at Peking. The discoverer of an outcrop can apply for a prospecting-right over a given area through the local officials and the provincial guild to the provincial mining department. This permit entitles him to open the property; after a time, application is made for a working-permit accompanied by fixed payments. This permit necessitates a survey. Recent rules require any exploiter or company to show that there is actually a certain amount of capital available for the proper opening of the mine. This is obviated by forming a company and giving the shares a cash value equal to the requirements, with very little, if any, actual cash in the treasury. This rule is held over the heads of the small people but those in power can cheerfully dodge its ramifications. A tax of 5% on the value of the ore at the mine is collected, and a guild-tax and a 5% export-tax are collected by the customs on the market-value of the ore or products before they are exported. There are probably local taxes on smelting-plants, and various transport-dues along the roads and rivers.

As mining has been done profitably for some years in Hunan, the local rules are more helpful than otherwise to the industry. Transport of ore from the interior to steamer connections is done by coolies overland and by boats on the rivers.

Smelting Methods. The furnaces for producing 'crude' metal are simple in construction and are made with no regard to economy either in fuel or the recovery of oxide from the escaping fume. They are built in units of four, occupying a floor-space of 12 by 2½ ft., and standing 5 ft. high. One furnace can be repaired while the other three-fourths of the unit is working. The bricks used are local and the cost of one unit varies from $20 to $40. The grate-bars and doors are also made locally, the grates consisting of 12 to 16 bars, a half-inch thick, 14 in. long, and spaced about a half-inch apart. The smoke and fume go to a common flue at the top of the furnace and are carried down in the centre to a common underground flue connecting with a chimney that serves all the furnaces.

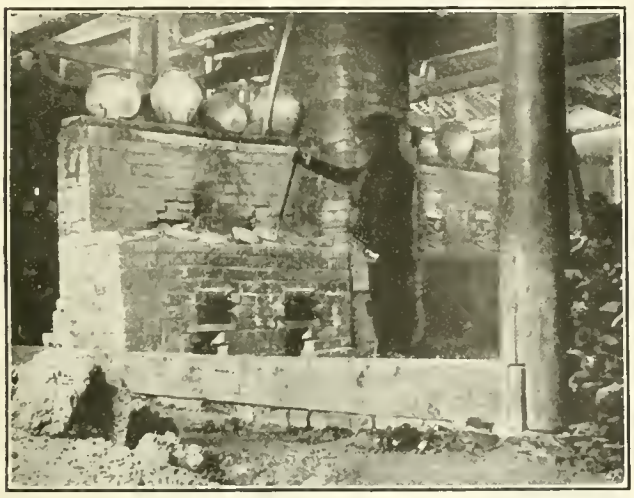
The pots used are made locally; they average 12 in. inside diameter, 18 in. high, and the hole at the top is 7 in. They hold 50 lb. of ore. As shown in the sketch, the lower pot is cut on one side to receive the bottom of the upper pot. The upper pot has a small hole about a quarter-inch wide and an inch long cut in the bottom for the liquated sulphide to drop into the lower pot. These pots never join tightly and much fume escapes. The pots last up to two weeks, depending on the care of the operators, and become broken from the stirring of the ore in the upper pot.

When the furnace is hot, the upper pot is charged with lump and fine ore mixed, the larger pieces about the

[1] See also M. & S. P., March 4, 1916, 'Metalliferous Mines of Hunan.'

[2] Journal of Society of Chemical Industry, London section. No. 6, Vol. XXVII, 1908; No. 10, Vol. XXXII, 1913; No. 4, Vol. XXXIII, 1914.

size of a dollar. Cheap local coal is used and the fire raised after charging. The tops of the pots are loosely covered, usually with a round cast-iron cover that collects oxide on its lower side. As soon as the temperature is high enough the ore begins to liquate, forming a pasty mass, and is frequently stirred with iron rods until it is considered to be finished, when it is in a more or less dry state. Meanwhile, when enough liquated sulphide has collected in the lower pot, it is dipped out with cast-iron spoons into molds which form brittle bricks of 16 lb. weight. The bricks are then weighed and boxed for shipment. The residue, left in the upper pot, is removed by spoons and thrown into a square iron box formed by two L-shaped castings; when cool the refuse is in a solidified lump. This refuse contains from 12 to 30% of antimony and silicious gangue, depending upon



SHOWING OPERATION OF ANTIMONY FURNACES FOR PRODUCING 'CRUDE' METAL IN CHINA.

the grade of ore and the care used in smelting. The operation requires two to four hours during which time the furnace is surrounded by fumes that are unpleasant and injurious. Since the value of the tri-oxide has become known it is occasionally collected from the flues and chimneys and sold to plants producing regulus.

The smelting is done by contract, the contractor furnishing the labor, fuel, and pots, and keeping the furnaces in repair. There are at least twice as many men employed as necessary. Prices vary with local conditions but 'crude' is usually smelted for $15 per ton. It is packed for shipment in cases bound with strap-iron and holding 224 lb. net, and about 240 lb. gross and measuring 10 by 10 by 22 inches. The cases are poorly made, and as the metal is brittle there is often loss by breakage. Cargo is usually re-packed in Changsha or Hankow and the cases bound in sacking before ocean shipment.

The smelting of 'regulus' in Hunan is on an entirely different basis from that of 'crude' smelting, as it is practically controlled by a monopoly. In 1908, C. Y. Wang[3] obtained in France for the Wah Chang Mining & Smelting Co. the rights for China for the Herrenschmidt volatilization process; furnaces were installed in Changsha by French engineers and they have since been operated by Chinese. This process converts sulphide ores into tri-oxide, which is smelted for regulus in reverberatory furnaces. The best results are obtained on low-grade ores.[4] The Wah Chang Co. also obtained from the Peking government the sole right to produce regulus in Hunan. This company owns some low-grade mines and also purchases ores. The Herrenschmidt furnaces have been erected in Yunnan near the treaty port of Mengtze by the Pao Hua Co., also connected with the Wah Chang Co. The latter produces regulus from crude, after converting it to tetra-oxide by a slow roast and also from oxide ores by direct smelting. There are at present several other plants in Hunan smelting oxide ores direct, but they all either sell their product direct or through the Wah Chang Co. This company's monopoly is contrary to the letter and spirit of various treaties with foreign powers, but so far they have succeeded in keeping their rights and have even had them extended.

The reverberatory furnaces used in smelting of oxide ores vary in size from a capacity of 300 to 1000 lb., the size holding 500 lb. being most used. They usually have a low roof sloping downward toward the chimney and a deep bed with its lowest point opposite the one working-door. The hearth sometimes consists of a square cast-iron box lined with ground fire-brick and kaolin mixed, which is put in wet and well beaten; at other times the lining is used without the iron box.

The same lining is generally re-used and is unsatisfactory, lasting from one week to two months, and an extra number of furnaces must be kept in repair to assure a constant output. The furnaces are fired with soft coal and are connected to a common chimney through flues, generally underground, that are occasionally cleaned for the condensed oxide. The oxide is mixed with soda-ash and charcoal in varying proportions, usually about 10% each. When the charge is

[3]'Antimony' by C. Y. Wang; 'Metallurgy of Non-ferrous Metals,' William Gowland.

[4]M. & S. P., July 10, 1915.

melted the furnace is cooled a little to thicken the slag, the slag is entirely removed and the molten metal skimmed clean. A 'starring' flux is then added composed of soda ash, powdered crude, a little charcoal, trioxide, and sometimes small quantities of powdered oxysulphide ores. This starring flux is varied according to the kind of material being melted and is used over again until it will no longer produce the 'star.' As soon as the flux is melted, samples are taken of the metal; when it gives a good star the refining is judged to be complete and the charge is ladled out with cast-iron spoons into molds, producing a cake 8 by 8 by 4 inches and weighing 40 lb. A little slag is put in the mold before the metal is added, and the metal is kept covered with slag. The whole operation takes from four to six hours. Oxide ores are smelted in the same manner, being broken by hand to one-quarter inch size; the charge is more frequently rabbled and the operation requires 10 to 12 hours. Regulus is boxed for shipment in boxes similar to those for crude, except slightly smaller and weighing (net) ten cases to the long ton.

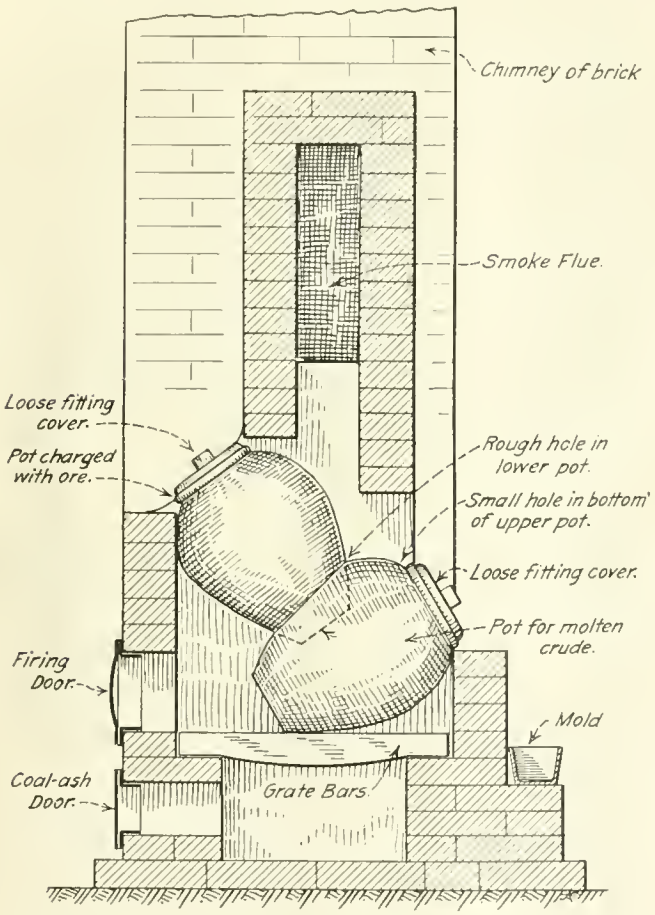
With careful manipulation the losses in smelting oxide are not over 6% and with oxide ores from 10 to 15%. Some of the loss is condensed as oxide in the flues and recovered. The star is no guarantee of purity and can be produced on 95% regulus as well as on 99%. With the naturally pure oxide ores and with the oxide from pure sulphide ores or the residue from 'crude,' the production of 99% (or better) regulus is only a matter of careful manipulation. As far as known, no one in China is producing regulus from crude or sulphide ores by the precipitation methods. The smelting of antimony refuse is being done at several plants, and with one exception the processes used are practically similar. The operation is to heat the refuse with charcoal or coke in small brick shaft-furnaces, lined with fire-brick, using a light blast and condensing the fume in chambers and scrubbing-towers. Numerous difficulties arise, the principal being the length of time required to oxidize the refuse and the difficulty in handling large charges, since the charge agglomerates, having to be constantly punched with bars. The condensers are various, but condensing seems to be the least difficulty; the best results are obtained in small furnaces with easily removable grate-bars, completely closed, and with an air-blast sufficient to oxidize the antimony and not melt the gangue, which is principally silica. These furnaces are opened and the scoria removed several times a day through the grates. Charging is done in small quantities at frequent intervals. With a high scrubbing-tower no suction is needed for the condensers. Two furnaces 9 ft. high and 3 ft. interior diameter connected to brick condensing-chambers, in all 50 ft. long, thence to a 40-ft. wooden scrubbing-tower, will handle per day three tons of refuse containing 25% of antimony. Refuse containing less than 15% antimony is hardly worth treatment. The oxide obtained is quite pure and contains from 65 to 80% antimony. Whenever the fume comes in contact with water, sulphuric acid is produced, causing trouble with pipes and tanks for the precipitating of oxide from the scrubbing-towers. One plant has a blast furnace with a capacity of 20 tons of refuse per day; it is intended to condense the fume, charge limestone and iron for flux, and produce crude metal to be refined in reverberatory furnaces. A mechanical roaster for successfully handling the refuse in larger quantities would be satisfactory. Flotation would probably produce a high-grade concentrate. However, the supply of refuse being limited and coming from many sources and the amounts remaining in the old dumps having been well collected, there is not enough supply available to warrant any extensive installation for this particularly interesting branch of the industry, and it would hardly be profitable with low market-prices. From the average quality of refuse, a ton of regulus is produced from six tons of refuse. One plant is smelting under contract to produce regulus containing 65% of the antimony contents of the refuse.

Constant careful supervision, preferably foreign supervision, is necessary to prevent theft and to obtain good results in smelting. Skilled labor with competent supervision in China is more of a problem than is generally supposed. The actual cost in making one ton of regulus by the Herrenschmidt process, including power, labor, supervision, fuel, and fluxes is not over $25. One plant quotes $35 for custom smelting of oxide ores. The actual cost of smelting oxide ores of 50% antimony, including the above items, without power, is not over $15 per ton of regulus. Depreciation, repairs to plant, and other charges vary with the size of the plant. The price of ore varies with the market price of the metal. When the price is $125 per ton, regulus can be made and sold at a profit of at least 50% and at the present prices there is a profit of from 100% to 500%, depending on how fortunate the producer has been in securing his ore. There is much room for technical improvements in all the processes, and these may come with low prices and competition.

The present scale of wages and prices for materials, with normal freights and prices, render it difficult to see how any other country can compete with China in producing 'regulus' and 'crude.' The Wah Chang Co. has an output of 15 tons of regulus per day, and several other producers bring the total for Hunan to 20 tons per day. At or near Hankow there are five plants supplied with ores from Hunan. Three plants are working on refuse, and two on oxide ores, with a combined production of 10 tons per day. The plant near Mengtze, Yunnan, was producing two tons per day in September; there is some production from Wuchow near Canton, and ores are being shipped to Japan from Canton.

Marketing. Up to the beginning of the War, the export of antimony was principally in the hands of the New Chinese Antimony Co., a branch of Cookson & Co. of England, together with French interests, and a few German firms who were interested in ores and metals besides antimony. The New Chinese company had an agreement with the Wah Chang Co. for all of their out-

put and the latter could sell only to it. Differences arose in this agreement at the beginning of the War, resulting in cancellation of the agreement, but the Wah Chang pays the New Chinese a percentage on all sales for one year and can sell to anyone. Having experienced a boom at the time of the Russo-Japanese war, the Chinese dealers were confident that another boom was coming, and the Wah Chang Co. immediately absorbed several independent producers and strengthened their political fences so that in a few months they virtually controlled the Hunan market, not only for regulus, but for crude and ore as well. Huge profits have been made that will stimulate mining in Hunan. Buyers from all sources came into existence, as nearly every foreign firm in China wanted antimony and the local prices jumped



SKETCH OF ANTIMONY FURNACE FOR PRODUCING 'CRUDE' METAL.

daily. Few of the would-be buyers knew anything about antimony and consequently there were some sad mistakes. The home brokers and buyers wanted firm offers for a few days, but the Chinese wanted cash, as the time lost in telegraphing might result in the loss of a sale on a rising market, which was often the case. Formerly regulus, crude, and ore were purchased on contract for forward deliveries with part payment in advance or in some cases full payment in long-term native drafts that could be discounted locally, so the dealer often had the cargo and had turned it for a profit before the drafts came due. With the rising market, however, matters changed completely, so that producers and native brokers often sold to the nearest cash buyer regardless of the contracts hanging over them, with the result that the foreign merchant who had contracts and had sold forward on the strength of them was left holding the bag. The result has been that, with the exception of a few reliable producers, all business is cash and there are numerous cases for settlement involving large sums in which foreign consuls are writing demands and pounding tables in vain, as there seems to be no remedy for the recovery of money advanced or cargo that should be delivered. The Wah Chang Co. opened an office in New York, where it sells its own output, and the export business has resolved into the hands of a few foreign firms. Japanese have been the largest buyers of crude as they ship to Japan and convert it into regulus for the Russian and American markets, having the advantage of their own shipping companies and financial organizations. Some ore is being produced in Japan and a little from Korea; also there is some produced from Indo-China but the bulk of the Japanese regulus is made from Chinese crude.

Since the War very little ore has been exported from China except that which was bought previously; the high freight-rates and the difficulty of getting shipping space for bulk cargo preventing ore shipments abroad. Chinese regulus suffers in the market from either lack of advertising or astute competitors, as analyses show it to be as good or better than other brands.

The table below shows the export of antimony from Changsha for 1915 to November 1, the 1914 statistics for all of China being not yet available. The ore and refuse went principally to Hankow for refining.

Antimony regulus	5,255	long tons
Crude antimony	13,502	" "
Antimony ore	743	" "
Antimony refuse	3,839	" "

ORE-STORAGE BINS at the hoisting levels in the Copper Queen mine have a measuring hopper holding one skip-load. Hoisting in balance at the maximum rate of a skip per minute, and allowing 15 sec. for tripping the hopper, each loader has 1¾ min. between times to load the hopper. In actual practice the time required to dump the 58 cu. ft. of ore into the skip and ring it up rarely exceeds 12 sec. and is frequently only 10 sec. In three shifts of one day, 3899 wet tons was hoisted, or practically 1300 tons per 8-hr. shift. Deducting 30 min. for lunch, the hoisting rate has been 1.1 skip per min. On occasion when the ore is muddy, a third man is required and only 20 or 30 skips per hour can be hoisted. Trouble is occasioned from spillage of ore, while loading into the skips, which a screen with three sides attached did not appreciably reduce so it was removed. The spilled ore averages 17 lb. per skip or 0.21% of the ore hoisted; this spill has made heavy wear on the timber in the hoisting compartments. The skips have been rebuilt from a capacity of 70 cu. ft. to 90 cu. ft. to give a margin for overload. The above notes are abstracted from a paper by G. F. G. Sherman read at the San Francisco meeting of the American Institute of Mining Engineers.

Points of View From Lake Superior

By P. B. McDonald

One-time residents of the upper peninsula of Michigan read with interest of the great snow-storm that hampered the copper production during January to the extent of 8,000,000 lb. Railroad transportation was suspended for days at a time by an old-time Lake Superior blizzard that heaped the snow in immense drifts across the tracks.

F. B. Close, who returned recently to the Copper Country after a varied experience in North and South America, is doing a good deal for the development of the Porcupine district. Besides the White Pine Extension of the Smith-Stanton interests, he is directing other explorations for Chicago and Duluth financiers.

The Cleveland-Cliffs Iron Co. continues to expand its ore business. The largest operator on the Marquette range, it is opening mines at Iron River, and has purchased 10 additional steamers for transporting ore on the lakes. Its 1916 shipments will aggregate between 3,000,000 and 4,000,000 tons. On the other hand, the Rogers-Brown companies of Buffalo are decreasing their holdings in mines and steamers by sale.

At some of the iron and copper mines it is found profitable to employ a 'drill-inspector,' perhaps a young engineer, to visit the miners underground and quietly introduce efficiency ideas while ostensibly examining the drills to see that repairs and sharpening are properly done. 'Drill-inspector' is a term better liked by the miners than 'efficiency engineer.'

Re-treatment of tailing, now a recognized economy in the Copper Country, will be extended at the mills of the Copper Range Consolidated by nearly doubling the equipment of Wilfley tables. Instead of increasing the number of Hardinge mills, these will be supplied with manganese-steel balls, which make it possible to re-grind a much larger tonnage than with flint pebbles. The Quincy is also using steel balls in its large type of re-grinding mills. The tendency to substitute manganese-steel balls for Danish and French pebbles, since the War raised the price of the pebbles, has the objection that the price of manganese steel is rising likewise.

Flotation experiments continue on copper ores, particularly from the White Pine district, where the copper is exceedingly fine. The White Pine Extension has had detailed tests made by A. J. Houle, T. G. Chapman, and J. B. Cunningham. Working with ore in which the copper was too fine to permit of the ordinary method of concentration, a recovery of 80% has been made, obtaining a concentrate of 20% copper. The Calumet & Hecla is conducting flotation tests at Lake Linden under the direction of a metallurgist from the Inspiration mine in Arizona. It is hoped to get the concentrate up to a commercial proportion of 30% copper by improvements in the methods and oils.

Isle Royale—not the mine near Houghton, but the island in Lake Superior famed for its scenery—is to be explored during the summer by T. F. Cole and associates, who have taken over the extensive mineral holdings. This island is over 40 miles long, or four times the distance between Houghton and Calumet. The Indians used to mine copper there for weapons and utensils, and attempts have been made to develop the mineral resources. It is a wild inaccessible place in winter.

James MacNaughton, in recent interviews and writings, indicated the important economies attained in the operation of the Calumet & Hecla and its subsidiaries. Among other things he said: "I expect to see the time when 13-lb. 'rock' can be made to yield a profit; at several mines during 1915 ore was mined and milled for $1 per ton. * * * The C. & H. re-crushing plant is treating 1200 to 1400 tons of tailing per day and we are getting a larger recovery of copper at a lower cost than was estimated. * * * The use of the one-man drill and Carr bit has resulted in an increased output per miner equivalent to his total production of a few years ago." Incidentally it is interesting to note that surprising increases in native silver are being met with in the deeper levels of the C. & H. conglomerate.

Just as the copper mines are striving to make 1916 a record year, so the iron mines of Michigan and Minnesota are counting on the biggest shipping season in their history. The output of iron ore to lower Lake ports is expected to total well over the record of 50,000,000 tons that was attained in 1913, and some doubt is beginning to be felt as to whether or not the carrying capacity of the lake ore-fleets will be sufficient to accommodate the extraordinary tonnage that the railroads will bring to the docks at Duluth, Superior, Two Harbors, Marquette, Escanaba, and Ashland. It is true that the iron trade is a barometer of the country's industry, and it is also true that for the past two years things were very dull on the iron ranges, so that it looked at times as though Cleveland and Pittsburg capitalists had regretted the millions of dollars put into ore mines. Now, however, the old enthusiasm and aggressiveness have returned, and great ore-trains will soon be rolling out of the range towns in number fully up to the expectations of the long-headed men who equipped and developed the mines. The shipping season will open in April.

The 30th Anniversary Reunion of old graduates and students of the Michigan College of Mines, scheduled for August 8, 9, and 10, will bring back to Houghton men from all over the World, many of whom have not met since leaving college.

The Electro-Statics of Flotation

By F. A. Fahrenwald

THE development of every new metallurgical method is accompanied by a host of contradictory statements and widely differing opinions, but it is only by the elimination and correlation of parts of recorded observations that a particular process approaches a state of perfection. The theory of flotation has called forth a number of articles, each writer applying a different hypothesis in explaining the puzzling phenomena accompanying the process.

Of the various hypotheses thus far advanced only two are based on principles of sufficiently apparent soundness to warrant serious consideration.

The first of these involves the physical surface phenomena that may produce an inter-facial tension. This has, until recently, been accredited with more importance than all the other explanations combined. The second is called the electrical theory.

The part that surface phenomena may play in linking the particles of ore to the bubble-carriers is ably outlined by O. C. Ralston, whose treatment[1] of this phase of the question includes reference to about all of the theory that has so far been found applicable to flotation. Without doubt a proper application of the laws of physical chemistry will disclose fundamental principles upon which this process may be based, and it may be in the field of colloidal chemistry that most information is to be gained.

With regard to the electrical theory, however, there has been applied a number of laws of electro-statics that, from the general nature of conditions under which flotation is carried out, would seem to be inoperative.

This hypothesis has been tolerated by Mr. Ralston,[2] it is strongly advocated by J. M. Callow,[3] while Thos. M. Bains, Jr.,[4] excludes all other theories. These three references contain the gist of all arguments advanced in support of this hypothesis, and the last of them elaborates and definitely formulates the necessary requirements for flotation by electrical means. It is my object to attempt an analysis of the various arguments advanced in support of the electrical theory, and as the only difference between this and any other theory lies in the phenomena that cause the bond between the flotative mineral and the bubble-carrier, it is understood that only this phase of the process is under discussion. It is necessary, however, in order to arrive at practical conclusions, that this question be considered under conditions similar to those encountered in practice.

Before proceeding to a discussion of the electrical theory of flotation it will be necessary to point out briefly a few of the facts of electro-statics upon which it is based.

A. The production of electricity by friction is a common phenomenon; almost any two bodies become electrified if they are rubbed together. In the case of several substances, considerable force is then necessary in order to separate them. Attraction or repulsion also occurs when an electrified body is brought near bodies that have been subjected to friction and if these are light enough (as bits of pitch, feathers, wood, paper, etc.) they may be lifted. Bodies may also become electrified by coming in contact with other bodies that already carry a charge. In this case the first body receives electricity of the same sign from the charged body and is then repelled.

B. Bodies that when electrified at one point are immediately electrified all over are called good conductors; those over which the charge diffuses slowly are poor conductors. All metals, many metallic ores, graphite, ordinary undistilled water, and aqueous solutions of salts are good conductors.

C. If a piece of metal, or other conducting material held in the hand is rubbed against a non-conductor—say, a piece of dry flannel—only the non-conductor appears afterward to be electrified. The reason is that the electrification produced on the metal spreads over the hand, arm, and body of the experimenter to the floor and walls of the room. If, however, the conductor be insulated, the degree of its electrification cannot be increased or decreased.

D. By whatever process a body is electrified there is always an equal amount of electricity of the opposite sign, which may reside upon the walls of the enclosing room or upon some other surface insulated from the conductor. Bodies carrying opposite charges, when brought in contact or connected by a conductor, become discharged. If the charges are equal they are neutralized, but if one carries more than the other the system takes on the sign of the excess charge.

E. If these bodies are strongly electrified, discharge can take place through an appreciable thickness of non-conducting material, such as air, oil, or glass. This discharge is facilitated by the presence of sharp projections upon either body.

F. (a) The space between two charged bodies is filled with lines of force that tend to move a contained body in the direction of the local lines of force leading to the surface carrying the opposite sign.

(b) These lines of force do not penetrate the surface of the conductors forming its boundaries and a hollow

conductor is electrified on its outside or inside surface only, depending upon whether the opposite charge resides upon one contained without the sphere or upon one contained within and insulated from the shell. In the latter case the entire field is contained within the inner surface of the sphere, and in the former case there is no charge within the hollow conductor.

G. The force exerted between two small charged bodies is given in the equation $F = \frac{qq^1}{d^2}$ in which q and q^1 are the charges in electro-static units carried by each of the two bodies, and d is the distance between their centres of charge.[5] If the bodies are separated by a medium other than air a factor K, known as its dielectric coefficient, must be used, and the equation becomes $F = \frac{1}{k} \cdot \frac{qq^1}{d^2}$

H. Matter itself is not acted upon by an electric force, which acts only between different quantities of electricity. When a conductor is introduced into an electric field it represents a gap or an interruption of the lines of force, resulting in an electrification of its surfaces only, that part becoming positive which is presented toward the negative boundary of the field and the reverse. In other words, the original field is divided into two. This same effect is produced in the case of a poor conductor but to an exceedingly small degree. This explains the attraction of small bodies by another that has been electrified by friction, in which case electrification by influence precedes attraction, and what is really observed is attraction between opposite electric charges.

Before considering these fundamental laws of electrostatics in connection with an explanation of flotation phenomena, it may be well to consider briefly the conditions under which different phases of this process take place.

Of first importance is the fact that all operations are carried out in conducting solutions which in every case are earthed. It is inconceivable that, after any grinding process has been applied in machines such as are commonly used, the individual positively charged particles of ore should not have come in contact with negatively charged bodies and with conducting parts of grinding and mixing machinery, even if oil has been added in a preliminary stage. The ore particles are conductors, the oil is a non-conductor, the bubbles are filled with non-conducting air, and the gangue is composed of non-conducting material.

These conditions being granted, the next step will be to apply the laws of electro-statics to criteria for flotative conditions according to the electrical theory as summarized by Mr. Bains. These include the main ideas of Mr. Callow's article and of the theory in general, so that a discussion of these in order will apply to the various other articles advancing a similar hypothesis.

1. "Ores containing valuable minerals or metals that are good conductors are the only ones that are suitable for flotation."

This seems in general to be true, but the ratio of flotative tendency to conductivity of the different ore constituents is nothing like a constant. For instance, the conductivity of galena is to the conductivity of chalcocite as 35:1. Their flotative tendencies hardly bear this ratio.

In entire opposition to this supposed requirement I found that small pieces of diamond attract a grease[6] or oil coating and attach to bubbles quite as readily as does galena.

2. "To buoy these conductors, it is necessary to supply enough electrified bubbles from below to float particles of the conductors that are attracted; hence the smaller the bubble, the better the result, the amount of gas being the same."

A bubble within a solution of various salts and acids presents a similar condition to that of the air-space within a hollow conducting sphere. It is known (see F (b) above) in this case that in order to have a charge upon this inner surface it is necessary that an opposite charge be maintained within and insulated from it. In the case of the bubble there is nothing inside to carry the charge. In case this space carried water-vapor or ionized gases, a charge could be present, but it would be dissipated quickly by diffusion of these charged particles and resulting contact with the water-surface.

If this sphere did contain charged gases and was lined with oil, there would be present the condition of the hollow conducting spheres, F (b) with enclosed charged conductor insulated from it, and carrying an opposite charge. The charges would be equal and the amount governed by the charge on the inside sphere. These charges being balanced, the bubble system could have no influence upon a body—charged or not—without the outer sphere, such as a particle of galena suspended in the water at a distance. There can be no attraction through the intervening conductor, as lines of force will not penetrate a conducting surface.

It appears evident then that, first, unless a bubble contains charged bodies (ionized gas, water-vapour, or solid) within its bounding sphere it can carry no charge; second, that unless it is lined with a dielectric the charge will be rapidly dissipated; and, third, even though a charge is present and insulated from the outer conducting sphere it can have no attraction for any body or charge without the outer sphere, through a thickness of solution.

3. "Some dielectric fluid is necessary to cover the conductor or the bubble, to prevent the dissipation of the electric charge. The thinner the film of dielectric and the greater its dielectric strength the greater the attractive force and the more permanent will be the froth."

The bubble, both insulated and otherwise, has been considered. The particle of ore, unless insulated, will

[5] The force exerted by a charged sphere acts as if originated at the centre.

[6] This fact is made use of in the recovery of diamonds at Kimberley.

be immediately discharged by coming in contact with a grounded conductor—the solution. It is immaterial whether the opposite charge is carried by the water or by some other surface, the effect will be the same. Assume, however, that the ore particle is charged, and insulated. Again we have the case of one charged conductor (the ore) being enclosed within another (the surrounding water solution) giving a system which is

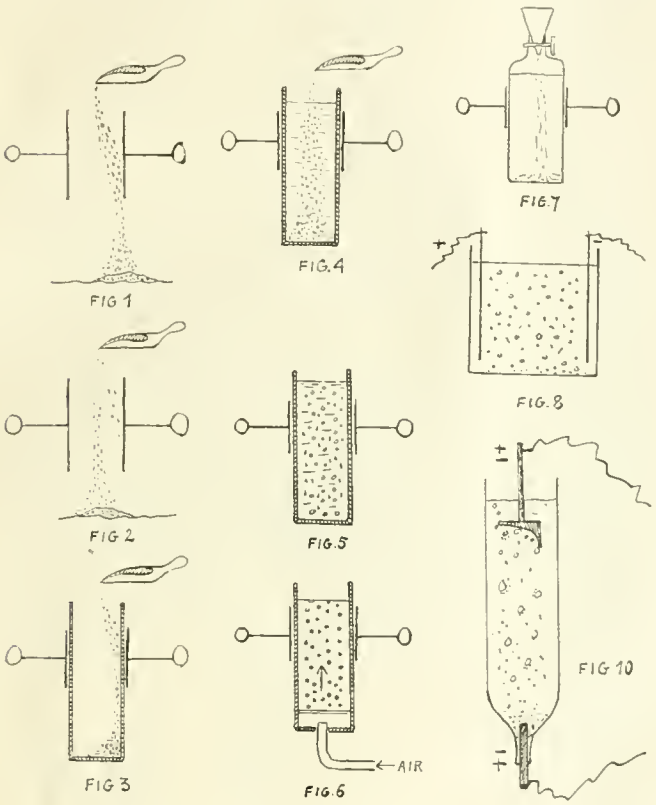

FIG. 1.

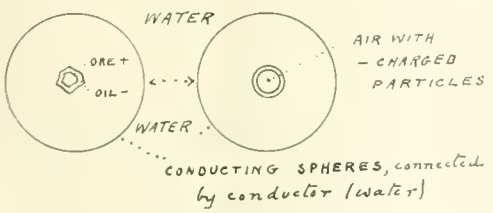

FIG. 2.

neutral with regard to any other charge or system without the outer sphere.

Under conditions electro-statically ideal these forces may be pictured as in Fig. 2. Both bodies are charged and insulated, and suspended in an intervening conducting medium. The systems ore-oil-water, and gas-oil-water, are without effect upon each other.

In case the gas is generated from the ore the particle could not be insulated unless by some phenomenon not understood at present. If the gas is air passed mechanically into the pulp it would be forced into contact with ore particles, in which case the charge carried by each would have its effect upon the other. That a mass of air containing charged vapor or gases could be insulated before coming in contact with the conducting solution is not reasonable.

Assuming, however, that both bodies are charged, so that the second part of No. 3 (above) regarding the thickness of insulation may now be considered.

It has been proved that the force exerted by a charged sphere acts as if it was concentrated at the centre. Bearing this in mind, it is evident that in the case of particles of the size with which flotation deals, a separation of their surfaces by one micron or one millimetre will produce little practical difference in the force exerted between them.

4. "Some material must be added to the water to increase its conductivity, to obtain a clean concentrate; acids in small amounts are now used."

This factor has been considered under divisions 2 and 3. The working solution is a conductor, parts of which are interposed between the various charged particles, thereby breaking all lines of force between them.

In any attempt to determine experimentally whether or not electro-static forces play any considerable part in holding the bubble and particles of ore together it is rather difficult to select tests which will give results of value. If these forces act to the exclusion of all others it is evident that they would be represented by charges of easily measurable magnitude. For example, I have separated particles of galena (uncoated with oil), that have been carried to the top of an acid solution, weighing 60 mg. (52 mg. in water). To hold a particle of this size to the surface of a bubble requires 50.9 dynes—call it 50 in round numbers. The diameter of this particle is about 2 millimetres. The bubble required to buoy this particle must displace at least 52 mg. water, or in other words its volume must be 52 mm^3. Its diameter would be about 5.2 mm. Using these figures the equation for force becomes 52 (dynes) $= \frac{QQ^1}{12.96}$ or assuming the charges to be balanced

$$Q^2 = 673.92$$
$$Q = 25.9 \text{ c. g. s. electro-static units.}$$

It is not likely that a particle of ore or a bubble of the nature given can have a charge of this magnitude, for the reason that a potential of this intensity would discharge through a very strong dielectric. Experiments have been carried out that give ratios for electro-static units, potentials, and distance through which discharge will take place in air, using brass knobs of one centimetre diameter.

Electro-static units.	Volts at discharge potential.	Distance between knobs.
16.1	4830	0.1 cm.
56.3	16890	0.5 cm.
84.7	25404	1.0 cm.

According to these figures the charge necessary to exert a force of 50 dynes in lifting a particle of galena would be so intense that it would discharge through a dielectric as strong as air at the distance by which the centres of charges are separated. Not satisfied, however, with this apparent theoretical disproval of

the electric theory I undertook a series of experiments that should serve to check the various points in the above theoretical discussion.

No. 1. Galena ore was ground in an agate mortar and poured from an agate spoon (to prevent discharge of positive electricity, if present, from ore) between two plates of an electro-static machine. The material was deflected as shown. Plates were electrified almost to discharge point. This shows that galena ground under insulating conditions carries a charge and that a particle of this nature, suspended in a non-conductor in an electro-static field, is attracted.

No. 2. Ore was ground in conducting earthed mortar and poured from earthed spoon. Deflection of only a very few particles was shown. Perhaps the deflected particles were insulated with oil or did not come in contact with earthed surface.

No. 3. Ore treated as in No. 1 and poured between glass sides of a cell. Glass was 1 mm. thick and separated by 2 cm. Potential between plates of machine was 8500 volts. Deflection as shown. This interposition of glass had very little effect.

No. 4. As in No. 3, but the cell was full of water. Used conductivity, tap, and acid water. No deflection. This indicates that particles, charged or otherwise, suspended in a conducting solution (*i. e.* inclosed within our hypothetical conducting sphere) is not affected by electro-static forces without.

No. 5. Cell contained ore and nitric acid solution to generate gas. Neither bubble rising or ore particles dropping showed deflection. Potential 10,000 volts. The conditions here duplicate those of No. 4.

No. 6. Bubbles blown through canvas into water or acid solution were not deflected. Charged bubbles flowing in one direction would produce an electric current, and even if they were charged they could not be attracted, as here again the charges are enclosed in a conducting material.

No. 7. Ore poured into cell containing gasoline. There seemed to be a slight deflection. 10,000 volts between plates. Conditions here should not differ greatly from those of No. 3. Solution may not have been sufficiently non-conducting.

No. 8. Solution placed in electrolytic cell, arranged as shown, gave no deflection of ore or bubble with conducting or non-conducting solution. Both ions and charged colloids are susceptible to this treatment and no doubt they would move easier than the larger body and so lessen the potential on the larger masses.

No. 9. The water itself was electrolyzed to furnish gas. A two-way switch gave either hydrogen or oxygen at the bottom pole, which was covered with a layer of ore. Both gases carried apparently equal amounts of ore and with equal readiness. Bubbles in either case, upon striking the upper plate, did not discharge their burden of ore, no matter what the sign of electrode.

No. 10. Set up as in No. 9, except that gas furnished by action of nitric acid on ore. Changing of sign produced no discernible effect upon bubble or ore or upon bubbles with load when coming in contact with upper electrode plate.[7]

I wish to point out the fact that this discussion and these results are to be considered only in connection with the bond between a bubble and ore particles. The conditions chosen have been ideal, in order to isolate this particular phase of the problem. Particles of appreciable mass (+200-mesh) have been used, but this permits of an electro-static consideration without interference from exaggerated surface conditions due to smaller bodies. It is possible that an ionized solution does not behave like a solid metallic conductor toward an electro-static charge, but I know of no evidence to the contrary. Very little is known regarding contacts between solid-liquid-gas phases, but it is doubtful whether charges such as accompany phases of a colloidal solution are of much influence in the case of bodies of the size herein considered. It may be found that the oil-water emulsion or the oil-films introduce the colloidal element, and no doubt many of the slimes contain colloids, in which the electric charges are of great importance. It is known that masses of sulphides, such as galena, are positive, but these same sulphides in colloidal form are negative. Metals in mass and as atoms are positive but these also as colloids are negative. This complicates considerably the electrical theory in the case of pulp containing both sand and slime. It may be interesting to call attention to the enormous increase of surface produced by subdivision, in which case phenomena that are purely superficial are greatly enhanced.

Assume edge of cube to be	Number of cubes	Surface
1 cm.	1	6 cm.
0.1 cm.	10^3	60 "
0.01 cm.	10^6	600 "
0.001 cm.	10^9	6000 "
0.0001 cm. (micron (u))	10^{12}	6 sq. metres
0.0005 cm. (size of particles in kaolin suspension)		
0.00001 = 0.1 micron	10^{18}	60 " "
0.01 micron (limit of ultra-microscopy)	10^{14}	600 " "
0.001 micron = one millimicro (mu)	10^{21}	6,000 " "
0.1 mu. = hydrogen molecule	10^{24}	60,000 " "

When it is considered that these small particles contain the energy necessary to subdivide them, whether electrical or otherwise, it is apparent that phenomena encountered throughout a range in size of particle body will not bear a direct ratio to its mass or constituent material. A consideration of this phase of the subject is, however, without the scope of this paper, which is only given to point out a few of what would appear to be misapplications of the laws of electro-statics.

FLOTATION-FEED. The crushed ore, pulp, or other mill-product that goes for treatment to the flotation plant.

[7]The writer is greatly indebted to the departments of Metallurgical Engineering and of Physics in the Case School of Applied Science for laboratory facilities and apparatus placed at his disposal in carrying out these experiments.

Pumps for Mines

PUMPING practice in mining, as discussed by Charles Legrand of Douglas, Arizona, consulting engineer for Phelps, Dodge & Co., at the San Francisco meeting of the American Institute of Mining Engineers, is characterized by the following points:

Steam seems more satisfactory than electricity where the quantity of water to be pumped is relatively great, or where the mine does not use electric power for any other purpose. As a rule, the cost of installation is greater with electric pumps than with steam-pumps, and the latter have an advantage where flow is variable, as speed and delivery are easily adjusted to varying conditions. Electric pumps, on the other hand, require less attention than steam-pumps and reduce the quantity of heat liberated—a considerable advantage in hot mines. As electrical measurements are easier to make than steam, an electric pump is likely to be kept at a higher efficiency. The latter can be operated at a lower lift than normal without appreciable loss in efficiency.

The following tables give the results of tests under running conditions on various steam and electric pumps; with the steam-pumps the water fed to the boilers was assumed as used by the pumps, the auxiliaries of the boiler-plant being run from another source of supply.

STEAM PUMPS

Test No.	Kind of pump.	Steam cylinders, Inches.	Water plunger, Inches.	Stroke, Inches.	Speed. Rev. per min.	Gal. per min. in test.	Lift, including friction.	Steam, per water hp.-hr.	Boiler pressure, in lb.
1.	Single duplex	9	8¼	10	33.0	270	120	98.0	135
2.	" "	14	8¼	10	33.0	285	111	135.0	135
3.	No. 1 exhausting in No. 2 as a compound pump	.....	...	..	...	350	120	78.0	135
4.	Triple expansion duplex	10-15½-26	8	24	14.1	278	591	61.5	122
5.	" " "	15-23-39	10	24	12.7	391	926	49.4	125

7.	" " "	18-28-47	12	24	13.0	584	1056	35.9	143
8.	" " "	18-28-47	12	24	25.7	1207	1056	27.8	142
9.	Cross-compound, fly-wheel	19-35	5⅝	36	32.4	502	1059	23.7	110
10.	Triple expansion, fly-wheel	14-26-26-26	7 5/16	36	38.0	878	652	18.0	137
11.	" " "	14-26-26-26	6⅜	36	32.0	553	883	18.0	137

ELECTRIC PUMPS

Test No.	Kind of pump.	Motor, Hp.	Water plunger, Inches.	Stroke, Inches.	Speed, Rev. per min.	Gal. per min. in test.	Lift, including friction.	Steam, based on 25 lb. per kw.-hr.
12.	Vertical triplex, double-reduction	10	4	9	35	51	475	32.7
13.	" " " "	20	4	9	37	54	1162	28.1
14.	" " " "	50	9	10	37	302	423	29.1
15.	" " " "	50	9	10	37	303	423	25.6
16.	Vertical quintuplex, single-reduction	110	4½	12	40	159	1155	23.1
17.	Horizontal " " "	250	9	18	52	1245	605	22.2

Referring to these tables, tests No. 1, 2, and 3 were taken by condensing the exhaust of the pump, weighing the condensate, and estimating the volumetric efficiency of the water-end at 90%, as the delivered water was not measured. In tests 10 and 11 on triple-expansion four-cylinder pumps with two low-pressure cylinders, steam was superheated 35° when leaving the boiler, and the pumps were tested together.

Referring to the tests of electric pumps, No. 12, 13, and 14 were on pumps immediately after starting, while test No. 15 was on the same pump as No. 14 after a two-weeks run. Test No. 16 is on a single-reduction, spur-gear pump; and No. 17 is on a single-reduction herring-bone-gear pump.

The triple-expansion direct-acting pump is fairly economical in use of steam, provided the proportion of the steam-end to the water-end is correct for the head pumped against. It is not unusual for the steam-end to be too large, considerably increasing the consumption of steam, because of the habit of mine-managers to specify a higher lift than the actual distance. If a pump is ordered with a view to a change of lift to a lower level, as the mine is deepened, it is best to order the pump for the original lift but to specify the water-end strong enough to stand the maximum pressure expected in the future. When the lift is increased, the size of a plunger can be altered at small cost to keep the correct proportions between steam and water-end.

Compound and triple-expansion fly-wheel pumps are notably economical in steam but are expensive in installation, requiring much room and good foundations. The use of them is justified when a good deal of power is required, steam is expensive, and the mine assured of long life.

The following suggestions as to the details of pumping practice and operation are given: For gritty water, outside-packed plunger-pumps are recommended; if the water is only slightly acid, chilled cast iron plungers quickly pay for their extra cost in diminished packing; with chilled plungers it is possible to use metallic packing if the water is not too gritty nor the lift too high. For vertical pumps, metallic packing is suitable for lifts up to 400 ft. For water slightly acid, cement lined pump-bodies have given satisfaction. For acid water, plungers and pump-bodies should be of acid-resisting bronze. For gritty water, it is advisable to have large sumps where water can settle, and if possible, to have two of them, so that they can be cleaned alternately. In the Old Dominion mine at Globe, mud is cleaned from a sump by employing a small air-ejector discharging into a mine-car. For high lifts with gritty water, a satisfactory pump-valve is hard to find; to reduce the balanced pressure on the valve, narrow seats are recomended making, however, high pressure on the seats when the valve is closed. On large valves for lifts of 600 to 1000 ft., leather, hard rubber, vulcanized fibre, and soft brass are used; for clear water, soft brass is preferred.

Steam-pumps are run condensing both for economy in steam and because exhaust steam should not be discharged in the mine. The choice of a surface or jet condenser depends on local conditions; the former has less moving parts and consumes less steam, but it is likely to be out of service a longer time when the tubes are cleaned.

The question of proper size of steam-line between the boilers and pumps should be given attention. Most steam-lines are too large. It is best to have a pipe that gives a drop in pressure of 5 to 10 lb. between boilers and pumps, as the reduced condensation pays for loss of pressure. With a small pipe-line, the separator at the pump should be made a separator-receiver, to steady the flow through the line.

As to electric pumps the following facts are noted: With electric plunger-pumps, the herring-bone gear permits a single reduction in gearing the motor to the pump; herring-bone is more efficient than spur gear, but requires closer adjustment of the pitch-line, so that bearings have to be made adjustable to maintain a proper distance between pinion and gear shafts. Incidentally the proper design of bearing is important.

With electric plunger-pumps the amount of water delivered can only be altered by one of three methods: varying the speed of the motor; starting and stopping the pump as required by the flow of water; or passing a portion of the water to the pump suction. The first method is easy where direct current is available, but more complicated and less efficient where A.C. motors are used. The second method can be employed with both varieties of power, but it is hard on the power-plant if the pumping load is a large proportion of the total. The third method is inefficient in the use of power, as the pump is working at full load at all times.

Centrifugal pumps have the advantage of simplicity and ease of connection to motor with no gearing. On the other hand, they are less efficient than plunger pumps, and have to be designed for exactly known conditions, being sensitive to change of motor speed or head. In a high lift centrifugal pump of moderate capacity the passages are small, the water travels at high speed and if gritty the wear upsets the proportions of the pump, and affects the efficiency. As the efficiency of electric pumps is not much affected by their size, where the flow of water is variable it is advisable to have several units, each of small capacity, so that the number of units running can be adjusted to the quantity of water pumped.

As to air-lifts, these are inexpensive to install and will handle large quantities of water in a small space, where proper submergence can be obtained. The method could not be used from the lowest level of a mine without a lot of complications, as there is no way to get the proper submergence. Although air-lifts require a good deal of air, the other running costs are almost nothing. Air-lifts were used at the Old Dominion mines at Globe during a recent emergency. Two 10-inch air-lifts, raising the water 200 ft. and 431 ft. respectively (excluding friction) taking air at 90 to 95 lb. (at the power-plant) required the following amounts of air (measured by flow-metre) at a barometric pressure of 27 in. of mercury, the submergence in each case being 190 feet.

Gal. per min.	Cu. ft. free air per min.	Cu. ft. free air per 1000 gal.	Steam consumption.
1680	1809	1080	48.7
1794	2262	1261	57.5
1122	3051	2718	57.0
1233	3395	2753	57.6

The steam consumption per water hp.-hr. is based on air-compressors requiring 38 lb. of steam per 1000 cu. ft. of free air, delivered compressed at 9 lb. gauge-pressure.

Qualitative Test for Molybdenum

In view of the rapidly increasing demand for molybdenum ores, the Colorado School of Mines at Golden is continually receiving requests from prospectors and miners for a reliable test for molybdenum. In response to such requests the following test is suggested:

Pick out carefully the supposed molybdenum mineral, grind fine, and take a quantity equal to a pea in size and put it in a glass test-tube with a speck of paper $\frac{1}{2}$ of an inch square. Add three drops of water and five drops of concentrated sulphuric acid, and boil slowly. If molybdenum is present the solution will change to a dirty green color when almost dry, and on cooling will turn a beautiful ultramarine blue. This color changes immediately on the addition of a few drops of water to a dirty gray. Care must be taken to take the pure molybdenum mineral, to boil the exact quantities specified, and to boil slowly. Tests in the laboratories of the School of Mines p[illegible] that this method gives splendid results with all moly[illegible]um minerals.

CONCENTRATES

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

BARITE (barium sulphate) is often used as a filler in rubber goods.

PUMP VALVE-SEATS badly worn can be improved by clamping a disc of sole-leather to the rubber valve.

LARGE BLASTS of rock should be done by electricity, this being safer and surer than fuses. Direct current is preferable to alternating.

GASOLINE ENGINES may be used underground for hoisting and other purposes, if the exhaust is piped to surface. If the fumes escaped into the mine, danger would result.

REVERSE BENDING, that is, where it is first bent around a sheave in one direction, and then at some other point it is passed around another sheave in the opposite direction, is one of the severest conditions that wire rope has to meet.

TRAMMING of ore underground in the proportion of 194 ft. by hand to 708 ft. by mule in one part of the Copper Queen mine cost 20.7c. per ton in 1914. All new light track was charged to this account; amounting to 47,800 ft. of drift.

TEMPERATURE of the oxy-acetylene welding or cutting flame is 3500° C. This is 1250° higher than the old oxy-hydrogen jet. The proportion of acetylene to oxygen for welding is from 1 of the former to 1.14-1.5 of the latter. The correct mixture is of great importance.

THE ZINC-VIOLET or *viola calaminaria* is a flower peculiar to the zinc mining region of Westphalia. Its yellow blossom grows on zinc-bearing soil and it is said to revert to the ordinary tricolor violet if cultivated in a garden. According to R. W. Raymond, this flower has been recognized at the Horn Silver mine in Utah.

HOISTING OF ORE at the Sacramento shaft of the Copper Queen mine in 1914, when 659,102 tons was raised, cost a total of $46,126 or 7.1c. per ton. Of this cost, $12,632 was for steam; $8712 was for engineers and oilers; $8703 was for hoist repairs; $4086 was for cage and ore-pocket repairs; and $3252 was for ropes.

LENZITE is the name given to a complex of minerals that has the curious property of detecting the aerial vibrations made by the wireless telegraph. It was found in the Waldron mine, in the Cedar Valley district, 56 miles south-west of Kingman, Arizona. The crystals are sold for $10 apiece. The name comes from Charles S. Lenz, the discoverer.

IN VENTILATED MINES there is seldom enough variation in the oxygen and carbon dioxide contents of the different atmospheres to affect sensibly the inflammability of methane-air mixtures, according to the U. S. Bureau of Mines. In mines that are not ventilated, and in sealed areas, different conditions prevail.

RIVETS have conical, button-shaped, conoidal, or countersunk heads; the other end, or point, may be either button-shaped or pan-shaped. A rivet should as nearly as possible fill its hole, so that undue stress will not be brought on its neighbor by reason of slip or play of the rivet in the hole. When driven, a rivet should be upset throughout its entire length in order that it will fill its hole. If driven hot, a rivet shrinks in cooling; however, this draws the riveted parts more firmly together. Holes are usually $\frac{1}{16}$ inch larger than the rivet and are either punched or drilled.

CONVEYOR-BELT COSTS for the transportation of ore from the shaft into railroad cars at the Copper Queen mine in 1914 were as follows:

Length of belt, feet.	Quantity carried, tons.	Cost per ton, cents.
415	1,166,734	0.122
700	1,070,363	0.242
680	984,130	0.288
60	353,621	0.087

The total cost per ton of transporting the ore from the shaft into railroad cars by belt-conveyors was 2.74 cents.

FREEZING of compressed-air pipes in winter, says Frank Richards in *Practical Engineer*, is caused not by the freezing of the air, but by part of the water in the air. The capacity of air to hold water decreases with falling temperature, as in passing through a long pipe in cold weather. This moisture collects and flows along the bottom of the pipe. Freezing of the water takes place in freezing weather, accumulating ice until the pipe is completely choked. The remedies include: burying the pipe in the ground; covering it with protective material such as manure; providing means for drawing-off the water at low points by draining; employing an after-cooler near the compressor with a good steam-separator to take care of the water, the use of which should leave little or no water in the line.

ELECTRIC PLUNGER-PUMPS have a general greater efficiency than centrifugal pumps. The following table of three pumps of each type in the mines of the Cleveland-Cliffs Iron Co., Michigan, shows the relative efficiencies:

	Head in ft.	Gal. per min.	Percentage of over-all efficiency.
Six-stage centrifugal pump	933	988	54
Four-stage centrifugal pump	409	288	51
Five-stage centrifugal pump	498	1153	57
Duplex double-acting geared plunger-pump	833	992	85
Triplex single-acting geared plunger-pump	409	304	82
Duplex double-acting geared plunger-pump	509	1406	82

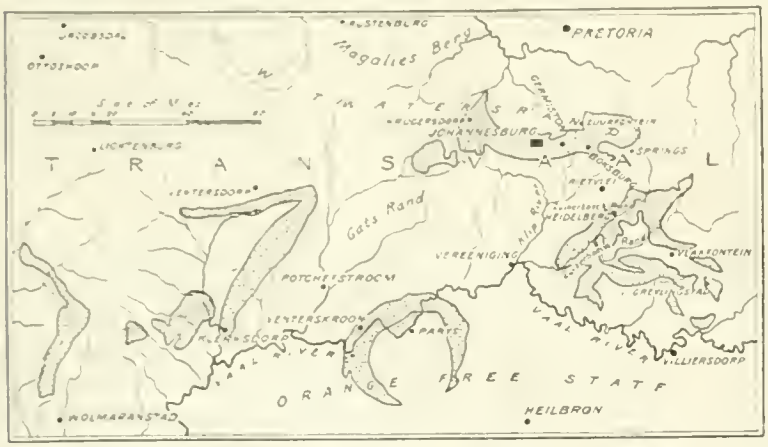
REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

LONDON

Rand Problems—Labor and Ore-Supply—Cornish Mines, Markets, and Taxes—Ore-Dressing and Glass-Tops on Concentrators.

Rand Labor Problems. The abundance of native labor resulting from the closing of African diamond mines made possible an increase in the Rand gold output in 1915, despite the number of white men who have gone to war. As the diamond mines have resumed washing, and presumably will begin underground work again in a few months, if the present demand for diamonds in the United States continues, there is likely to be, before the year is out, a shortage of native, as well as of white, labor on the Rand. It is not generally appreciated that, despite the millions of blacks, labor shortage is an almost chronic condition in Africa, not only on the Rand,



THE GOLDFIELDS OF THE TRANSVAAL.

but in the Congo. At the Katanga mines the Union Minière uses a number of small Bucyrus steam-shovels in places where natives might be expected to be employed, and does so not only because it is economical, but because there is an actual shortage of laborers. This same deficiency is one factor, along with absence of transportation and the limited supply of water, in holding back development of the tin deposits of the Congo. It is true that there are millions of blacks, but few of them are laborers. In South Africa proper, many thousands of Kaffirs have been trained to work and, so to speak, have got the habit, even if it be not firmly fixed. The tropical 'boys,' however, upon whom the industries of the Congo must rely altogether, and on whom the Rand must depend for any great expansion, have not become accustomed to work in a white man's sense, and, in the main, see no reason why they should. Their wants are simple and soon satisfied, and while men work hard and long for a piece of cloth, a tin trunk, or some other piece of property, possession of which sets them above their fellows, they have no wants that lead them to continuous labor. Perhaps some genius will meet the situation by establishing in the affections of the dusky belles of the region an African edition of the *Ladies Home Journal*, much as the Tennessee Copper Co. got steady work from its men by opening a millinery shop. Short of some such round-about campaign, it seems inevitable that Industry will develop in Africa faster than black men are trained for it. Another matter that is becoming more and more serious is the decrease in white labor on the Rand. In spite of the high wages and easy conditions new men are not coming in to take the place of those who constantly leave the mines to open small ranches or engage in other business, or, it must be sadly admitted, who fall victims to phthisis. Slowly the day is coming when the white workman on the Rand will lose his job, and the few left will be promoted to positions as bosses. These various problems related to labor therefore forbid expectation of any considerable increase in output from the Rand or even, perhaps, a continuation of the present rate of production.

Ore-Supply. There is also the problem of future ore-supply; as to that South Africans are looking with increased confidence to the East Rand. More complete knowledge of the geology of that great basin is brushing aside apparent complexities, and more recent development is showing a surprising amount of ore of grades better than had been anticipated. While not enough ore has been mined or developed to be considered an adequate sample of a basin about 25 miles in cross-section, it is worth noting that the Brakpan, Springs, Modder Deep, and Geduld show an increase in reserves, and that this increase is not due to diluting with lower grade. The Brakpan now reports 3,017,000 tons of 7.86 dwt., and the Springs has 1,125,000 of 10.4 dwt. ore. Modder and Geduld continue to be profitable, and East Rand mining is certainly coming into its own. The Daggafontein has finally been financed by the Consolidated Mines Selection, joining Henderson's Transvaal Estates, and work is to be hurried. It is significant that Consolidated Mines Selection undertakes to supply £300,000 within two years, despite the fact that flotation of public companies is forbidden at present. This is typical of recent mine financing in London. The surplus of older companies is being used to establish new concerns, and for the present the public is not invited to participate. The Consolidated Mines Selection also takes options amounting to 365,874 shares at prices slightly above par, to be exercised at intervals in the next few years. It is from the disposal of such optioned shares at a premium that the London financial houses make an important part of their profits. Additional East Rand properties wait to be financed, though the ore that is available except under Government lease is becoming limited. Cloverfield, a Neuman property, and Welgedacht of the Ochs holdings, are said to be undergoing examination with a view to exploration.

Cornwall. War conditions have brought a measure of prosperity, as well as many troubles, to Cornwall. The search for tungsten ore has lead to an increase of production, and to re-opening of several mines, though export restrictions and high freights have paralyzed the china-clay industry. The tin output has not greatly increased, as under existing conditions of labor shortage, high smelting-rates, and increasing profit-tax, there is not much inducement to extra effort. The East Pool & Agar, the mine managed by Bewick, Moreing & Co., has recently opened an orebody apparently of some size, and far richer than anything that has been worked in recent years. This emphasizes the desirability of pushing development into those veins that have never been worked at great depth, and

has greatly encouraged the whole mining fraternity of Cornwall. Unfortunately it is debatable whether it would be wise for the company to mine the ore now that it has been found. The excess profit, the mine having been in lean ground for years, would be large, and in one form or another the tax will amount to about 60% of the excess. Smelting rates also are high. The closing of the German market for Bolivian ore has led to a great accumulation of stocks at Liverpool, with a result that has been reflected in prices at the Redruth ticketings. The returning charge on tin ore is an old grievance, but it is one that shows no sign of amelioration locally.

The investigation of ore-dressing methods to be conducted under the auspices of the Institution of Mining and Metallurgy has not yet been actually begun, though a Government grant has been made, and much careful preliminary work has been done. Locally keen interest has been aroused by the efforts to substitute glass for the ordinary wooden and rubber surfaces on concentrating tables under the Morley Martin patents. The advantage is that glass, being structureless, lends itself to prepared uniform surfaces either by rolling the plates while hot or by use of the sand-blast later. The results of tests so far are contradictory, though it seems to be true that a higher-grade concentrate can be made on the glass-topped tables. How far it will be possible to control conditions so as to do this in practice remains to be seen.

JOPLIN, MISSOURI

Zinc and Lead Production.—Drainage of Peacock Mines is Started.—Cinomo Mine Sold for $125,000.—Notes.

The largest production of both zinc and lead ores in the history of the Missouri-Kansas-Oklahoma district is now being recorded, the output of blende being 8000, calamine, 1000, and lead 1200 tons per week. Normally the district produced 5000 tons of blende, and much less lead and calamine than at present. Foundries and machinery houses are pressed to their capacities to meet the demands for new concentrating plants. The pay-rolls are greater than ever before, wages being at their highest, an average of $4.50 per day. High prices for zinc and lead ores cause the great activity. Blende, at the beginning of March, is selling for $120 per ton, basis of 60% metallic zinc; calamine for $85, basis of 40% zinc, and lead ore (galena) for $90, basis of 80% lead, the highest figure in the history of the district. The Webb City-Carterville district maintains its lead in production of both zinc and lead ores. The opening of many new mines in that field has increased the production to more than 2000 tons of blende weekly. Practically every part of the district has shown a remarkable increase in production, and many that were inactive a year ago are now producing.

The biggest drainage project launched in the district this year is that undertaken by the United Zinc Cos. of Boston, owning several hundred acres of land in what is known as the Peacock camp, 7 miles north-west of Joplin, in the intersection of Spring river and Center creek. About 12 to 15 years ago this area was one of the largest producers in the Missouri-Kansas district, and for a number of years thereafter was important, but during a flood of six years ago, the high dikes that had been constructed around the mines were washed out and the drifts were flooded. One by one the large concentrating plants that had been operated in that field were removed, and the output of concentrates dwindled to nothing. Even the shallower work was given up, and the ground became flooded to the surface. The United Zinc Cos. will install three Texas pumps with a capacity of 1600 gal. per minute each. They will be driven by electricity, power being procured from the Empire District Electric Co., one of whose sub-stations is situated on the land. These pumps are to be installed in the old shafts of the S. H. & S. Mining Co., formerly operated by O. W. Sparks. Two will be placed in the mill shaft, and one in the north shaft, and the ground will be drained to a depth of 167 ft. The ore occurs in both soft and disseminated formation, the faces in places reaching almost up to surface. Applications for leases from large operators have been made to the United Zinc Cos., and there is every assurance that two or more large concentrating plants will be constructed in the near future. Extensive drilling on this ground, done within the past few months, shows good orebodies ahead of all the old workings. Simultaneous with the drainage operations the company will construct a large rock and earth dike, 1000 ft. long, extending along the east side of the land and shutting off the natural flow of water that sweeps down from Spring river, on the north, in times of flood. This dike will be 40 ft. at the base, 12 ft. high, and 10 ft. wide at the top.

Mining deals are materializing so rapidly these days, that it is hard to keep tab on all of them; hardly a week passes in which a $100,000 deal is not recorded. Smaller transactions are of almost daily occurrence. The last big deal at the time this correspondence is written is that of the Cinomo Lead & Zinc Co., to the Brennan Lead & Zinc Co., for a consideration of $125,000. Harry Lindermann was the owner of the mine which is situated on a lease of the Connor land, south of Webb City, Mo. The first prospecting on the land was done last summer. Several good drill-strikes were made, the ore being in soft ground, peculiar to that immediate district, at a depth of about 200 ft. A shaft was sunk, several drifts driven, and a good formation blocked out. At present ore prices it does not require a large tonnage of ore before $100,000 worth is sold; hence when the Cinomo company constructed a large concentrating plant there were numerous prospective buyers. The new company took charge on March 1.——On the Connor land, not far east from the Cinomo, but in a sheet-ground district instead of soft, the McDonald Mining Co., a producer of many years, sold for $175,000 cash, to Shackleford and associates.

G. Moore, W. B. Bash and others have acquired a lease of 16 acres of the Beacon Hill tract of the J. M. Leonard land at Chitwood, north-west of Joplin, and contemplate the construction of a 200-ton mill. First lease on this land is held by G. T. Fletcher. The new company has gone into old ground at a depth of 170 ft., and extended drifts ahead of the old workings toward some good drill-strikes that were made recently. The ore occurs in high disseminated faces. On another 16-acre lease of the same land, Hicks & Co. have sunk a new shaft to 140 ft., and are opening a good shoot of zinc.

WASHINGTON, D. C.

Notes on the Foster Mining Bill.

The bill to revise, amend, and codify the revised statutes of the United States relating to the location of mining claims on the public domain, has been introduced in the House by Representative Foster of Illinois, chairman of the House mines and mining committee, and has been referred to that committee for appropriate action. The bill is called H. R. 12,275, and as has been forecasted in this correspondence, is wholly temporary. It is but the basis for the codification of the mining laws of the country, as has been urged in many quarters, but by a special commission, instead of by a committee of the House, as this bill proposes. The Foster bill as now written is the present mining code with changes, all comprised in 65 pages, and in all making approximately 16,000 words. It is the plan of Mr. Foster to start work at once on the real revision and codification, and for that he has appointed a sub-committee composed of himself as chairman, and Representatives Taylor of Colorado, Hamlin of Missouri, James of Michigan, and Delegate Wickersham of Alaska. Inasmuch as Mr. Wickersham has been chiefly instrumental in persuading the mines and mining committee to set aside the bills favoring a codification of the mining laws by a special commission, and as he is opposed to any extensive change in the mining laws, the character of the eventual bill to be passed by the House may be inferred.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

Juneau

Bids were received late in February for sinking the Mexican, or Combination shaft, from 1750 to 2800 ft. The opening is 8 by 31½ ft., with five compartments. A steel head-frame will replace the old structure. The Central shaft is being sunk, its present depth is at 2500 feet.

January gold yields of the mines on Douglas island were as follows:

	Alaska Mexican.	Alaska Treadwell.	Alaska United.
Development, feet	140	448	1,269
Stamps dropping	120	540	300
Ore crushed, tons	19,775	78,677	45,395
Gold from amalgamation and cyanidation	$26,886	$126,510	$92,593
Operating expenses	26,533	103,853	74,208
Construction	1,156	3,367	8,052
Profit	.....	$21,392	$9,407
Loss	$1,071	.....	.....

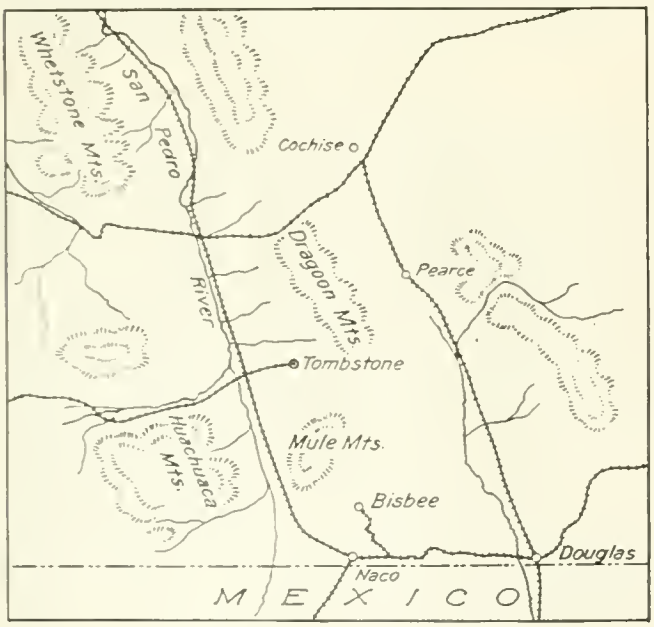
The results of operation in 1915 were as follows:

	Tons.	Output.	Profit.	Dividends.
Mexican	216,428	$ 379,797	$ 99,477	$ 90,000
Treadwell	900,211	1,828,724	859,187	650,000
United	533,419	1,042,175	367,250	252,280

ARIZONA

Cochise County

(Special Correspondence.)—A syndicate of southern Californians is developing a promising copper property in the Dragoon mountains, 40 miles north of Bisbee. Extensive outcrops have been opened by shafts and adits. The area was worked in the early 80's by men from Tombstone. Over $100,000 has been spent on development and plant. New ore-bodies have been opened on No. 5, 6, and 7 levels, and regular shipments are made. The reduction plant is to be increased to 400 tons per day.



PART OF SOUTH-EASTERN ARIZONA.

Pearce, February 23.

The Bunker Hill company at Tombstone is shipping 10 carloads of manganese ore per week to steel works in the East.

Pima County

It is reported that the American Smelting & Refining Co. has acquired the Imperial Copper Co.'s property at Silverbell 35 miles from Tucson. The mine has been closed since 1910, when the owner went bankrupt. Past records show an output of $8,000,000 in copper and silver.

In the San Xavier district, 20 miles south-west of Tucson, work has been resumed at three mines. The San Xavier zinc mine is the largest.

Yavapai County

The annual report of the United Verde Extension Mining Co. shows cash on January 10, 1916, amounting to $219,205, against $8850 on September 10, 1914. Due on shipments of ore is $290,000, of which $136,380 has been received. There is enough ore developed for a daily output up to 200 tons, averaging 10 to 12% copper, 0.025 oz. gold, and 2.21 oz. silver. The rich ore has been extracted above 1200 feet.

CALIFORNIA

Calaveras County

(Special Correspondence.)—At the Summerville mine at Fourth Crossing, formerly known as the Thorp, a vertical two-compartment shaft has been sunk to a depth of 230 ft. At 60 ft. a cross-cut was driven to the vein a distance of 20 ft.; the shaft crossed the vein at 130 ft. At 215 ft., the first working level, a cross-cut is in 70 ft., where the vein is 5 ft. wide of good value, containing considerable sulphurets. The work has all been done with air-drills. The hoist is driven by air from a motor-driven compressor. An electric hoist will soon be installed, with a 150-hp. motor.

Below the 215-ft. level, in the sump, a vein was cut, also being of good value. This will also be prospected by a cross-cut to the west from the 215-ft. level. It is planned at an early date to install an aerial tram to transport ore from this shaft to the 30-stamp mill, which is now on the property, a distance of 1500 ft. from the present shaft. A. H. Summerville is superintendent.

The Pioneer Chief Gold Mining Co. commenced work at the Pioneer Chief mine on May 30, 1915. During this time they have unwatered and cleaned-out the old workings to a depth of 240 ft. The south drift has been extended 45 ft. beyond the old workings, making a total length of 155 ft. The incline shaft has been sunk an additional 110 ft., making a total depth of 350 ft. At this point, drifts have been driven in each direction along the vein. The south drift, which is in 30 ft., shows 9 ft. assaying from $5 to $40 per ton, averaging $15. The drift north at the same level is in 35 ft. with 6 ft. of the same grade. The company is employing 23 men. Air-drills, supplied by an Ingersoll-Rand compressor are used. A 50-hp. electric motor drives the hoist. A 10-stamp mill will be installed ready for operation about August 1. Ore will be transported to the mill from the shaft, by belt-conveyor. Telephone communication from the mine to San Andreas will soon be established.

An assay-office is now being built. J. E. King is superintendent, and George Damon will have charge of the assay-office.

The Tullock Mines Co. is now unwatering the old Tullock mine and doing some prospecting in the old workings, preparatory to locating the proposed new shaft, which will be sunk a depth of 800 to 1000 ft. The work is being done under the supervision of Tom Lane, formerly superintendent of the Utica mine.

Angels Camp, February 25.

Chrome ore has been opened by C. H. McClory of Angels Camp and J. F. Bollinger of Copperopolis, near the latter place. They have bonded the property to a syndicate, and 1000 tons is to be mined.

Eldorado County

Some promising developments are reported from the northwestern part of this county, around Pilot Hill. The Bean Ridge mine has yielded $30,000 gold from pockets. The Camelback, owned by J. D. Voss, has $350,000 of copper-gold ore opened. Shipments will be started soon.

San Bernardino County

(Special Correspondence.)—A promising tungsten district is that about 6½ miles north of Goffs in the Signal mining district. It is 3 miles long and from ½ to 2 miles wide, reached by a fair wagon-road. At present there are 30 men employed and the showing is encouraging. The ore is hübnerite almost exclusively, though it is said that there are several deposits of scheelite. Work so far has been mostly trenching for float, but some development has been done in opening a few veins of promise. The ore contains from 7 to 30% tungsten, and the lower-grade ore will be concentrated if development continues as satisfactory as at present.

Goffs, February 3.

Sierra County

(Special Correspondence.)—The long cross-cut from the lower adit of the Tightner mine has cut the Osceola vein, showing fair-grade ore. The cross-cut is being extended to intersect the Red Star vein, which yielded rich quartz in the upper workings. Much work is going on in the Red Star, which is owned by the Tightner company. Good ore continues to come from the main Tightner levels and the mill is working at full capacity.

Operations have been resumed at the Gold King, on Kanaka creek, owned and managed by W. H. Weldon. It is proposed to install a small compressor and drills as soon as weather conditions permit. The property has been under development several years, and some good ore is in sight.

A compressor and other machinery will be erected at the Eastern Star as soon as the roads are in shape for transportation of heavy equipment. The mine was recently taken under bond by C. A. Jackson. Good ore has been opened.

Mining is active throughout the Alleghany field, despite deep snow at many points. The Plumbago and Oriental are working with full crews. The Louise Consolidated, Morning Glory, Twenty-One, Irelan, Mariposa, and Sixteen-to-One are busy. Rich discoveries have been recently made in the Irelan, Twenty-One, and others; that in the Irelan was made about 860 ft. in from the portal of the upper adit. A survey of this part of the mine has been made preliminary to extensive development.

Alleghany, February 26.

Tuolumne County

(Special Correspondence.)—Unwatering of the New Albany mine, near Tuolumne, which was begun several weeks ago, has been delayed by caving of the shaft. It is reported that San Francisco men will take over and operate the property, which is owned by a Cleveland, Ohio, company.

It is reported that some good ore has been found in the 300-ft. level of the Rawhide, recently acquired by the Pittsburg-Silver Peak Co., which formerly operated at Blair, Nevada. Unwatering is still in progress.

Work has been resumed at the Live Oak mine, near Soulsbyville, after an idleness of several weeks.

The Experimental mine, above Columbia, which was forced to suspend operations several weeks ago owing to collapse of a flume on the main water-supply ditch, is again active. The rich ore-shoot that was worked to a shallow depth years ago will be cut by driving the adit, now in 2600 ft., less than 200 ft. farther. Ore is now being stoped from another vein intersected by the cross-cut adit a few months ago. A two months' run on ore from this vein with the old two-stamp mill yielded $4500. The plant has lately been enlarged to five stamps.

The Springfield Tunnel & Development Co. held its annual meeting on February 12, and re-elected the following officers: president, W. M. Hall; vice-president, C. A. Belli; secretary and general manager, A. L. Horner. Joseph Cademartori will continue as superintendent.

Sonora, February 21.

Rich gravel, up to $15 per mine-car, has been opened in the If I Can mine on the Stanislaus river. The ground is in the Table Mountain channel. It is proposed to re-open the Punch Bowl mine near-by.

COLORADO

Boulder County

Last week the Vasco Tungsten Mining & Development Co. of Latrobe, Pennsylvania, shipped 25 tons of tungsten ore, worth $80,000, or $3200 per ton, the richest lot ever produced in this county.

Gilpin County

A big revival of mining is reported from the Lake, Russell, and Willis Gulch areas adjacent to Central City and Black Hawk. Companies and lessees are all busy with development and ore production.

Lake County (Leadville)

Since the U. S. R. & E. Co. started work at the Harvard shaft of the Fryer Hill project considerable improvements have taken place, and operations are attracting a great deal of attention.

At the Penrose shaft of the Down Town mines the water is down to 800 ft., leaving 75 ft. to the bottom. The flow of water is strong, but the pumps are lifting it with ease.

A company is to be formed to acquire, drain, and develop several mines in the Carbonate Hill area, near the Iron Silver property. The depth to be unwatered is 1300 feet.

Ouray County

During January the Camp Bird made a profit of $37,000 from 2534 tons of ore. During the last quarter of 1915 the mill treated 7897 tons of ore, yielding $235,451 from bullion and concentrate sold. The profit was $135,000, plus $101,000 from the Santa Gertrudis in Mexico. Development amounted to 1389 feet.

Money has been secured for the Mountain Top company's aerial tram and mill, according to the manager, G. H. Barnhart.

Teller County (Cripple Creek)

During February the district produced 77,630 tons of ore worth $1,121,515. Dividends for the first two months of 1916 totaled $195,000.

IDAHO

Shoshone County (Coeur d'Alene)

During the quarter ended December 31, 1915, the Interstate-Callahan company's profit was $721,749. There was shipped 133 tons of crude lead and 1856 tons of zinc ore. The mill treated 26,323 tons, yielding 879 tons of 55.77% lead and 20.81-oz. silver concentrate, and 12,607 tons of 48.54% zinc concentrate. The total cost was $6.11 per ton of ore mined.

The new aerial tram saved $12,000, when compared with team haulage. One dividend of $1.50 per share, equal to $697,485, was paid.

MICHIGAN

The Copper Country

To those of its 3000 employees who work through March and April the Copper Range company will pay a 20% bonus.

Copper production during February is estimated at 22,000,000 lb., 90% of normal. March should be up to the old standard, although a severe blizzard was reported on the 7th.

The Baltic company is suing the township of Adams to recover the taxes on the increased valuation of $2,200,000 put on the mine by the State Tax Commissioners.

MONTANA

Fergus County

(Special Correspondence.)—The cyanide mill at New Year in the Judith mountains will be re-started this spring, treating ore from the Gold Acres mine. The adit is in 788 ft., and work is now progressing on a drift of 325 ft. It is claimed that a large orebody has been cut by a raise of 110 ft., which will be further developed by another raise at the end of the drift. The ore is low grade, about $4 per ton, but production should prove profitable if the orebody is as large as expected.

During January bullion amounting to $7500 was produced at the new Spotted Horse mill at Maiden, besides a carload of concentrate worth $200 per ton. With the successful operation of the new mill, the output of this famous old mine is expected to greatly increase in the next few months.

At the West Kendall mine in the north Moccasin mountains an extensive deposit of white and pink gem topaz has been found. The gems occur in a solid mass, and will be cut and sold. According to James H. Conley, of the West Kendall, a 4½-ft. vein of galena, high in gold and silver, has been found during recent development. The ore is of shipping grade, and is now being sorted and sacked for shipment.

At a recent meeting of the Hanover Gypsum Co., Dan R. Brown, formerly of Spokane, was elected president. George J. Wiedeman, H. V. Alwood, O. U. Miricle, and B. E. Stack are directors. The superintendent is Frank Schultz, formerly with the gypsum mill near Great Falls. A spur-track is being built by the C. M. & St. P. railroad to the company's property near the south Moccasin mountains. Temporary houses and an office building have been erected, and machinery has been ordered. The plant will cost $100,000. Cement materials are found near-by, and a cement plant is planned for the near future.

Over a dozen townships in Meagher and Musselshell counties have been withdrawn from entry by executive order from Washington, D. C., as they are suspected of being oil bearing. The withdrawal starts in the neighborhood of Big Elk in Meagher county, and extends east and along Fish Creek basin into Musselshell county near Rothiemay and Rycgate.

Lewistown, February 21.

Lewis and Clark County

An examination of the Scratch Gravel gold mine near Helena, by four engineers, places the gross value of the ore to 200 ft. depth at $1,400,000. The vein is in granite. The 300-ft. level will be developed, the shaft sunk to 500 ft., and a mill erected.

Silverbow County

To operate the old Ophir silver-copper-zinc mine, south of the Emma at Butte, the Butte-Detroit Copper & Zinc Mining Co. has been organized in the East. Canadian people are also interested. The shaft is down 1065 ft., and will be deepened another 1000 ft. The mill will be re-modeled. W. L. Creden is in charge.

The Butte & Zenith shaft has been unwatered to 670 ft., and cross-cutting started to the vein. Another 150 hp. motor has been coupled to the hoist, and a new 1000-cu. ft. compressor installed.

At the Butte & Great Falls the shaft is down 500 ft., and cross-cutting started for the Genevieve vein, 375 ft. distant.

Considerable activity is reported from the east Butte district.

During February the Butte & Superior company produced 16,000,000 lb. of zinc in concentrate from 55,360 tons of ore.

NEVADA

Clark County

Searchlight is still producing ore, shipments in 1915 being 707 tons of ore worth $70,800, and bullion valued at $79,856. Some good developments are reported recently.

On March 25 the Yellow Pine Mining Co. will pay 10c. per share, equal to $100,000. The cash reserve is $153,000, and ore in transit $150,000. In 1915 the mine yielded 18,403 tons of ore worth $853,200 in lead, silver, and zinc. Profits were $699,611, of which $450,000 was distributed.

Esmeralda County

The estimated production of the Goldfield Consolidated company in February is as follows:

Ore mined, tons	29,400
Gross extraction	$221,000
Operating expenses	161,000
Net realization	$ 60,000

Humboldt County

The Rochester Mines Co. is to double the capacity of its mill, making 300 tons per day, at a cost of $75,000.

Nye County

Returns from Tonopah continue to drop, those for last week totaling $164,488 from 7846 tons. The Tonopah Mining Co. shipped bullion worth $56,000.

In January the Extension treated 7721 tons, yielding 178,600 oz. bullion, and $59,000 profit. The drift at 1540 ft. in the Victor ground is in a full face of rich ore.

A development of note is that at 950 ft. in the Rescue-Eula mine, where a vein of good width and value was cut. The property is south and east of the Belmont.

OREGON

Josephine County

The establishing of a mining-experiment station in Oregon, possibly at Grants Pass, is being urged in Congress by Representative Hawley.

The Queen of Bronhee mine at Waldo has been sold to John F. Twohy of the firm of Twohy Brothers, and others. The sum of $78,000 has been paid as an installment. The mine contains good copper ore, some of which is hauled 45 miles to Grants Pass, and then railed to Kennett and Tacoma smelters. The Twohy railway is to be extended to Waldo.

TEXAS

Brewster County

(Special Correspondence.)—The high price of quicksilver has led to much activity in the Terlingua cinnabar district.——The Big Bend Mining Co. is preparing to resume on a large scale, also the Marfa-Mariposa Mining Co. By installing pumps the working levels can be unwatered.——The Chisos Mining Co., which for several years has operated the principal quicksilver property in the district, has increased its output considerably recently. Workings on and below the 400-ft. level are yielding plenty of rich ore.——Many new cinnabar claims have been located in the area during the last few months, and some of these undeveloped properties will be placed on a producing basis within the next few weeks, judging by the plans made for erection of furnaces and other equip-

ment.——Engineers state that there is evidence that the quicksilver deposits extend over a large part of the border section around Terlingua, and that it is found in outcrop across the Rio Grande in Mexico.——It is reported that an

PART OF TEXAS, SHOWING QUICKSILVER AREAS.

outcrop of unusual richness was recently discovered within 60 miles of Laredo, and only about 10 miles from a railroad. W. H. Gibson of Laredo plans to develop the prospect.

Terlingua, February 22.

El Paso County

As was done at the Copper Queen smelter at Douglas, Arizona, the El Paso smelter will pay less for Mexican copper ores, to protect itself from fluctuations in the market. El Paso rates are lower than the Copper Queen, the former deducting 2c. per lb. on a 14-c. market, and a reduction of ¼c. per lb. on each 1c. rise above the 14c.; the Copper Queen deducting 2½c. on 16-c. metal.

UTAH

Summit County

During February, 11 companies at Park City shipped a total of 6564 tons of ore There are more mines, mills, and men employed than for many years. There are also a number of prospective producers.

During 1915 the Silver King Consolidated Mining Co. produced 13,719 tons of ore yielding $37.87 per ton net. The metal output was 652,076 oz. silver, 604 oz. gold, 7,843,139 lb. lead, and 411,086 lb. copper, all good increases. Dividends totaled $255,033. The surplus is $232,645.

An electric smelter is to be erected by the Daly-Judge Mining Co. near Park City. The plant will cost over $300,000 and will reduce zinc ore.

WASHINGTON

Pend Oreille County

Shipments from the molybdenite mine, owned and operated by the Molybdenite Mining & Milling Co., near Ione, were begun recently, a car of ore having been forwarded to the Henry E. Wood company, Denver, Colorado, according to Burrell J. Raines, president of the corporation, who states that consignments will be forwarded regularly every week for an indefinite period. The property is developed by several short drifts and adits in which there are five veins, from 8 to 36 in. wide.

Stevens County

In the Great Western claim of the Norman mines, near Northport, at a depth of 165 ft. the main orebody is 250 ft. long. A winze below this level is in good zinc carbonate. Ore containing 35% zinc is being shipped to Donora, Pennsylvania. Prospects generally are good.

PERSONAL

W. E. Simpson is at Haileybury, Ontario.

George E. Farish is here from New York.

Olof Wenstrom, of Boston, has gone to Mexico.

W. L. Fraser is in the Death Valley district, California.

Claude V. Haines has left London for Santa Ana, Colombia.

Edgar Rickard sailed from New York by the *Rotterdam* on March 11.

John Ballot, chairman of Minerals Separation Ltd., is in New York.

Lester W. Strauss has been visiting the Braden copper mine, in Chile.

Mark B. Kerr has returned from the Tajo mines, near Mazatlan, Mexico.

S. A. R. Skertchly, chief engineer to the San Antonio mines, has returned to Peru.

Louis Webb was in San Francisco on his way to take charge of the Lagrange mine, near Weaverville.

A. Mellick Tweedy is now connected with the South American Development Co., at Zaruma, in Ecuador.

G. M. Colvocoresses, manager for the Consolidated Arizona Smelting Co., is here from Humboldt, Arizona.

C. F. Kelley, managing director of the Anaconda Copper Co., has been to Cananea on a visit of inspection.

Derwood Copeland has finished his investigations of tin smelting in Great Britain, and sailed for New York on Feb. 18.

John B. Farish has gone to Sutter Creek, being a director of the Amador Consolidated company, which has acquired the old Eureka mine.

Charles W. Newton, general superintendent for the Consolidated Interstate Callahan Mining Co. at Wallace, Idaho, was recently at Butte.

William P. Miller has been appointed superintendent of the mines and mill of the Jacket Crown-Point Belcher Mining Co. at Gold Hill, Nevada.

E. A. Julian has opened an office in the Crocker building as representative of the exploration department of the Goldfield Consolidated Mines Company.

Roreson T. White, manager for the Caucasus Copper Co., was in San Francisco last week. He expects to sail shortly for Vladivostok on his way to Batonm.

Nelson Dickerman has resigned as general manager of the Pato Mines (Colombia), Ltd., and the Nechi Mines (Colombia), Ltd., and will return from Colombia to San Francisco, California, the latter part of April. W. A. Prichard has been appointed as his successor.

Schools and Societies

The Michigan College of Mines will celebrate its 30th anniversary on August 8, 9, and 10, by a reunion of hundreds of old graduates and one-time students gathered from all parts of the world to the college at Houghton. The committee in charge consists of: William Kelly, John W. Black, F. W. McNair, Ocha Potter, Enoch Henderson, A. J. Houle, and James Fisher. Branch clubs of M. C. M. men at the various mining centres of the Continent are assisting in the preparations.

The semi-annual meeting of the Utah Section of the A. I. M. E., took place on March 7. By the courtesy of the Utah Copper Co. and the Garfield Smelting Co., arrangements were made for members to visit the plants of these companies. The same evening a dinner for members was held at the Alta club. After the dinner was a discussion of letters and papers that have been received in regard to the part the Institute will take with reference to military preparedness. Following this a paper was read by R. F. Barker., entitled 'Preparation of Powdered Coal for Reverberatory Smelting at Garfield, Utah.'

THE METAL MARKET

METAL PRICES

San Francisco, March 8.

Antimony, cents per pound	44
Electrolytic copper, cents per pound	27.75
Molybdenum, 90% MoS_2 per pound	$1.40
Pig lead, cents per pound	6.95—7.90
Platinum soft metal, per ounce	$88
Platinum hard metal, 10% iridium, per ounce	$92
Quicksilver: per flask of 75 lb	$250
Spelter, cents per pound	22
Tin, cents per pound	43
Zinc-dust, cents per pound	30

ORE PRICES

San Francisco, March 8.

Antimony: 50% product, per unit, of 1%, or 20 lb	$2.25
Chrome: 40% and over, f.o.b. cars California, per ton	11.00
Magnesite: crude, per ton, f.o.b.	8.00
Magnesite: plastic, no iron and lime, calcined, ton	30.00
Magnesite: refractory, 11% iron, dead-burned, ton	35.00
Manganese: 50% metal, 8% silica, per ton	12.00
Tungsten, minimum 60% WO_3, per unit of 20 lb	60.00—65.00

At Boulder, Colorado, $3.30 per lb. was paid for 70.15% tungsten ore.

EASTERN METAL MARKET

(By wire from New York.)

March 9.—Copper is quiet and weak; there are few sellers of lead, and independents are getting premiums; zinc is weak with few buyers.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending	
Mch.	2	Jan. 26	57.14

June	56.43	49.03	....	Dec.	49.27	55.34	....

Although steady, the market is quiet. English, European, and Indian buying has eased. China bought a little after its New Year. A continuance of strength may be expected, but without much movement in price.

On March 2 the 'Chiyo Maru' took from San Francisco to Bombay silver worth $71,796; to Shanghai, $419,667; and to Kobe, $106,376, a total of 1,070,000 ounces.

In 1915 Ontario, mainly Cobalt, yielded 23,730,839 oz., a decrease of 1,487,155 ounces.

COPPER

Prices of electrolytic in New York, in cents per pound.

The following dividends have been declared: Calumet & Hecla, $15; Calumet & Arizona, $2; Chino, $1.25; Magma, 50c., Nevada Con., 50c.; Old Dominion, $2.50; Ray, 50c.; United Verde, 75c.; Utah Copper, $2.50; and Wolverine, $6 per share.

January returns were as follows: Chino, 5,316,975; Nevada Con., 6,157,862; Ray, 4,263,400; and Utah Copper, 11,999,910 pounds. Bad weather affected the yields. In February, Anaconda produced 23,300,000 pounds.

According to John D. Ryan the price of copper is as high as producers care to have it go. They desire the market to be on a stable basis, as they are all sold far ahead.

LEAD

Lead is quoted in cents per pound, New York delivery.

Prices for zinc ore at Joplin, Missouri, dropped $5 last week. The output of the region was 6196 tons blende, 264 tons calamine, and 1707 tons lead, averaging $102, $82, and $88 per ton, respectively. The total value was $806,738.

Butte & Superior has declared its regular quarterly dividend of 75c. per share and an extra of $10.

TIN

Prices in New York, in cents per pound.

Monthly averages.

	1914.	1915.	1916.		1914.	1915.	1916.

Tin is strong at 49 cents.

ANTIMONY

The demand is good, both for prompt shipments from the East and for spot, and quotations are strong at 44.50 to 45c. for Chinese and Japanese grades.

Eastern Metal Market

New York, March 3.

To curb speculation in metals required in the production of war materials, and the resulting high prices, Great Britain proclaimed the following drastic order on March 1: "It shall be unlawful for any person to sell or buy or to offer to sell or buy the following: iron, steel, copper, zinc, brass, antimony, nickel, tungsten, molybdenite, ferro-alloys, or any other metal specified by the Ministry of Munitions as necessary for the production of any war material unless the metal is in the possession of the seller, or in course of production for him, and, in the case of the buyer, unless the purchase is made for the actual consumers."

Reference has been made heretofore to the failure which Great Britain experienced in trying to fix the minimum price of electrolytic copper at £100 several weeks ago. At that time the Government purchased 60,000 lb. of copper which it planned to supply to munition makers at the minimum price. The London market, however, has steadily advanced and today stands at £136. As a result of the latest action, the New York Metal Exchange received no cable quotations on March 2, as the London market was closed. How the new decree will work out, and what effect it will have here is for the future to tell. It is cabled that the London metal-brokers will seek a modification of the order. They assert that it will not benefit the Government. Opinion in New York is that no good will be accomplished by the regulation so far as copper, lead, and spelter are concerned, inasmuch as the chief sources of England's supplies lie in countries beyond her control, and war conditions must govern. Spot supplies of the metals are so small in London that business there will amount to little. The London exchange may be closed, and in this event New York might easily become the metal centre of the world. The copper quotations on the London Metal Exchange have been chiefly those of standard or unrefined copper, and in this connection, John D. Ryan, president of the Anaconda Copper Mining Co. is quoted as saying: "The standard metal market in London has not been an important one for many years past. American electrolytic and Lake copper make the price the world over, and the speculation in standard copper in London has been used principally by metal-dealers to affect sentiment to depress or advance the price of stock or metal as they may be interested. The price of standard copper in London has had very little, if any, influence on the American seller of copper, and the price of copper is not and has not been for many years affected by London fluctuations to any considerable extent."

Incidentally it may be said that the copper prices quoted at the New York Metal Exchange have been for standard or unrefined metal, a fact not realized or understood by many lay publications.

COPPER

The spectacular advance in copper quotations with its attendant buying has been checked, at least temporarily, with the result that prices of prompt deliveries have eased considerably, while futures are a little lower also. The big agencies continue to restrict their sales largely to June and July metal. The quotation for these months is about 27.12c. cash, New York. Prompt copper, which was quoted a few days ago at 28.50c., can now be had at 28.12c., these prices pertaining to both Lake and electrolytic. For a week or more the market has been quiet, gradually approaching a state of dullness, a trend which started with a strike of brass-mill workers at Ansonia, Connecticut. The strike lasted only a week, the men returning to work last Monday, but the trouble was sufficient to throw over the market a damper from which it has not yet recovered. With the easier quotations came a puzzling development, not by any means a new one, yet one which surprised the trade. Despite all the talk of spot and near-by copper being scarce, these positions began to be offered freely, both by the smaller producers and by second-hands. As for the latter, it has been maintained that there was very little speculative copper in existence. Of course, it is to be considered that consumers who buy heavily not infrequently offer metal for re-sale. Electrolytic copper at London, March 1, was unchanged at £136, but on that day standard or unrefined copper declined £4 10s. to £101. Exports in February totaled 20,548 tons.

ZINC

The market here has been quiet and prices have dropped a few points, but London needs spelter and quotations there have advanced. On March 1 the London quotation was £111, establishing a new high record. Some buying on English account is expected; meanwhile the domestic market is dull. The quotation for spot-metal at New York on the 1st was 20.50c. Early positions are still declared to be scarce, although there appear to be more offerings of brass-mill special grades. These have been quoted around 22c. Second-quarter prime Western is quoted at about 18c. Producers are not pressing sales. This is a sellers' market and they can afford to wait. Exports in February totaled 3155 tons.

Sheet zinc is quoted at 25c., f.o.b. mill, 8% off for cash.

LEAD

The lead situation is a puzzling one. The A. S. & R. Co. continues to adhere to 6.30c., New York, and 6.22½c., St. Louis, and is ostensibly out of the market, yet according to reports it has accommodated some of its customers with limited quantities. The independents are well sold up, but where they do sell they are getting 6.50c., New York. Both the domestic and foreign demand is good. The supposed reason for the action of the A. S. & R. Co., in clinging to 6.30c., New York, is that it is trying to halt what may become a runaway market. Its policy is not to sell far ahead, and it has declined a great deal of business. If the independents become entirely filled up for some months to come the leading interest will then have things its own way, and this may be the plan being pursued. February exports totaled 5085 tons.

TIN

On February 28 the quotation for spot-tin advanced 5c. to 50c., but it was on bids only on the New York Metal Exchange, and no business was reported at that figure. Later on that day the bidders were offered the metal at 50c. and they declined to take it. The following day sales were made at 48c., but since that time the tendency has been downward, and the market was quiet and easy on the 2nd at 46.75c. No large business has been done for days, and prior to the 50c. bids the market was extremely dull, not so much because there were no buyers, but for the reason that sellers were cautious and unwilling to part with their holdings. It has been steadily becoming more difficult to obtain shipping licenses from Great Britain, and the brokers have dreaded not being able to fulfill their commitments. Shipments have been delayed, and should the situation become aggravated there is prospect of higher prices of which the brokers might take advantage provided they have metal on hand. The quantity of tin in this country is fair, but it is tightly held. Deliveries into consumption in February were record-breaking, amounting to 6388 tons, indicating not only that consumption is large, but that consumers are stocking-up. In stock and landing at the end of February was 1308 tons, and afloat at that time was 5866 tons. Of the deliveries in February, 1388 came to the East from Pacific ports.

COMPANY REPORTS

PORTLAND GOLD MINING CO

The report of this Cripple Creek, Colorado, company covers 1915. During the year Stratton's Independence was purchased for $325,000. To the end of 1915 the combined properties of over 250 acres had yielded $61,426,370 from 3,653,969 tons of ore. Adjacent to these workings, and on dumps there is from 12,000,000 to 15,000,000 tons of profitable low-grade ore. This will be treated on a large scale by flotation, at less cost and with higher recovery than by cyanidation. The Independence mill has been partly re-modeled for this process, and is to be enlarged to 1000 tons' daily capacity. The Victor plant is also to be changed and enlarged. That at Colorado Springs, treating high-grade ore, will continue to use cyanide. Every level of the Portland mine contributed to last year's output. Lessees only worked at 200 feet.

Development in the mines amounted to 19,808 ft., an increase of 4216 ft., each foot opening 3.6 tons of ore. Thirty-five new stopes were opened. No. 2 shaft was sunk 151 ft. to 1870 ft. depth. Indications here point to a large amount of good ore. No. 17 level has been an unusually productive one.

From the Portland mine the Colorado Springs mill treated 55,339 tons of $24.6854 ore, 213,122 tons of $3.033 ore at Victor, and 12,067 tons of $22.75 ore by lessees, a total of 280,528 tons averaging $8.151 per ton. Including the Independence there was treated 426,586 tons. The net profit was $798,460. Dividends amounted to $260,000, making $10,177,080 to date. The cash balance on January 1, 1916, was $483,503.

TEMISKAMING MINING CO.

The ninth annual report of this Cobalt, Ontario, company covers the year 1915. The general manager, F. L. Culver, states that development totaled 4763 ft., also 8853 cu. yd. of stoping. From the 400, 500, and 530-ft. levels most of the ore was extracted. Work resulted in large quantities of high-grade and mill ore being opened.

The mill treated 26,927 tons of ore, yielding 391 tons of concentrate. Silver recovered was 509,074 oz. There was 1,456,894 oz. shipped. The high-grade averaged 6413 oz., and the low-grade 1302 oz. per ton. Production cost 16c. per ounce. Silver was sold to meet current expenses, but large quantities are stored at New York and London. The year's revenue was $455,541, and expenditure $358,956. A dividend of $75,000 was paid on December 31, 1915.

The output to date is 9,116,404 ounces.

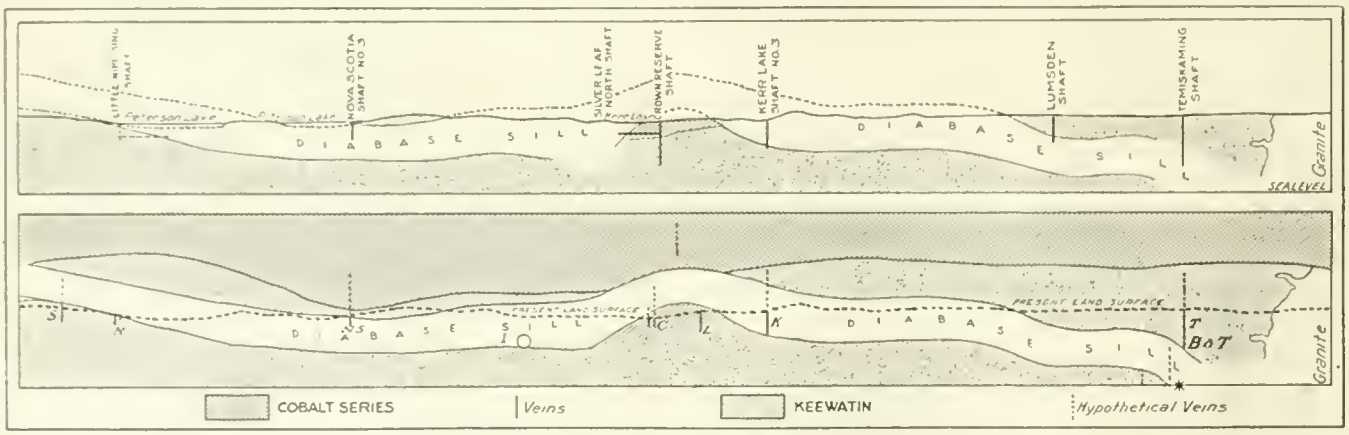
The following exploratory work is of interest, and of value to the future of Cobalt:

The Beaver Consolidated property, adjoining on the north, had driven a cross-cut 125 ft. to the west of its shaft and opened a new orebody. This discovery was made 55 ft. north of the Temiskaming line. Arrangements were made with the Beaver company to have it drive south on its property to penetrate Temiskaming ground, and in December 1914 it opened for the Temiskaming what has since been termed the "new vein system." Early in 1915, the Temiskaming started two cross-cuts to the west from the old workings in the Temiskaming, to intercept the new vein, one on the 100-ft. level and one on the 500-ft. level. Work during 1915 proved the ore-shoot on the new vein to be of large proportions and of exceptional richness.

As early as 1901, Willet G. Miller, provincial geologist of Ontario, proved beyond doubt the existence of a diabase sill which intruded both the Keewatin and Huronian formations. On the Temiskaming property, this intrusion occurs in the Keewatin as far as is known. The upper contact between the Keewatin and the Diabase has been proved to be approximately 500 ft. from the surface. Along this contact, both above and below, the Temiskaming and the Beaver have recovered their richest ores. It is reasonable to suppose that, at the lower contact or along the floor of the diabase sill, equally rich ore as occurred at the upper contact will be found. In order to ascertain the thickness of this diabase sill, a joint arrangement was made with the Beaver company to diamond-drill the properties. A drill was placed at the 900-ft. level on the Beaver, and a hole driven at an angle to penetrate both properties. It has been determined that the lower contact between the diabase and the Keewatin formations exists at a depth of approximately 1670 ft. from the surface. Having determined this, the Temiskaming is sinking the main shaft with all possible speed to cut this lower contact in the hope that like enrichments may be proved as were found on the contact above.

At other properties in the Cobalt area, it has been proved that the upper contact has been eroded away and that the lower contact is not nearly so deep as at the Temiskaming and Beaver. This was demonstrated at the No. 3 shaft on the Kerr Lake mine, where the lower contact was reached at a depth of between 274 and 322 ft. Development in this shaft, just above the contact, produced approximately 5,000,000 oz. of silver, while at the No. 2 shaft, that company got silver below the contact. Kerr Lake shaft No. 3 is about one mile north-west of the Temiskaming shaft. At the Lawson property (part of the La Rose group), which adjoins the Kerr Lake, approximately 2,500,000 oz. of silver was recovered below the contact.

The accompanying plan will explain the above notes. To the right is a long granite ridge. The lower contact from *K* down to the point designated by the start has never been



GENERALIZED VERTICAL SECTION THROUGH THE PRODUCTIVE PART OF THE COBALT, ONTARIO, AREA. THE TOP PLATE SHOWS THE GROUND AFTER EROSION, THE LOWER ONE BEFORE EROSION.

penetrated, only by the diamond-drill, which was used to explore the formation. The Beaver and Temiskaming properties adjoin, the main shafts of the two properties being about 400 ft. apart. At the point marked *B* and *T*, which would eliminate the dividing line between the properties, and just denote so much ground, at the upper contact nearly 14,000,000 oz. of silver had been removed. From *K* to the left to a point marked *O*, the lower contact has been mined by various companies and been productive of a great amount of silver. From the dip of the rock in the Keewatin and also in the diabase sill, the Temiskaming officials are led to believe that the flow came up against the granite ridge and flowed to the left, and that deposits of silver have been made between the points *K* and the star to the right. It is for this purpose that sinking the shafts on both the Beaver and Temiskaming properties to encounter the lower contact is being done.

The main shaft of the Beaver is down 1350 ft., while the Temiskaming is down 900 feet.

COPPER RANGE CO.

This company controls the Baltic, Champion, and Trimountain properties in Michigan. Results may be summarized as follows:

	1915.	1914.	1913.
Development, feet	37,903	13,542	20,353
Raises, feet	7,939	6,417	5,321
Ore stamped, tons	1,651,870	1,216,538	984,287
Average content, lb. per ton	32.5	22.9	25.24
Metal output, pounds	53,739,442	27,867,457	24,852,026
Price received, cents per lb.	17.4	13.38	14.89
Gross revenue	$9,373,120	$3,726,389	$3,707,091
Cost, cents per pound	8.06	10.66	11.71
Net income	$3,564,762	$494,600	$490,536
Dividends	1,182,003	.....	1,084,498
Surplus	2,382,759	494,600	.....
Deficit	.....	.....	593,962

Ore reserves were greater than at the beginning of the year.

Individual production was 12,028,947 lb. from the Baltic, 33,417,599 lb. from the Champion, and 8,302,896 lb. from the Trimountain. The Copper Range Co. only benefits from 50% of the Champion profit.

ST. JOSEPH LEAD CO.

During 1915 this Missouri company had the following results:

	1915.	1914.
Lead output, tons	84,356	77,404
Average price per ton	$90	$74
Net profit	$4,283,425	$2,317,040
Total income	4,392,360	2,427,686
Net income	3,489,964	1,547,275
Surplus after dividends	1,998,883	1,273,580
Previous surplus	9,416,629	8,237,190
Final surplus	11,415,512	9,416,629

The balance-sheet as of December 31 shows cash $442,127, against $392,599. The profit and loss surplus was $3,261,276, compared with $2,543,627.

IRON BLOSSOM MINING CO.

The annual report of this Provo, Utah, company contains the following data:

No. 1 workings yielded 16,549 tons, averaging 0.139 oz. gold, 25.1632 oz. silver, 2.6889% lead, and 1.1559% copper, equal to $17.7514 per ton. No. 3 workings produced 26,764 tons, assaying 0.1634 oz. gold, 31.2926 oz. silver, and 8.9212% lead, worth $23.1125 per ton. Some copper and zinc was also produced. Costs at the mine averaged $4.851 per ton; sampling, freight, and smelting cost from $8.5573 to $9.5852 per ton.

The revenue was $770,981, including $557,185 from ore sales. Dividends absorbed $300,000. The cash balance on December 1, 1915, was $128,997, a small increase.

BOOK REVIEWS

The Mining Manual for 1916. By Walter R. Skinner. P. 957. Ill., index. Published by the Author and *Financial Times*, London, 1916. For sale by the Mining and Scientific Press. Price, $6.

This is an annual volume, appearing this year as the 30th consecutive issue. It is the standard reference book of mining companies having headquarters in London, and it includes information concerning a number of American companies having shareholders in England. It is the Red Book of mining, and has won an honorably useful place as the chronicle of company finance and operations in that large part of the mining world that is irrigated by British capital. We find it invaluable in our own work, and recommend it to those having business with mining houses in London. The list of companies, directors, and secretaries is useful to anyone engaged in Anglo-American mining enterprise.

Heaton's Annual. The commercial handbook of Canada and Boards of Trade Register. Twelfth year, 1916. P. 506. Index. Published by Heaton's Agency, 32 Church street, Toronto.

As the World Almanac is to the United States, and Whitaker to England, so is Heaton's to Canada. As in previous years the annual contains official, bank, insurance, and legal directories, postal information, cable-rates, the complete customs tariff revised to date; a shippers' guide (covering every commercial town in Canada and giving the population, railways, and banks), list of registry-offices for deeds, chattel mortgages, etc., up-to-date descriptions of every town in Canada, exchange and miscellaneous tables, and a mass of valuable general information, from which cross references are given to the section 'Where to find it' (new) for the benefit of those who want further information. Mining covers 15 pages.

Metal Statistics, 1916. Ninth annual edition. Edited by C. S. J. French and B. T. V. Luty. P. 368, Published by *The American Metal Market and Daily Iron and Steel Report*. The American Metal Market Co., 81 Fulton street, New York, 1916. Can be obtained through the Mining and Scientific Press.

The publishers of this handy (4 by 6¼ in.) little book issue a daily and monthly discussing the metal markets generally, and therefore are in a position to compile a volume covering each year, this one containing all that is necessary to know regarding 1915. The chapters include notes and statistics on iron ore, coke, pig-iron, manganese, steel in all forms, copper, tin, lead, spelter, aluminum, antimony, silver, imports and exports, prices, analyses, duties, and many other factors in the metal world. A buyers' directory of 32 pages gives the full name and address of over one hundred ore and metal dealers, a useful appendix at this time of much enquiry for these products.

Details of Practical Mining. Compiled from the *Engineering and Mining Journal* by the Editorial staff. P. 544. Ill., index. McGraw-Hill Book Co., New York, 1916. For sale by the Mining and Scientific Press. Price, $5.

The journal from which this book is compiled has a department under a similar title, and in 1912 published a 372-page volume called 'Handbook of Mining Details,' culled from the same source. The new work is half as large again, and contains a great variety of material that was published between July 1912 and July 1915, all different from the first. The selection and arrangement was done by Lee O. Kellogg, until recently a member of the staff. It is impossible in a brief

review to attempt to discuss this collection of practical suggestions and results, the contributions of scores of mining men. The chapters include surface-plant and operations, timber structures, explosives, rock-drills, shafts and raises, drifting, stoping, hoisting and transportation, shaft conveyances, cars, track, drainage and ventilation, and safety and sanitation. Many opinions are expressed, but it is an excellent reference of practical work.

Materials of Construction. By G. H. Upton. P. 320. Ill., index. John Wiley & Sons, Inc., New York. For sale by the Mining and Scientific Press. Price, $2.50.

This volume is stated to be the outgrowth of a college-lecture course, but it will be of value to the practising engineer as well as to the student. It is divided into two parts. The first part deals with the determination of the properties of materials by engineering testing; tension, torsion, compression, and bending stresses are considered in order; impact and other minor tests are discussed, also special test for hardness and the fatigue of materials. Some space is also devoted to corrosion and other effects of age upon materials, and the general subject of specifications is briefly considered. Part II takes up the nature of the internal structure of materials and the control of properties through the control of their internal structure by chemical and physical means. Naturally considerable space is devoted to steel and the effects of heat treatment and of varying the proportion of carbon and other elements. The remaining chapters deal with cast iron, alloy-steels, non-ferrous metals and alloys, and cement.

Mechanical Drafting. By Charles B. Howe. P. 147. Ill., index. John Wiley & Sons, New York, 1916. For sale by the Mining and Scientific Press. Price, $1.75.

If this work were to be judged from its title alone, it might be inferred that it dealt with mechanical or machine drawing only. This, however, is not so, as it takes the student through from the beginning, including the care and selection of instruments and materials, architectural studies, mechanical studies treated as problems in orthographic projection, topographical, and development in sheet-metal work. The work is intended as a text-book for preparation schools, and as an assistance to the teacher rather than a manual of self-instruction; but the illustrations are treated in a simple manner, making it an easy interpretation for the student. Chapter II is devoted to lettering, a subject of much importance, yet here it is discussed in an abridged manner. In selecting and maintaining an efficient drafting corps for large corporations, more attention is being given to free-hand lettering, and even by small concerns. A poorly delineated drawing may be made plain and attractive by good lettering, for it is the lettering that gives character to the drawing. Orthographic projection and geometric drawing are covered in 23 pages. Chapter V is devoted to working drawings. The next one includes a number of plates for conventional details and simple machine parts. The following 31 pages deal with the architectural treatment of plans and structural details. Then comes topographical drawing. The work is concluded with perspective and shade-line drawings; the illustrations for the latter are poor and could have been treated much more forcefully.

Regulations have been issued by the Interior Department covering the manner of proving "good faith" in placer locations of phosphate lands made prior to January 11, 1915, which locations were validated by the Congressional Act of that date. Patents will be issued for such lands under the mining laws with the additional requirement that claimants must submit authenticated copies of annual "proofs of labor" showing performance of annual assessment work for each year since location, or corroborated affidavits to the same effect.

Regulations of March 31, 1915, 44 Land Decisions, 46.

INDUSTRIAL NOTES

The International Acheson Graphite Co., of Niagara Falls, New York, has changed its name and hereafter will be known as Acheson Graphite Co.

The Granby Mining & Smelting Co., of St. Louis, Missouri, announces the appointment of Alfred W. Dodd as its Eastern sales agent with offices at 165 Broadway, New York.

The manager of The Independence Gold Mines Co., L. S. Robe of Seattle, Wash., operating near Knik, Alaska, has given the Denver Quartz Mill & Crusher Co., Denver, Colorado, an order for ore-milling equipment including one No. 2 Denver quartz mill, one 8 by 12-in. Denver steel crusher, one No. 2 Denver ore-feeder and two 5-t by 96-in. copper-plates. The stamps and crusher now in use will be discarded.

A new catalogue has just been issued by the Redwood Manufacturers Co., San Francisco, which embodies a quantity of excellent information on wood pipe. Besides the data generally found in a booklet of this nature, tables are given showing allowable curvature in pipe construction, relative capacities, water-wheel requirements as for cubic feet per horsepower, pump speeds and capacities, friction losses, rate of flow for various sizes of pipe, and other tables.

The Wah Chang Mining & Smelting Co. of China and New York, states that on March 2 the antimony market was firm with a strong undertone. There are many inquiries, but for some days buyers have held aloof in the expectation of a change in price. It appears, however, that in view of the recent rise in freight from China to New York the price is going to be directly affected by a further rise. The spot market is bare, and prices vary between 43 to 44½c. per lb. The company is sold out for February shipment, with very little March offering. They quote on the 2nd for March-April shipment from China 34c., c.i.f. in bond.

A section of one of the largest cables in the world, made under a new design at the plant of the John A. Roebling's Sons Co., was tested at Lehigh University, and withstood a pull of 746,000 lb. The test took place in the Fritz engineering laboratory, under the direction of the Lehigh civil engineering department. The 800,000-lb. Richie machine of the University was used. The new cable is confidently expected to have great wearing quality, because of its design, which includes six strands of 37 wires and an independent wire-rope centre. The cable was designed for use in the Mayaria mines in Cuba, owned by the Spanish-American Iron Co., a subsidiary of the Pennsylvania Steel Co. It will be attached to 50-ton ore-cars operating on an incline-plane of more than a mile, with a grade of 25%.

The following interesting note is from the Hardinge Conical Mill Co. of New York: An installation which pleased the firm was an 8-ft. standard Hardinge ball-mill taking stamp-feed at the Dome mine, Porcupine, and reducing it for tube-mill grinding. This mill was guaranteed to give a capacity of 350 tons, and the estimated horse-power 125, with the provision that the over-size should be returned to the head of the mill. It was found that the over-size arrangement had been operated two or three days, but was out of commission when Mr. Hardinge arrived, owing to the fact that it was not needed. The mill was putting through 550 tons, taking between 105 and 110 hp., and grinding same so that it would pass to the tube-mills without classification. The company recently shipped two 8-ft. ball-mills to the Nevada Consolidated Copper Co. for fine grinding, and now has an order from them, without knowing the results of the first two, for two more 8-ft. mills.

EDITORIAL

T. A. RICKARD, Editor

BILLS have been introduced in both houses of Congress providing for the erection and maintenance of monuments marking the site or guide-posts indicating the direction of water-holes in the Western deserts. It is also proposed to issue maps and other information concerning sources of potable water in the arid regions. A sum of $10,000 has been asked for this purpose. If done conscientiously, it were well done.

BIBLIOGRAPHIES are useful, particularly when they are timely. We welcome the bibliography of concentration by flotation just issued in the form of a bulletin by the Missouri School of Mines. This furnishes what appears to be a sufficiently exhaustive list of the articles on the subject appearing in the technical press during the last 15 years, including January 1916. It also gives a chronological summary of the British and American patents relating to flotation. In short, it is a useful and enterprising piece of work on the part of the librarian at Rolla, Mr. Jesse Cunningham.

FLOTATION of oxidized ore has been successfully effected by Mr. Joseph T. Terry, Jr., at Superior, Arizona. He has been investigating the problem for the past two years, experimenting on the oxidized ores of the Magma mine. It can be stated definitely that malachite and azurite ore can be treated with high extractions and that the addition of a particular liquid to the flotation cell is helpful to sulphide flotation also. We understand that Mr. Terry does not purpose to patent his discovery, believing that he can make more money by the sale of his secret than by disclosing his method in a patent.

THE Canadian Mining Institute bulletin for March contains an interesting note by Mr. J. B. Tyrrell on the representation of the mining industry in the Dominion Parliament. This is apropos of a resolution passed some time ago by the Canadian Institute asking the Government to endeavor to get some mining engineers, or men otherwise familiar with the mining industry, into one or other of the two legislative chambers in order that they might give useful advice in regard to measures designed to aid one of the basic industries of the country. The Canadian cabinet consists of 17 men, of whom 9 are lawyers. In England the legal profession is even more strongly in possession of the administration, as is emphasized by Mr. H. G. Wells in a recent article in the *Saturday Evening Post*, in which he argues that one of the beneficent results of the War will be to get rid of an excess of lawyers and their medieval methods in the control of national affairs. Mr. Tyrrell advocates the larger employment of engineers in an advisory capacity to his Government during this time of war and he reiterates the request that mining affairs at Ottawa be regulated and assisted by utilizing the experience of mining engineers. His suggestion is not without application to Washington.

CRUSHING, that is, the mechanics of the operation, is a subject of practical importance. Last week we published a letter from Mr. A. O. Gates, and in this issue Mr. H. Stadler returns to the charge. He is a vigorous but withal a genial disputant. As a matter of fact he might be forgiven if a little acerbity were apparent in his discussion of the subject, for he seems to have received rather shabby treatment from the Mines Trials Committee at Johannesburg. A committee is apt to be less kind and less considerate than any one of its personnel. Not only was he compensated for his sincere technical efforts by a miserable remuneration, but the Committee forbade him from using his own data in any published writings. To pay an engineer no better than a roustabout is—shall we say—unprofessional on the part of a committee of professional men, but to place an embargo on useful knowledge is worse. Every member of the profession ought to be a unit in condemning secrecy when unnecessary.

IN our issue of March 4 we discussed Chinese mining regulations. Since then we have received word from Peking that Mr. G. G. S. Lindsey, who has been in China for the past twelve months in connection with the grant of a mining concession to a group of European capitalists, headed by the Central Mining & Investment Corporation, formerly identified with the firm of Wernher, Beit & Co., has finished his task. On the completion of it an Imperial mandate announces that Mr. Lindsey has been asked to undertake the work of drafting a new set of mining laws and regulations for China. We are informed that he has accepted the appointment. As we explained to our readers recently, the Chinese government has made several attempts, dating from 1902, to promulgate mining regulations satisfactory to the treaty powers, but so far every attempt has proved abortive. Now, in fulfillment of its earnest desire to carry out existing obligations and to induce foreign capitalists to aid in the development of the country, the Imperial Government at Peking has made a new departure. It is expected that the regulations to be drafted by Mr. Lindsey and his staff will be prepared in accordance with modern mining requirements, and on a liberal basis,

with the object of opening the mineral resources of China to foreign enterprise. We need only add, for the few who may not know who Mr. Lindsey is, that he is a Toronto lawyer, well and honorably known in Canada, especially among those engaged in mining, as is proved by the fact that in 1914 and 1915 he was president of the Canadian Mining Institute; he is fully fitted, by his knowledge of mining and of law, by his energy and tact, to perform well the difficult task entrusted to him.

EARTH TREMORS on the Rand had become so frequent and so perturbing to the local community that the Union Government of South Africa appointed a commission to investigate the matter. This commission has now issued a report stating that the shocks originate from mining operations, and not from earthquakes proper. They are due to crushing of the rock-pillars left in the big stopes of the deeper mines, such crushing and collapse of ground being due to the superincumbent weight, which is increasing steadily as the ore is excavated over larger areas underground. The tremors caused by the shock are transmitted to the surface and for a distance of as much as seven miles. The greater frequency and violence of the tremors at Johannesburg, as compared with other towns along the lode, is due to the more intensive mining in that neighborhood. Of course, little of this is new to those well informed, but the publication of it in the Transvaal may serve to allay public anxiety. 'Air-blasts' are fairly well understood in other districts where the deep mining of lodes of relatively flat dip is extensive, as at Hancock, in Michigan, and in the Kolar district of India. The Commission suggests that the shocks may be prevented by the removal of existing pillars when insufficiently strong and the adoption of sand-filling in substitution. Also, new shafts should be protected by larger pillars, and both the inclines and the drifts should be excavated in the foot-wall rock. Some of this has the savor of a counsel of perfection; we shall be curious to see how nearly the advice is followed.

Is it Intervention?

On March 9 the tawdry melodrama of Mexican misrule suddenly diverted attention from the heroic struggle at Verdun, and our daily press enjoyed an orgy of irresponsible sensationalism. Obviously the action of Pancho Villa in crossing the border to make an unprovoked attack on the little town of Columbus, in New Mexico, was not merely a brutal folly. As an expression of hate, it would have been stupid, for while the Mexican bandits killed 16 persons, of whom half were civilians, they themselves lost, in the attack and retreat, at least five times as many. The purpose of the raid was not punitive, but political. Villa has been playing a losing game in Mexico; as a revolutionary he has lost; unable to obtain a following against Carranza, he plans by this desperate act to involve Mexico in war with the United States and pose again as a national leader. The intolerable outrage of a massacre of Americans on American soil would arouse reprisals, he argued; it would compel the government at Washington to abandon 'watchful waiting'; it would compel President Wilson to send troops across the line. That would give Villa the chance to rally the Mexican people against the invader; instead of being a beaten rebel, he would spring into the limelight as a patriotic chieftain. He has nothing to lose and all to gain by creating complications between the Mexican and American governments. It is possible that his expectations may be fulfilled. Our yellow press talks recklessly about "invasion" and the sending of a "big army" into Mexico, instead of recognizing that the immediate purpose is only to capture an international outlaw. Mr. Hearst assures the President that he and his papers will "stand by him [the President] loyally" now that he has decided "to avenge the insults and outrages inflicted upon Americans." That is exactly the talk Villa hoped to hear. Meanwhile Carranza is in a quandary. He is between the devil and the deep sea—between Villa and Washington; if he acquiesces in American pursuit of the bandits into Mexico, he will give Villa the opportunity to dub him a traitor; if he refuses, he will face American intervention and be driven by Mexican sentiment into joining with Villa, Zapata, and all his former opponents into a defensive war against the gringo. On the 10th inst. he sent a message from Guadalajara asking for permission to send troops across the border, asserting that "the tenacious pursuit" by some of his men under General Luis Gutierrez had been the cause of Villa's incursion into American territory. If so, why did Gutierrez fail to arrest Villa on his return? In transmitting this diplomatic request General Carranza referred to the agreement made thirty years ago between the American and Mexican governments whereby each allowed the armed forces of the other to cross the boundary in pursuit of the Apaches, who were then on the rampage. But the head of the Mexican government made no reference to the American preparations for sending an expeditionary force against Villa. On the 12th inst. he published a manifesto in Mexico City stating that under no circumstances would his government sanction the invasion of Mexican territory by an armed force from the United States "without reciprocal rights being granted to the Mexicans." On the 13th the Government of the United States granted permission "for military forces of the *de facto* government of Mexico to cross the international boundary in pursuit of lawless bands of armed men, who have entered Mexico from the United States, committed outrages on Mexican soil and fled into the United States," this being an exact description of Villa's performance, *mutatis mutandis*. But the above permission is granted on the understanding that the *de facto* government of Mexico grants the reciprocal privilege, and the United States assumes "that, in view of this agreement, the arrangement is now complete and in force," so that American cavalry will be in Mexico before our readers see these remarks. But before these words get

into print, and while these diplomatic exchanges are in progress, Villa is distancing his pursuers and planning fresh depredations likely to arouse the people on both sides of the border to mutual antagonism. If the American cavalry could have caught or killed him in the pursuit immediately after the raid, it would have been easy to apologize to the Mexican government for transgressing its territory; or if Carranza had promptly offered to contribute a Mexican force equal to that organized later by General Funston for the purpose of putting an end to Villa's depredations, it would have removed several opportunities for friction. Now the matter, it seems to us, is largely out of the hands of either government; the course of events depends on Villa's actions. If he massacres an American community in Mexico or does anything else outrageously to flout American sentiment, it will be impossible for President Wilson to withstand the popular demand for military operations on a large scale; it may be equally impossible for President Carranza to avoid calling his people to arms in defence of their country. Thus the Mexican revolution may find its sequel at last in American intervention.

Flotation of Chalcocite Ore

In a recent issue we stated that the man who first proved that copper in the form of chalcocite could be concentrated by frothing deserved grateful remembrance. Since then we have ascertained the facts in the case, and desire hereby to promote a grateful remembrance of those deserving of the credit. On December 6, 1911, Mr. Edward H. Nutter, the representative of the Minerals Separation company in San Francisco, received a sample of chalcocite ore from the dump of the Joe Bush mine, belonging to the Inspiration Consolidated Copper Company, at Miami, Arizona. That sample was sent to Mr. Nutter by Mr. I. W. Greninger, then in the employ of Minerals Separation, but now underground superintendent for the Inspiration. The sample was tested by Mr. E. W. Wilkinson in the Minerals Separation laboratory, in the Merchants Exchange building, San Francisco. The result was a 9% concentrate and a 0.4% tailing on a 1.4% copper ore. Rather better results were obtained subsequently on some samples from the Miami mine, but still they were not good enough, it being recognized that they were due largely to a gangue-supported froth that could not be reproduced in practice. So nothing more was done until November 1912, when another series of tests was made on Inspiration ore, using the slide machine. On a 2% ore, a 15% concentrate was obtained with an 87% recovery, and a 39% concentrate with a 55% recovery. The various tailings assayed from 0.11 to 0.20% copper. These tests were made by Mr. F. A. Beauchamp in the same laboratory. A telegram stating that a 15% concentrate could be obtained with an 87% recovery was mutilated on its way to New York and on arrival was made to state that a 50, not 15, per cent concentrate could be obtained. The higher figure caused considerable elation to all concerned, notably Dr. S. Gregory of Minerals Separation and Mr. W. D. Thornton of the Inspiration company. However, Mr. Nutter and his staff felt warranted in promising good results and forthwith made arrangements for the erection of an experimental plant at the mine. By March 1913 it was possible to give decisive results. These showed a 35 to 40% concentrate with a 90 to 92% recovery on a 2% chalcocite ore, leaving tailings assaying from 0.15 to 0.20% copper. Satisfactory results were obtained even when the air in the mill was so cold that the bubbles froze before they were out of the flotation-cell. Some difficulty was caused by ore having a granitic matrix in which a decomposition product, or kaolinized mineral, was present. This being of a colloidal nature, led to the diversion of the oil from its proper function. Final success ensued when Mr. G. A. Chapman suggested the addition of oil to the pebble-mill, whereby the mineral particles became oiled at the moment of exposing fresh fractures. This idea was patented promptly by Mr. Chapman for Minerals Separation. It remains to state that the tests were supervised by Mr. Louis R. Wallace, now superintendent for the International Smelting Company at Miami, the evidence then obtained warranting a reasonable expectation that on a 1.58% ore, there would be obtained a 27½% concentrate with a recovery of 92% and a tailing loss of 0.13%. This has been measurably fulfilled, for if the extraction now is only 83% it is because a small proportion of oxidized ore is allowed to go to the mill with the sulphide product. This then is the story of how chalcocite ore was first treated by flotation. It does credit to the Minerals Separation staff, for it is owing to their insistence that the Inspiration company put the question to a test and finally erected a plant of 15,000 tons daily capacity.

After the War—I

If popular expectation could determine the length of the War, we should know when the howitzers would cease from troubling and the trenches be at rest. By general consent it is assumed that hostilities will continue during the current year, but that they will be ended early in 1917. Everybody seems agreed to brush aside the nightmare thought of a persistence of this organized calamity into future years. On that basis it is possible to discuss the effects of the War; without some such assumption of its length it is futile to try to make any sort of forecast. Obviously if the nations are to fight until one side is crushed, invaded, and devastated, then all the current ideas concerning the trend of industry in this country are childish. Should either the Central powers or the Entente nations be conquered, destroyed, or disintegrated, then the United States would certainly suffer keenly from the cataclysm. We do not believe that such will be the result, nor do others better in-

formed. On the contrary, it seems likely that as national industrial organisms all the existing countries will survive, although changed as to boundaries and suzerainties in regard to some parts of them. We accept the idea that the War will last not more than twelve months or thereabouts. If so, what then will be the effect? No so catastrophic in a material way as is suggested by many authoritative writers; more calamitous in a psychical sense than is assumed by many thoughtless ones. It is a characteristic of the English-speaking people that they take it for granted that eminence in any one field of human activity fits a man to express an authoritative opinion on every other subject. Mr. Ford and Dr. Jordan are quoted continually on subjects not even remotely connected with motor-cars or fishes; the opinions of Mr. Hall Caine or Mr. Kipling on the War and its many political complications are more seriously regarded than those of Mr. Hirst of *The Economist* or Dr. Dillon of the *Daily Telegraph*. For this a sensational daily press is largely responsible. Yet the observant reader has been offered many thoughtful treatments of the all-pervading subject by competent observers. From them he may conclude that the scaremonger, as usual, has been more noisy than intelligent. The actual loss of life as yet has been far less, in proportion to population, than it was in the American Civil War; and even if the fighting in Europe lasts for another twelve months, it is unlikely to reach the 2½% of fatalities in the North, much less the 4% of loss to the Confederacy. As regards the destruction of capital, it is probable that the wastage of natural resources has been exaggerated even in Belgium and Serbia, for example, and that the natural productivity of these regions, as of other areas occupied by embattled armies, will be restored not long after peace is declared. We read already of the growing grain that hides alike the graves of the invader and the defender on the battlefield of the Marne. In an excellent article in *Collier's* Mr. Henry C. Emery quotes John Stuart Mill in support of his contention that a rapid recovery from the effects of war is in accord with the theory that the destruction of wealth incidental to warfare is different in kind rather than in amount from consumption during peace. Sacrifice of comfort and compulsory thrift during war-time go far to offset the obvious financial losses, and the good habits learned under stress survive in such measure as to become a source of economic strength to a nation, which, on the declaration of peace, is able to widen the margin between maximum production and minimum consumption. Hence the extraordinary recovery made by France after the war of 1870 and of Russia after that of 1904. The Civil War affords an even better example, for it illustrates two phases: The South did not recover for years because its labor-supply collapsed when the slaves were freed. The North continued the industrial development that the War had only checked, for this country was then on the eve of a great expansion, due to the exploitation of natural resources that had barely been tapped. We need not foresee a collapse of labor in Europe, but we may anticipate a better organization of that industrial weapon, including a more intelligent use of women in certain kinds of work for which they are naturally fitted. Ideas of general bankruptcy may be disregarded. As Mr. J. Laurence Laughlin shows, in *The Annalist*, the War has not destroyed the store of gold in the countries likely to trade with us; on the contrary, France, England, and Germany have increased the absolute amount of gold held in reserve by their central banks. Even those countries now burdened with excessive issues of depreciated paper will be able to redeem their obligations in gold. While we have been bemused by the stupendous cost of the War and the bigness of the sums raised by the belligerents, it is likely that most of us have forgotten or been otherwise unaware of the latent wealth of the great nations involved. As Mr. W. E. Chancellor suggests, what is a hundred billions of dollars when compared with the resources of the earth, the whole of which is now directly or indirectly contributory to the expense of Armageddon? A hundred billion dollars is stupefying until we recall the fact that a billion people on 30 million square miles are engaged in activities that are being taxed for the purpose of supplying that hundred billion dollars. The wealth of the British empire is at least 250 billions, that of the United States 215 billions, and that of Russia, Germany, and France from 70 to 85 billions apiece. The national incomes of Great Britain, Russia, France, and Germany range from 22 to 30 billions per annum. The six great powers have national incomes aggregating 140 billions per annum, while the total revenue of civilized beings does not fall short of 200 billions per twelve months. The annual saving in countries like England or Germany is over two billion dollars. Thus a possible charge of five billions in annual interest, among the six great belligerents, need not provoke either insolvency or revolution. Hence we come to the conclusion that neither in men nor money will Europe be so crippled as to cause a commercial collapse of world-wide consequence.

In our next issue we shall discuss the question as it applies more directly to American industry, especially mining. Yet we cannot forbear from adding to this postscript. We have emphasized the material loss, because that was our immediate subject, but the man is ignorant indeed who does not realize that the vast and futile brutality of this war has caused the world a loss greater than any number of billions in money or even many millions in lives. To the young it is a great spectacle; a heroic struggle; a moving picture of transcendent interest. To the older generation it means the stultification of Christianity, the sending of civilization to the shambles, a satire on human intelligence. The imponderable results and the spiritual consequences will send their perturbations to every shore of the seven seas and penetrate the tidal waters of human thought to the uttermost corners of the earth. We, or our sons, shall outgrow it, let us hope, for the world is young and life an epic, but it takes all the optimism of youth to repel the horror of the times.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

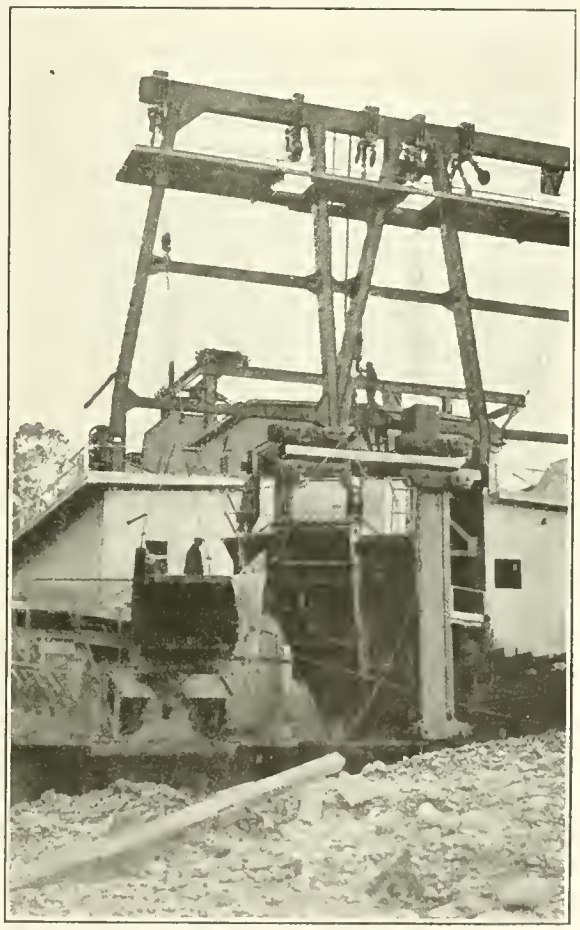
Natomas and Re-Soiling

The Editor:

Sir—A recent visit to Folsom enables me to contribute some notes on the working of the new dredge of the Natomas Consolidated, with particular reference to the re-soiling of the ground after the gravel has been dug and washed for its gold contents. In designing a gold dredge that will leave the ground in such a condition that orchards at least are practicable, two limitations must always be kept in view: first, that the efficiency of the gold saving be not impaired, and, second, that there be no material increase in the cost. Experience with the Natoma No. 4 dredge operating on the American river indicates that with some changes, already designed by the management, both conditions can be fulfilled. Their importance can be appreciated by considering that even with ground only 27 ft. deep an increase in the working cost of only one-quarter of a cent per yard would mean that over $100 per acre would have to be charged to reclaiming the land, a value on which farmers in California often fail to earn interest even where the land is good. Changes now being made in the reclamation feature of Natoma No. 4 bring out another point, namely, that notwithstanding the ability and long experience of the management in gold-dredging, results are not obtained except by actual trial of proposed devices, for as with dredging generally, progress has come about by working on an empirical basis.

The only substantial difference between the ordinary type and Natoma No. 4 is that two stackers and double-deck sluices are used, all four being mounted on swivels. A small monitor is also mounted on the stern of the boat to level the tailing. If the other devices are working properly there should be little or no need for the latter. The principal difficulty appears to be that the quantity of material discharged by the revolving screen onto the stacker-belts is such that it heaps to a height not permitting its being covered by fine from the sluices. Much of the fine material may be seen running off the tailing-piles back into the pond to be covered by coarser material, the reverse of the desired result. The management is confident that this may be remedied by installing a grizzly with five-inch openings at the end of the revolving screen, so as to deflect boulders through two or more chutes to the bottom of the pond. It may be noted here that the detail of design and procedure necessarily depends on the character of the ground to be treated. Plainly, if the original amount of soil be too scanty the problem may be insoluble. A considerable proportion is usually carried in solution by the pond-water. Uneven contour of both bedrock and surface, particularly the latter, also greatly complicates matters. In the case of a deep hole immediately following a shallow area a large quantity of material from the stacker tends to pile up on high bedrock.

Other changes of less importance are planned, such as



NATOMA NO. 4 DREDGE.

the lengthening of both stacks and sluices by 10 ft. The best position for the sluices, according to the management, has been demonstrated to be directly in line with the boat; consequently, swivels are not needed. The swinging of the boat and consequent swing of the sluices brings about sufficient distribution. The height of the upper tumbler-shaft above the water-line, namely 30 ft., permits the placing of a grizzly. In case of No. 1 dredge now being re-built, 32 ft. has been allowed, thereby ensuring ample headroom.

A comparison of dredged ground on both sides of the

main Folsom road indicates the amount of progress already made. Instead of huge irregular piles, a fairly level pile of tailing is the result of the present working of No. 4 dredge. The dredging industry owes a debt to the Natomas management for its well considered efforts to solve the reclamation problem.

Patents

The Editor:

Sir—I have read with interest the editorial on this subject in your issue of January 29. While the conclusion reached is eminently proper, you seem to have reached it in spite of the arguments you yourself advanced. While the patent on its face grants to the inventor the exclusive right, for a limited period, to make, use, and sell the invention, such a statement must be qualified by the clause "when the manufacture, use, or sale of said invention does not infringe any prior unexpired patent." The patent does not give a patentee any more right to make, use, or sell than he had before, because before the patent was obtained he had the same right to make, use, and sell. What the patent really grants is the right for 17 years to prevent anyone else from making, using, or selling the invention patented.

A patent is not a true monopoly, because it does not restrict the exercise of a right that was open to the public before the patent was issued. A true monopoly contemplates a restriction that operates to prevent the exercise of a right which was open to the public before the monopoly was secured. This distinction between a monopoly and a patent, being not usually recognized, has led to confusion and, as in your article, to the questioning of the value of the whole patent system. It must be recognized that a patent covers something new, not theretofore known or used, and the public is not constrained to use the new device or process, being at perfect liberty to continue to use the device or process which it had theretofore been using. If the invention is broadly new and meritorious and effects a considerable saving over the methods of the prior art, it is in demand; and in return for permitting the use of the invention, the inventor is clearly entitled to receive a consideration. The fact that in certain isolated cases onerous conditions are imposed, should not lead to the conclusion that the whole patent system is at fault. A man owning a piece of desirable property is at liberty to ask whatever price he desires, and if his price is exorbitant, the property will remain in his possession, regardless of its desirability. The same condition is true with regard to patents and, in fact, everything else; that is, the price is regulated by the supply and the demand.

Your editorial states, further, that the granting of patents has not done away with trade secrets and it is often questionable whether an inventor should patent his process, disclosing his method, or keep the process secret. This relates entirely to processes and the condition is brought about, not by the reasons advanced, but on account of the fact that it is often difficult to obtain evidence that a manufacturer is infringing the process. A process patent covers a certain sequence of steps, not the product of these steps, and from the product it is impossible to determine its process of manufacture. If the process is carried on in the factory behind closed doors, the inventor may not be able to obtain the necessary evidence to prove infringement and for this reason some processes are kept secret and not patented.

Your remarks concerning the Victor phonograph are perhaps true, but it must be remembered that the patent gave them a virtual monopoly of the use of disc records for 17 years, during which time, by the expenditure of millions of dollars in advertising, they have made their trade-mark of great value. The patent, however, has now expired, and we find a dozen competitors in the field with machines using disc records. It cannot be successfully contended that a condition which granted them a monopoly of disc records over such a period of years and permitted them to build up their business without competition, was of no value.

The editorial further states that the language of a patent description is often cryptic intentionally. While this may be so in a few isolated cases, it is by no means common and is not considered good practice. A description is often necessarily somewhat indefinite due to its very nature. When an invention is conceived in the mind, it is conceived in its generic form, but when the idea is presented in a drawing or description, it must necessarily be embodied in a specific form. As soon as an idea is expressed in concrete form, it immediately becomes specific. The specific structure, however, is not the invention, but only one embodiment of it; in the description and claims, the inventor desires to express his generic invention; and since language is such a clumsy tool with which to express our thoughts, the description and claims are often obscure.

Exception must also be taken to the inference that the patent system is to be blamed because the inventor is often unable to exploit his invention commercially, due to lack of finance, and must sell his patent. This condition is in no manner chargeable against the patent system, but to our economic system in general and to the natural laws of the world. I have seen several instances of late, where inventors have sold their patents to corporations who were qualified to exploit them commercially and in every instance, the inventor was greatly pleased with his trade. The fact that the corporation takes the risk, expends money in exploiting and manufacturing, and makes a profit, is not reprehensible and should not be so considered by right-minded persons.

I am of the opinion that the patent system in this country has done more to advance this country to its present high state of civilization than any other influence of which we are aware. The desire to gain has been the incentive not only to thousands of independent inventors who have contributed greatly to our advance, but has caused corporations to install research labora-

tories, and operate them at large expense, in an endeavor to bring forth the secrets of the unknown.

I fully agree with you that the man who would abolish the Patent Office should pack his few ancient devices and take to the tall timber.

H. G. Prost.

[This subject is one of particular interest at this time. Other letters will appear shortly.—Editor.]

The Mechanical Efficiency of Crushing

The Editor:

Sir—None of the arguments of my criticism of an article by Mr. Algernon Del Mar on the above subject, has in his recent reply of November 27, 1915, been opposed or contradicted, but, pluckily on his feet again, he challenges me upon new issues.

In fairness to Mr. Del Mar, I willingly admit that by devoting his full energy to his own business, some of my writings may have escaped his notice, but I am entitled to expect him to look them up if he goes out to kick at "Stadler's theory," and more so, if he accuses me of indulging in personal reflections, instead of giving facts and proofs in support of my contentions.

Not long ago I wound up the controversy on the laws of crushing, in a lengthy and comprehensive article,* in which I also tried, at first in a friendly spirit and in decent form, to convince Mr. Del Mar and Mr. Gates of the incorrectness of the views expressed by them in earlier articles in the same journal. Ignoring my criticism, they both reiterated their ill-considered arguments and statements in another periodical, quoting each other as authorities. Poor Lord Kelvin! His theoretical proof of the law of work based on the property of matter,† has broken down in the light of the results of Mr. Gates' experiments. The maxim of Mr. Del Mar, that such problems "are being unsettled every day," did not however guide the French astronomers, for whom the apparent irregularities of the orbit of Uranus had been the cause of great perplexity for many years, until they discovered Neptune.

Returning to our own petty troubles, I proceed to answer Mr. Del Mar's question: "Will Mr. Stadler procure and give to the public the results of these (referring to the experimental work of the Mines Trials Committee in Johannesburg) investigations?" In anticipation of such reasonable demands, I approached the Committee, while in their employ, twice on this matter, the first time suggesting to them the advisability of being instructed to sum up the intermediate reports on the progress of the work in a final comprehensive one, and the second time, when the Committee was already in a moribund state, asking for permission to make use of the data in my possession for the purpose of publication. Although both applications have been rejected, I am on my side quite prepared to overcome my moral scruples of committing a breach of confidence, if I am backed up a little in my taking the view that now, after the collapse of the organization, the information and experience gained can no longer be withheld from the investors of the participating companies by self-constituted trustees.

Quoting from memory, Mr. Del Mar believes that I had stated, "that the comparative efficiency of stamps and tube-mills on the Rand varied [he means compared] as 70:17, or 4:1. Any practical operator knows that this is not so with respect to tube-mills in other localities." By omitting the fact that these figures referred, as explicitly stated, to the conditions of a specific test given as an example, the quotation is not a correct expression of my views. In the reply to the discussion of the paper from which the quotation is taken, further examples were published, and in commenting upon the results, due attention was drawn to the rapid decrease in the efficiency of stamps with the increase of the fineness of the battery-screens. From the results of the investigation by the M. T. C. it appears that the merits of the three methods of crushing: single stamp, stamps and tube-mills combined, and single tube-mill grinding (Giesecke mill) are so close, as regards the mechanical reduction efficiency, that the final decision in each case depends upon other considerations, such as metallurgical requirements, nature of the ore, local conditions, etc. In any case, the investigation clearly proved that nothing would be gained by the promotion of the tube-mills from auxiliary to primary grinders.

These results were subsequently confirmed by a gigantic trial-run carried out on a practical working scale by several of the biggest mines on the Rand. Based on an imaginary crushing law, Dr. Caldecott and his friends evolved and inaugurated in 1909-1910 a 'new metallurgy' through which Rand practice was to be revolutionized by shifting the greater portion of the crushing work from the stamps to tube-mills. At the time when enthusiasm as to the marvels to be achieved by this innovation reached its height, we were led to believe that by simply hanging up a portion of the stamps and buying so many tube-mills at so much per dozen, millions of tons of low-grade ore would be brought within the economic limit. The metallurgical advisers of the East Rand Proprietary Mines made Sir George Farrar say at the March meeting in 1910 that they intend "to crush with 440 stamps more than we do now with the whole of our 820 stamps, with consequently much decreased costs." The 'new metallurgy,' based on Rittinger's law, has had its trial! The non-fulfillment of the unwarranted promises was the intrinsic cause of the debâcle of the E. R. P. and of the simultaneous depreciation of the share-market valuation of Rand scrip by about one-third. Yet such trifles are so easily forgotten, and Rittinger's theory is still alive.

H. Stadler.

†Sir William Thomson and Peter Gutherie Tait: 'Treatise of Natural Philosophy,' Vol. II.

Account Systems for Small Mines

*Elaborate book-keeping is the general custom with large mining companies, requiring a numerous staff. While this is not necessary at small mines, yet a simple and reliable method is desirable. This should be in sufficient detail to be able to tell quickly the grade of ore, prices received for metals, costs per ton for mining and milling, costs per foot for development, upward or downward tendencies in costs, ore settled or in transit, cash on hand, stocks of supplies on hand, efficiency of labor, etc.

As in all accounting, there are two main divisions; that of revenue received for what is sold, and that of disbursements made for what is bought, so in mine accounting there is to be considered chiefly the income derived from sales of ore or concentrate, and the expenses incurred in producing these in a marketable condition. The cash and voucher-record, as a single book, preferably loose-leaf, has met with general approval in recent years as a combination of cash-book, journal, and voucher-register, and is the only record at the book-keeper's desk from which posting is done to the ledger. It is compact, convenient, and desirable, serving the purpose of gathering numerous items into their proper sections at original entry, and requiring that they balance before they are used in further calculations. This book may have columns for cash, bank-accounts, operating accounts, and various non-operating ledger-accounts. It seems scarcely necessary to do more than sketch the use of this record, since its cash columns correspond exactly to those of a cash-book, and journal entries are made in it double, as in a journal, the only difference being that the amounts are listed in columns so that they are easier to refer to and to total. Totals only are posted to the ledger, so that posting is a short and simple matter. This is done but once a month, after closing the month's operating accounts.

In expenditure a distinction is drawn between direct and indirect operating costs, the former being, as the term indicates, those incurred for actual handling of ore, and the latter those necessitated by the operation of mining in general. A large operating company has the following accounts for its smaller properties: 1. Direct.—(a) development; (b) ore-breaking and stoping; (c) timbering; (d) tramming; (e) hoisting; (f) sorting, weighing and loading; (g) draining. 2. Indirect.—(h) branch-office; (i) salaries; (j) general and New York expense; (k) insurance; (l) taxes; (m) laboratory; (n) marketing; (o) transportation. For a concern operating a mill, the number of accounts is increased by the addition of sampling, mill-experimental work, and milling. Only the last-named requires a further sub-division in order to give more definite information as to the work and the efficiency of the various departments and machines. General expense, if care is not exerted, may become a dumping-place for items which ought properly to be distributed to accounts to which they pertain. The heading 'miscellaneous' is practically taboo, except as the designation of a department in which details are shown.

The actual procedure in accounting for expense items comprises the following steps: (1) making the voucher; (2) entry in cash-voucher record; (3) entry in distribution book; and (4) summary on cost sheet or monthly report. A comprehensive survey of operations is completed by making up a financial statement, by adding the totals of income (separating the amounts according to the classes of ore sold, if desired) and deducting the operating expenses therefrom. This is made up and entered as a voucher also, the balance being charged into profit and loss account.

All charges to the power, mechanical or electrical and supply departments are divided at the end of the month according to the purpose for which the electric current or supplies were used, or the work done. For example, charges for current are pro-rated, according to kilowatt-hours or horse-power, to mine-compressors, pumps, locomotives, hoist-motors, framing-shed motors, sorting-plant motors, mill-motors for driving various machines, etc. In a similar way, mechanics' and electricians' time may be re-distributed by the use of cards specifying hours worked on this or that job, and repair parts used on the same. Thus proper charges may be made against the various motors, engines, and machines, cars, track, trolleys, lights—against any part of the plant, in fact, for the benefit of which this diverse work may be done. No hair-splitting is necessary or at all desirable.

Two other matters, which are closely related, naturally come under the control of the mine accountant, namely, the ordering of supplies, and the keeping of stock, and taking of inventories.

In adopting a system of accounting, a thorough study should be made of the conditions at the mine where it is to be installed, bearing in mind also the needs and desires of the management and the stockholders in the matter of reports. Once a system has been adopted, it should be adhered to religiously, and the seeming advantages of some different system should be well considered and tried out before any change is made.

*Abstract from paper by James E. Chapman prepared for the Arizona (September 1916) meeting of the American Institute of Mining Engineers.

Shoveling is at its best in the lead and zinc mines of Missouri. A. G. Barton, superintendent of the Galena Booster mine at Neck City reports that a man named Tom Woodmancy shoveled 104 cans (52 tons) in an 8-hr. shift, went home, got married, and the next day shoveled 108 cans, or 54 tons.

Washington has an area of 69,180 square miles which is about the same as Missouri but less than half the area of California. Washington's population is 1,500,000, having trebled since 1900. Spokane, Washington, population 140,000, is a convenient centre for Coeur d'Alene mining.

Electrolytic Zinc

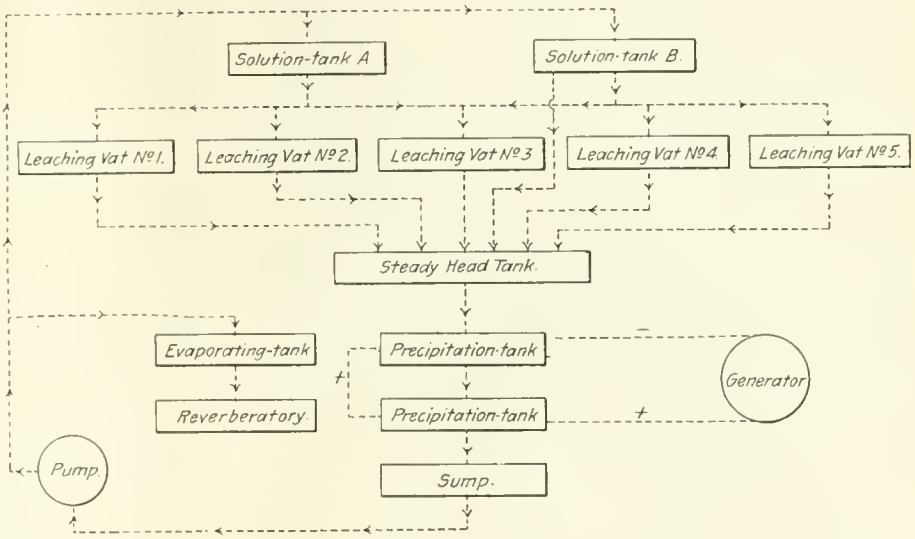
By Harry A. B. Motherwell

AT the present time when electrolytic zinc is occupying so prominent a place, the following notes on the Bradley-Williams process of zinc production as used in a demonstration run in 1910 may be of interest. The Bradley-Williams process was originally worked out on the ore of the Rhodesia Broken Hill mine, this being essentially a lead carbonate with zinc silicate and some carbonate. The lead content runs about 33% and the zinc about 15%, of which about one-fourth is present as carbonate. Very little lime or magnesia is present in the ore, but traces of copper, arsenic, and vanadium are found.

The process consists of leaching with an acidified solution of zinc sulphate, passing the solution through electrolytic precipitating-tanks fitted with lead anodes to deposit the zinc at the cathode, and returning the solution to the leaching-vats. A claim was made that "the leaching takes place, not only by virtue of the solvent action of the sulphuric acid, but by an electrified solution of zinc sulphate carrying powerful oxidizers."

This process is continuous and practically regenerative, requiring but a small amount of sulphuric acid to be added daily to account for that consumed by the carbonate of lime and sulphatization of some lead. The intention was to grow cathode zinc for as long a period as practicable, then to remove the cathodes, and by dipping into a bath of molten zinc melt off the surplus deposit of metal, and withdraw the cathodes ready to be put back in the deposition tank. A cast-iron bath, 6 ft. by 2 ft. 6 in. by 1 ft., was filled with pure zinc and kept at a proper temperature with its surface protected from undue oxidation. At intervals, zinc would be ladled from this bath and cast into ingots. An account of the difficulties encountered may be of interest.

The accompanying flow-sheet of the experimental plant shows five leaching-vats, one of which was filled each day, giving fully four days treatment, which time was sufficient to reduce to under 1% the zinc content of the tailing. The leaching-vats were fitted with a false bottom like cyanide-vats and need no description. The steady-head tank was to regulate the rate of flow and acidity of the solution of the precipitation-boxes. The anodes were of hard lead (6% antimony), the plates were 66 by 20 inches and $\frac{3}{4}$-in. thick and the cathodes were of similar area, but of $\frac{1}{4}$-in. rolled steel galvanized. The electrodes were spaced $\frac{3}{4}$ in. apart.



It was soon found that the surface line of liquid on the cathode became eaten down to the bare iron, and on dipping in the zinc bath, this line would not take on zinc without being first cleaned and pickled. It was impossible to pickle before dipping, as the rough zinc alongside the line destroyed the hydrochloric acid used, before the iron surface was clean. The water-line was then protected by a coating of varnish or paraffin wax, but it was found that if this protecting and insulating material extended $\frac{1}{2}$ inch below the surface of the liquid, the increased C. D. along the junction of the zinc and paraffin quickly caused 'trees' to short across to the anode. This difficulty was overcome by raising the level of the surface of the liquid in the tanks by $\frac{1}{2}$ inch during the first 12 hours the plates were in use, thereafter lowering, by 12-hour stages, $\frac{1}{8}$ of an inch at a time, so that after the first 12 hours there was an increased thickness to be corroded. A considerable improvement, however, was made by changing the shape of the cathodes. These were cut-down so that they were completely submerged in the electrolyte, except for a piece at each end to make the connections (see Fig. 3). A very much better deposit was obtained on these.

The first plate was able to be kept in for over 50 hours, which was improved upon later. The gas seemed to escape from the top of the plate much better, and there was no 'treeing' along the top. At first some trouble was caused by 'treeing' along the bottom edge of the plate, this causing short circuits and consequent loss of power. This sprouting was also harmful in so far that all flakes of PbO_2 from the anodes were caught, and made short connections across, starting local action on the cathode; also those small pieces of PbO_2 would stick on the rough surface and contaminate the zinc

when melted. Eventually the anodes were cut ½ inch less in depth than the cathodes. This remedied matters much by decreasing the C. D. along the bottom line of the cathode.

Another trouble arose with the feed of solution to the boxes. This incoming liquid, being heavier, went to the bottom of the box. The flow of solution, coupled with the arrangement of the electrodes parallel to it, caused bare patches of iron where the liquid first touched the cathode. This was righted by a baffle-board, causing the incoming liquor to first descend and then rise to the surface mixed with the liquor of the vat before it entered the compartment in which were the electrodes.

The next trouble arose with the anodes. After the plant had been about three weeks in operation, it was found that the anode plates were peeling badly; quite large flakes of PbO_2, falling between the electrodes, were held resting against both anode and cathode. Whenever this happened the zinc on the cathode was dissolved quickly and a spot of bare iron appeared. Even if the flakes were removed, the damage was done, as the iron and zinc couple set up a local action, and the zinc on the cathode was rapidly eaten away, with large evolution of hydrogen gas. Once started, the patch of bare iron increased in area so rapidly that a few hours sufficed to dissolve all the zinc from one side of a cathode even with 40 hours growth on it. Careful watching of the boxes enabled many a cathode to be caught when the destructive work had just begun, but unfortunately there was trouble ahead still, for those injured cathodes when dipped would not take any zinc on the bare patches.

The shape of the cathode also led to considerable trouble.

The work was done in mid-winter in England. The zinc bath was at one side of a room and close against an interior brick wall. That wall retained some heat. When a sheet of steel ⅛ inch thick and 5½ ft. long was heated to the temperature of molten zinc, then hoisted above the bath and suspended there to drain and cool, it very naturally took a slight curve, as one side was exposed to the cold air and the other to the radiated heat from the wall. The cost of stripping, pickling, straightening, and re-galvanizing practically killed the method of collecting the deposited zinc, and the old practice of making starting sheets was adopted, that is, dipping in molten paraffin wax and then coating with graphite rubbed on with a brush, and stripping the deposited metal whenever it became necessary. The cathode sheet then required only re-graphiting before being put back. Much time and trouble were saved and the plates were not buckled. With the spaces between electrodes so very small it is essential that the plates be quite straight. To overcome the trouble of short circuits due to flakes of PbO_2, an experiment was tried by putting on each side of the anode a sheet of corrugated and perforated celluloid, such as is used in some batteries. This seemed quite satisfactory, but it is well worth noting that celluloid is highly inflammable and a spark across might set it alight; therefore it should be totally submerged. Workmen about the lead anode tanks in a copper refinery occasionally have a firework display that teaches caution.

Why there occurred such heavy disintegration of the anodes was never quite decided. Probably many factors could be counted. Lead anodes after many years in use in a copper plant at a voltage of 2 showed little wear. At a voltage of under 2, however, only lead sulphate is formed; but bring the voltage up to 4 and peroxide is formed. Part of the rapid destruction may have been due to the presence in the ore of vanadium, which is a powerful oxidizer and accumulates in the solutions. The sump-solution gradually assumed a blue tint, which at first was supposed to be copper accumulating in the liquor. After a few days the characteristic changes from green to pale lavender were noticed, thus indicating the presence of vanadium. I held the opinion that much of the destruction of the anode was due to frequent stoppages of the current. The dynamo supplying current was driven by a motor that in turn derived its supply from the public mains. For some cause unknown, almost every other night the supply was either ceased for a few minutes or a fuse was blown, stopping the motor. With the tanks acting as accumulators or storage-batteries, or rather more correctly, acting as primary batteries, the current was reversed when the dynamo stopped. Each time this happened the loose peroxide would be thrown off on re-starting the dynamo. A somewhat parallel instance will be found in gold-refining by the Wohlwill process, where an improvement is made by sending simultaneously with the direct current an alternating one, which by its vibrations dislodges all the silver chloride from the anode as soon as formed. Copper had not accumulated in the solution to the extent of necessitating its removal before precipitating the zinc. In an account of Nordhausen's process of electrolytically refining zinc the following is stated: "The product handled is spelter ladled from the ordinary refining-furnaces nearest to the underlying lead. * * * Impurities taken into the electrolyte from anodes being precipitated by zinc-dust. If the spelter carries 1% copper, then 1.1% zinc is required on the weight of spelter used. The E. M. F. is 0.5 to 1.0 volt, and C. D. is 10.1 amp. per sq. ft." With soluble anodes, of course, a much lower voltage is required than with insoluble, as when depositing from a solution obtained by leaching ore. The voltage used was 4 and C. D. 9.5 amp. per sq. ft. of cathode area. Undoubtedly the efficiency was low, but many conditions had to be accepted as they were found. The main leads were copper rods 1.75 in. diam. (a sectional area of 2.4048 sq. in.), which with 1630 amp. = 677 amp. per sq. in. Taking 0.00266 lb. as theoretical zinc per ampere-hour, total amp., 1630; 11 cathodes; time, 92.33 hr.; zinc obtained, 19 lb., we get 35.24 lb. theoretical deposit and 53.9% efficiency. If we take it that usually the practical deposition is round about 80% of the calculated theoretical, then the 53.9 is raised to close on 70%

of the general work done. At the time of this efficiency test the electrolyte carried only 8% $ZnSO_4 7H_2O$ in place of the usual 13%. The cathode was rolled steel $\frac{1}{8}$ inch thick, galvanized, waxed, and graphited. Eleven cathodes and 12 anodes were in each tank; electrodes were spaced $\frac{7}{8}$ inch apart; free acid was 0.25% H_2SO_4.

All these troubles in connection with the precipitation were finally overcome. The margin allowed in the matter of free acid-content is small. If allowed to fall below 0.1% free H_2SO_4 the deposit is of a dark color and

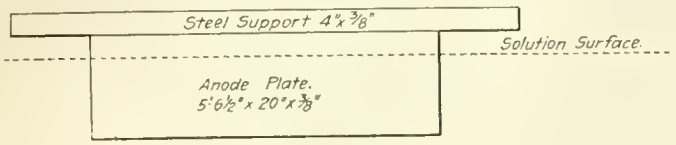


Fig. 1

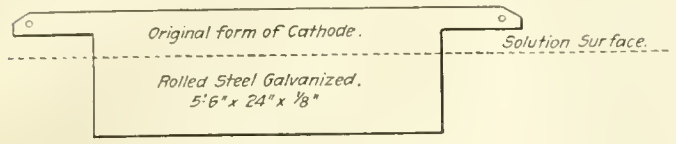

Fig. 2

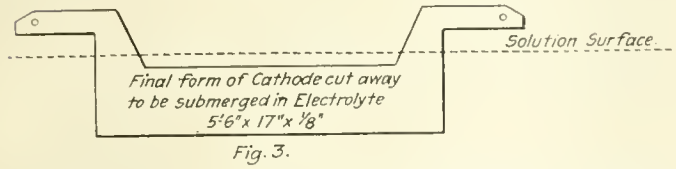

Fig. 3.

a spongy nature and carries considerable impurity. There is much loss by oxidation and formation of dross in melting a deposit of this nature.

With the quantity of solution on hand it was found that the electrolyte required to be fed to every second or third tank, as more than that in series (as to flow of solution) rendered it too acid for the later boxes. There is some doubt if it would be possible on this ore to produce a zinc of quality sufficiently pure to compete with the Brunner-Mond electrolytic zinc, but a high-grade spelter can be made. If the situation of the mine from which the supply of ore was obtained be considered, one would say that impure spelter was all that was desired, the obvious market being the Rand goldfield, where pure zinc is not wanted. The ore with 32% lead and 15% zinc, all as carbonate and silicate, is not wanted by any metallurgical plant, but tailing with the following approximate content seems quite desirable as a source of lead:

	%		%
SiO_2	16	Zn	0.8
Fe	11	S	1.2
Al_2O_3	5.5	Pb	48.5
CaO	0.25		

The most serious difficulty encountered in the treatment of this ore lay in finding a method by which the electrolyte could be freed from accumulating silica. Much silica naturally passed into solution, and in time would present a serious problem on a large plant. This difficulty did not appear till after some months running, and, on the small-scale operation was met by withdrawing from circulation daily some of the sump-solution, evaporating to a pasty condition, and baking hard in a reverberatory to dehydrate the silica. The product of the furnace was spread on top of the next vat undergoing treatment, and gave no trouble in leaching. It contained 34% silica.

Wolframite Mining in South Dakota

By Edward Manion*

†For years the Wasp No. 2 mine has been known for the low grade of gold ore extracted. It has also been known for some years that wolframite occurs in the mine, and in May 1915, it was found in commercial quantities. Since that time the company has mined 184 tons, averaging 45% tungstic acid. The wolframite occurs along fissures in the flat Cambrian quartzite.

The ore is taken to the ore-house, sorted, cobbed, crushed to about ½ in., sampled, and sold to the highest bidder. For the first shipment, which was made in July, $8 per unit was obtained for material carrying 48% tungstic acid; for the last shipment, in December, $51 per unit for 47% product.

A concentrating plant was recently constructed to treat the low-grade ore. This ore is crushed to ½-in. mesh by rolls, and from there it passes through a trommel of 16-mesh. The oversize goes to a jig, then to a small set of rolls, returning to the trommel. The undersize from the screen goes to a cone-classifier, from which the agitated slime flows to canvas tables, and the sand to Wilfley tables. The sand from the latter goes to a 4 by 5-ft. ball-mill, discharging into an 8-in. elevator, which raises and returns the re-ground sand to the classifier. Slime goes from the classifier to nine 4 by 60-ft. canvas tables, which catch the concentrate, the slime passing to a launder at the end of the tables, and from there to an 8-in. elevator, which deposits the treated slime into a 420-ton tank as tailing. The tailing that is high in gold is treated by cyanide.

Three grades of concentrate are produced, namely, 65%, 45%, and 35% tungstic acid, the last being slime from the canvas tables.

CHUTES for loading ore from the stopes into mine-cars have been lined with concrete in heavy ground in the Copper Queen mine. These are long chutes that concentrate the ore from two levels to a haulage-level. One concrete-lined chute used for 20 months required relining due to wear by sharp ore. For most of their height these chutes are 3 by 3½ ft. but are enlarged, for 30 ft. at the bottom, to 8 ft. by a maximum of 30 ft., in order to hold 90 tons of ore, there being an offset of several feet at the enlargement to make a baffle for the ore to fall upon, checking its downward velocity. The pile of ore is not allowed to extend up into the raise, which serves only as a passageway.

*Superintendent, Wasp No. 2 mine, Flatiron, South Dakota.

†Abstract from *The Pahasapa Quarterly*, South Dakota School of Mines, Rapid City.

Saving Fine Gold

Some gravels contain gold so fine that only a small amount is saved. The gold from the Snake River alluvial flats in Idaho is 945 parts fine, and the particles are so small that it takes from 1000 to 2000 colors to equal one cent, according to J. M. Hill in Bulletin 620-L of the U. S. Geological Survey. The largest pieces of gold are scarcely 0.01 in. diameter, while many can only be distinguished by a high-power microscope. The larger flakes are cupped. Most of the gold is bright-yellow, but some is red-brown, due probably to a coating of iron hydroxide.

Along the course of Snake river can be seen the wrecks of numerous attempts to extract the fine gold from the gravels. The remains of dredges are seen here and there, and many more have been removed. Countless process machines have been tried there, but so far as known without success. Most of these machines have depended on amalgamation, but many different methods have been used to get the quicksilver and gold into contact.

The rocker and sluices are still used, and a sluice of special type, known as the burlap-table, used also on some of the dredges, has proved one of the best appliances for saving the fine gold. This is shown in the accompanying sketch. In working with burlap-tables the main sluice leading from the working A, is set at any convenient grade. Near the lower end is a section with a perforated-steel bottom B, which allows the fine heavy sand and gold to drop through to sluices set at right angles to the line of the main sluice. The transverse sluices C, are in reality launders which deliver the sands to a series of burlap-tables E. Each burlap-table is from 16 to 30 ft. long and 3 or 4 ft. wide. It is usually set at a grade of 1 to 12 in., but the grade needs to be adjusted to meet different conditions. Most tables are built with two drops at least. The pulp from the launder-sluices is fed to the burlap-tables through adjustable openings D, so that it flows over the table in a thin, even sheet. The heavy sand and gold are caught by the rough surface of the burlap, and the light sands run to waste. In some places the tailing is re-run. In operation, the tables are cleaned as often as necessary, by taking up the burlaps and washing them in tubs of clear water. The concentrate, together with that washed from the bottom of the tables, is either placed in a grinding-pan or revolving barrel, for treatment with quicksilver and weak cyanide solution, or cleaned with a rocker. The latter method, while attaining somewhat better results than the simple rocking of the gravels, is not efficient. In some of the burlap-tables the first section of the table—that nearest the launder-sluice—has a silver-plated copper-bottom coated with quicksilver, for amalgamating the gold. In the sketch six tables are shown on each side of the main sluice. The number of tables varies with different conditions. In some places all the tables are on one side of the main sluice. In fact, each operator has his particular design of table and method of handling the gravel.

Both suction-pump and bucket-dredges have been used for lifting the gravels. Probably the most successful dredging operation on the river was the Sweetzer-Burroughs dredge, which was operated 30 miles west of Minidoka. The first boat built by this company, in 1894, was of the suction type, but the company later constructed a bucket-dredge having a capacity of 2000 cu. yd. a day. Concentrate from burlap-tables was amalgamated in barrels. It is estimated that the cost of handling the gravel was from 4.5 to 5.5c. per cubic yard.

Within the last few years experiments in cyaniding the gravels of the Snake river, while not a financial

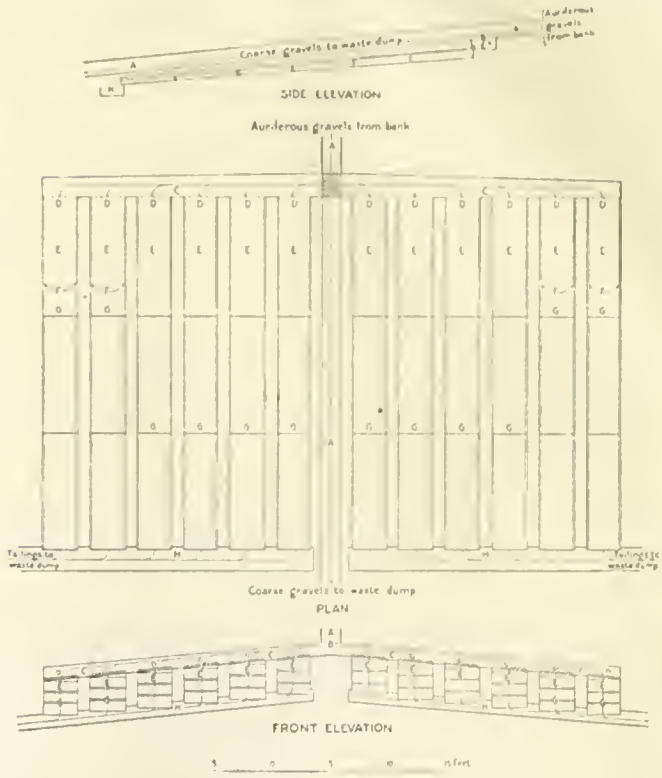

DIAGRAM OF BURLAP-TABLE FOR SAVING FINE GOLD.

success, have at least shown that the method has merit. At a plant 16 miles south-west of Blackfoot, the gravel was screened through a $\frac{3}{16}$-in. mesh trommel. All the undersize was leached: no difficulties were met with in the leaching-vats.

ELECTRIC PLUNGER-PUMPS were discussed by Chas. Legrand of Douglas, Arizona, at the San Francisco meeting of the A. I. M. E. in September. He stated: "I prefer the vertical type of electric plunger-pumps as giving more even wear on packing and plungers and taking less floor space, although requiring more head room."

VANADIUM ORE is being mined at Vanadium, San Miguel county, Colorado, by the Primos Chemical Co. This, it is said, is the only active vanadium mine in the United States, although, of course, the carnotite mines produce vanadium as a by-product with radium.

BUOY. To keep from sinking, to keep afloat in a liquid.

Geology of Tungsten Deposits

By J. J. Runner*

†ALTHOUGH relatively a rare metal, tungsten is, contrary to popular opinion, widely distributed in nature. It is known to occur, although not in commercially important quantities in 19 of our States and in Alaska.

Tungsten occurs chiefly as the tungstates of iron and manganese, or of calcium, in the minerals, ferberite, wolframite, hübnerite, and scheelite. The difference between the first three of these minerals is of scientific rather than technical value; hence they will be discussed together.

Ferberite, wolframite, and hübnerite form an isomorphous series from $FeWO_4$ to $MnWO_4$. When the mineral is pure $FeWO_4$, or contains only a small percentage of manganese, it is called ferberite. Hübnerite is pure $MnWO_4$ or may contain a small percentage of iron. Wolframite is $(FeMn)WO_4$, in which the ratio of iron to manganese is more nearly 1 : 1 than in either of the other two. The following analyses will serve to illustrate:

	Tungstic oxide.	Ferrous oxide.	Manganous oxide.
Ferberite	75.68	24.47	0.12
Wolframite	76.00	16.00	7.70
Hübnerite	75.58	0.25	23.40

It will be noted that in all of these the percentage of tungstic oxide is nearly 76.

The minerals of this series vary from dark-brown in the varieties high in manganese to nearly black in the ones rich in iron. The streaks are dark-reddish brown to brownish-black. The common forms are tabular masses, disseminated grains, and in columnar crystals. Cleavage is perfect in one direction at right angles to the direction of elongation in the tabular forms. The hardness is about that of ordinary glass, the hardest being those rich in manganese. Specific gravity ranges from 7.2 to 7.5, the varieties high in iron being the heaviest. Lustres are sub-metallic. Among minerals frequently mistaken for the minerals of the wolframite series are hematite, magnetite, graphite, columbite, and cassiterite. The first three may be readily distinguished by their inferior weight and the last two by their inferior cleavage.

Scheelite, the tungstate of lime, $CaWO_4$, occurs in double-ended square pyramids and in massive forms. In color it is white, pale yellow, pale brown, greenish, or reddish. Its lustre is vitreous; the cleavage fairly good in four directions; the hardness is about 5 or less than that of ordinary glass; specific gravity about 6. Most specimens are translucent or transparent. It may be distinguished from the other minerals resembling it in color by its superior weight.

Other minerals of tungsten are:

Cupro-tungstite, $CuWO_4$, tungstate of copper.

Cupro-scheelite, $CuCaWO_4$, tungstate of copper and calcium.

Stolzite, $PbWO_4$, tungstate of lead.

Powellite, $Ca(MoW)O_4$, tungstate and molybdate of calcium.

Tungstite, WO_3, oxide of tungsten.

Meymacite, hydrous-oxide of tungsten.

The world's commercially important deposits of tungsten are almost wholly confined to the following five modes of occurrence: (1) quartz veins; (2) pegmatite dikes and tin-stone veins; (3) placers; (4) contact zones on the borders of intrusive igneous rocks; and (5) replacement deposits. Of these the first three are far the most important.

Among rocks, granite, granitic gneiss, and their fine-grained equivalents, are by far the most common associates of tungsten deposits. In some cases the orebodies lie wholly within these rocks, in other cases they extend into slate, quartzite or other rocks at the side, but in a majority of cases igneous rocks of the acidic type are to be found near-by. This applies with equal truth to each of the five types of occurrence. Tungsten deposits are usually in or in close proximity to metamorphic rocks also, such as slate, schist, quartzite, or crystalline limestone, for the very intrusion of the granite itself has in many cases brought about the metamorphism.

The mineral associates of tungsten also are well defined and characteristic. It is commonly accompanied by one or more of the following: quartz, muscovite, cassiterite, topaz, tourmaline, fluorite, beryl, biotite, bismuth, molybdenite, pyrite, arseno-pyrite, chalcopyrite, galena, sphalerite, gold, silver, and graphite. In the orebodies the tungsten minerals may occur finely disseminated and scattered through the gangue; they may occur in masses of various sizes up to a weight of many pounds, irregularly distributed throughout the orebody, or they may appear as crystals lining cavities. Many veins exhibit a banded structure with the tungsten minerals concentrated in definite layers, especially along the vein-walls.

Some interesting characteristics of a few of the commercially important deposits are as follows:

Those of Boulder county, Colorado, the principal source of tungsten in the United States, lie on the eastern slope of the Front range of the Rocky Mountains, about 30 miles north-west of Denver. The veins are

*Professor of Mineralogy, South Dakota School of Mines, Rapid City.

†Abstract from *The Pahasapa Quarterly.*

narrow fissures in granite and in porphyry dikes, accompanied in places by breccia. The ore-mineral is ferberite, finely disseminated through quartz or lining cavities. The deposits have been opened to a depth of 600 ft. and are said to show no signs of impoverishment.

Second in importance among American occurrences are the deposits of Atolia, in San Bernardino county, California. Here the ore-mineral is scheelite, in seams and veins varying from thin stringers to widths of four feet, in grano-diorite and schist. The gangue consists of quartz, calcite, and crushed country-rock. The ore is at present being mined down to 600 feet.

In the Dragoon mountains of Arizona hübnerite occurs in vertical quartz veins in granite, with a little muscovite and fluorite. The hübnerite occurs distributed through the quartz in tabular masses, some reported to weigh 500 lb., and in layers along the vein-walls. In the Arivaca district of the same State, hübnerite occurs in tabular masses and blade-like crystals in gold-bearing quartz veins.

In White Pine county, Nevada, hübnerite and scheelite occur in quartz veins occupying fault-fissures, associated with fluorite, pyrite, muscovite, and minerals of copper, lead, zinc, and silver. The veins range from thin stringers to thicknesses of 11 or 12 ft.; some are very rich.

In the northern Black Hills of South Dakota deposits of wolframite lie in the Cambrian dolomite, associated with the flat-lying masses of refractory silicious ores, north of Lead, and on the divide between Yellow and Whitewood creeks south-east of Lead. The wolframite appears in flat, horizontal, but irregular masses, and in many places seems to form a rim around the silicious ore-shoots, except on the under side. In other places it is found in thin stringers. Its mineral associates are pyrite, fluorite, barite, and occasionally gypsum.

Near the granitic area of Harney Peak in the southern Black Hills, wolframite exists in pegmatite. Similar occurrences have been found near Tinton in the Nigger Hill district. In the southern hills also, quartz veins bearing wolframite, tourmaline, muscovite, and graphite are being worked for their tungsten content. The veins dip steeply, cut across the bedding of the slate for the most part, in lenticular masses from a few inches to 2 or 3 ft. wide. The wolframite is inter-grown with quartz in tabular masses in places estimated to weigh 8 or 10 lb. Many of the veins show a banding parallel with the walls.

In Burma and the Shan States, which have become the world's greatest producers of tungsten, the ore is wolframite, found as nodules and granules in alluvial deposits. The parent lodes lie at the northward extension of the granitic backbone of the Malay Peninsula, which farther south has furnished the great tin deposits of the Malay States. In these lodes the wolframite is associated with quartz and tin-stone. At present mining is confined to the placers.

In Portugal, which ranks third as a producer, wolframite is accompanied by scheelite and tungstite, in veins and stockworks, with cassiterite, pyrite, chalcopyrite, arseno-pyrite, and often mica, tourmaline, and fluorite.

In Cornwall, greenstones and slates have been intruded by granite, and these in turn by dikes of quartz porphyry. The mineral-bearing lodes are for the most part parallel with the dikes, and in many places occupy fault-fissures. Impregnations of country rock along the lodes are common. Within the lodes the ore is irregularly distributed in bunches and pipe-like masses. The ore mineral is chiefly wolframite, with which is found cassiterite, pyrite, arseno-pyrite, chalcopyrite, quartz, feldspar, and tourmaline. Locally, ores of nickel, cobalt, lead, zinc, and uranium are found in the higher levels, while antimony, bismuth, and molybdenum have been produced in commercial quantities. The wolframite follows contacts between granite and slate.

In Spain deposits of wolframite are found in quartz veins with scheelite, cassiterite, mica, rutile, and feldspar cutting gneiss and gneissic granite, and in alluvial deposits derived therefrom.

In Bolivia wolframite is found in veins associated with cassiterite, bismuth, copper, and silver.

In Peru hübnerite occurs in veins following contacts of granite with slate and quartzite.

In Queensland and New South Wales wolframite occurs in quartz veins, in greisen, and in placers with chlorite, muscovite, biotite, topaz, fluorite, beryl, cassiterite, and bismuth and molybdenum minerals. The production of these two Australian States is of considerable importance.

The persistence of tungsten deposits in depth and the maintenance of metal-content are questions of vital importance. Unfortunately but few deposits have been developed sufficiently to determine their true nature, so that we have not enough data upon which to base definite conclusions.

Calumet & Hecla drilling practice, with the Carr bits on hollow inch steel used in mounted hammer-drills, employs a $\frac{1}{16}$-in. difference of gauge for each 22-in. change of steel, says the *Canadian Mining Journal*. On the Osceola lode, the difference in gauge for 7-in. steel is only $\frac{1}{16}$-in. for every second change or 44 in. For the tough, irregular conglomerate ore, as distinguished from drilling in amygdaloid and trap-rock, piston-drills are retained: the gauge is changed $\frac{1}{16}$-in. every foot, and a 'cross-Carr' bit has been devised for the conglomerate in which the single bit tends to fitcher. These improvements have increased the efficiency of the miners 40%, as the drilling speed varies inversely with the volume of rock cut or as the square of the diameter of the hole, and the reduced gauge has made it possible to start a hole with a much smaller diameter. Apart from this, the Carr bit drills but little faster than the ordinary cross-bit. No lugs are used on the steel for mounted hammer-drills but anvil-block chucks and plain shanks are employed. By drilling deeper holes for stoping (12, 14, and 16 ft. in amygdaloid and 10 ft. in conglomerate) a saving of 20% is made in dynamite.

The Flotation Process—II: Processes

By T. A. Rickard

*THE application of the physical principles outlined in the foregoing paragraphs has taken diverse forms, as expressed in scores of inventions, only a few of which have been developed into workable processes. The phenomenon of surface tension is used directly in the so-called skin-flotation methods of Hezekiah Bradford, Arthur P. S. Macquisten, and Henry E. Wood. In the first of these, invented in 1886, the pulp flows down an inclined plane onto the quiet surface of water in a vessel, so that the sulphide particles float forward under the impetus of their descent while the gangue particles sink. See Fig. 2. The explanation is that sulphides, by exposure to the atmosphere, attach films of air to themselves, so that they are not wetted and move over the so-called water-skin, while the gangue, which has remained wet throughout the operation, sinks through the surface to the bottom of the vessel.

Macquisten applied the same idea in a tube cast with a helical groove and revolved at a moderate speed. In 1906 this method was adopted in the Adelaide mill, at Golconda, Nevada. The ore contained 2.2% copper as chalcopyrite, with pyrrhotite and pyrite, as well as some blende and galena. The gangue was quartzose, containing spinel and garnet. The tubes were of cast-iron, 6 ft. long, 1 ft. inside diameter, and each weighed 450 lb. See Fig. 3. Externally these tubes were cast with two tires, which rested upon supporting rollers. The discharge-end was entirely open. The feed-end was closed except for a hole in the centre large enough to admit the pipe through which the pulp entered. Internally the tube was cast with a helical groove of ¾-inch pitch, which was changed subsequently to 1½-inch pitch. The discharge-end was connected with a separating-box, the joint between this and the tube being water-tight, while the tube was free to revolve. At the side of the separating-box, directly opposite the discharge from the tube, an opening or lip was cut for the overflow of the surface layer of water, carrying the floating mineral. This opening regulated the depth of water in the tube. The bottom of the opening was three inches above the inside bottom of the tube, so that there was three inches of water in the tube; the feed and the discharge were so regulated that the water passing over the lip was about $\frac{1}{32}$ inch deep. The tube was rotated at 30 r.p.m. in a direction corresponding with the helix of the interior. As Mr. Ingalls said:[1] "The pulp is thus screwed through the tube and in its advance is repeatedly given an opportunity to slide upon the surface of the water, where it may be retained by surface tension." The ore was crushed to pass 30 mesh. The capacity of each tube was 5 tons per 24 hours, and 25 tubes were in use. A concentration of 11:1 was effected on a 2.2% copper ore, the tailing assaying 0.2%; but this refers only to the deslimed ore, that is 70% of the supply, so that the actual extraction was only 63%. The inability to treat

METHOD OF SAVING FLOATING MATERIALS IN ORE SEPARATION.

No. 345,951. Patented July 20, 1886.

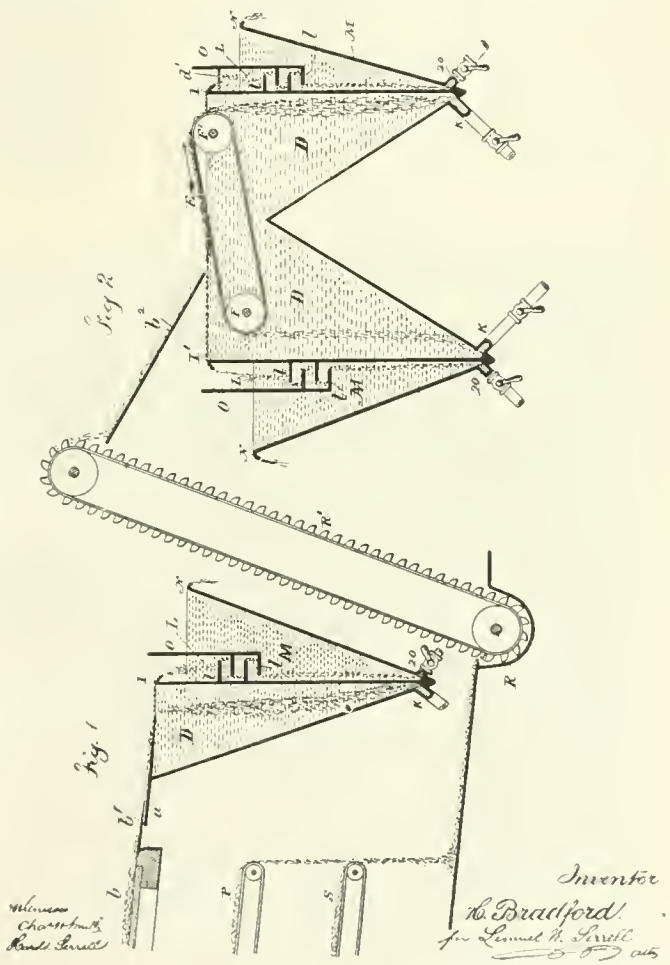

FIG. 2. REDUCED FACSIMILE OF BRADFORD PATENT.

slime is a notable defect of this ingenious method of flotation.

Wood's method is equally interesting. The ore is crushed dry to 30 or 40 mesh and is then fed in a thin stream from a vibrating plate onto the surface of water in a tank to the surface of which a forward movement is given by small jets, also of water. By a combination of the capillary attraction and the pressure of a con-

*Part of a paper under the same title read before the March 1916 meeting of the Canadian Mining Institute.

[1]The whole of the above description is taken from the admirable technical article by W. R. Ingalls in 'Concentration Upside Down.' *E. & M. J.*, Oct. 26, 1907.

stant feed, the sulphides are caused to move forward as a definite elastic film on top of the water. This film of mineral passes over an endless canvas belt, which emerges from the tank at a particular angle, varied according to the kind of mineral to be saved. The belt with its film of sulphides passes over three rollers so that its motion is reversed when it strikes the water-level of a second tank, where it releases its valuable burden.[2] Very little gangue in suspension comes over, as the water drains back into the main tank. Any submerged particles that have been accidentally wetted or are so heavy that they have penetrated the surface-film, pass to standard concentration-tables, on which they are separated by gravity in the ordinary way. In the case of molybdenite and graphite, the film concentrate is still further cleaned by being passed over a nearly vertical screen. Gangue in suspension passes through, while the flat crystals of the valuable minerals slide over the screen, which largely dewaters them. The flotation concentrate is collected and dried as usual. See Fig. 4.

Mr. Wood is using his own process to commercial advantage in the treatment of molybdenite ore, at Denver. The Macquisten tube is still in use at Mullan, Idaho; but the Bradford patent is only of academic interest. These methods have been confused with the more recent flotation processes; they ought to be differentiated. I suggest therefore that they be classed under 'film-suspension,' for it may be taken that in every case the sulphides are carried with air over the tensional film on the surface of the water.

Incidentally, it may be well to point out that although it is convenient to speak of the 'water-skin' and of 'skin-flotation,' the use of either 'skin' or 'film' is inaccurate. A skin is a thing of definite thickness, which therefore can be 'peeled' off, like the epidermis, for example. The phenomenon of surface tension involves nothing of the kind. It refers to a condition of molecular forces at the surface of a liquid, the effect of which can be only one molecule thick. Thus, 'water-skin' and 'skin-flotation' stand for water-surface and surface-suspension.

Neither Bradford nor Wood uses oil or acid, but in the later applications of the Macquisten tube both have been introduced. As the ore contains carbonates that would react with the sulphuric acid so as to liberate carbon-dioxide gas, it is obvious that another factor is introduced, namely, the bubble idea, which has proved so potent in the more recent phase of flotation. The further addition of oil marks a distinct departure from the first idea of the inventor, causing the process to resemble those of Potter, Delprat, and De Bavay.

The methods of these three Australians were alike designed to treat Broken Hill tailings, containing zinc-lead sulphides in a gangue composed partly of carbonates, notably calcite, siderite, and rhodochrosite. Charles V. Potter used water containing from 1 to 10% sulphuric acid, which was added to crushed ore placed in a vessel (see Fig. 5) provided with stirrers (*B'* the shaft and *B* the arms.) Heat was then applied by gas (31); whereupon the metallic particles rose to the surface of the liquid. It has been said that "it is clear that he (Potter) had in view a surface tension process."[3] If this is meant as a reference to the surface-suspension method, say, of Bradford, it is incorrect. Surely Potter used bubble-levitation as his principal effect. The gas generated by the action of the acidulated water on the carbonates joined with the air entrained by the ore is furnishing gas for making bubbles, this result being assisted further by the stirring of the pulp and the heating of it.

G. D. Delprat had an apparatus suggesting the employment of surface suspension, but he also used chemicals to induce flotation. See Fig. 6. By the addition (through the pipe 5) of a hot solution of acid salt-cake to the crushed ore as it was fed (from the chute 1) upon a pan having a sloping bottom (4) heated by a Bunsen burner (14), the sulphides were made to rise to the surface of the vessel (at 3, passing forward along 13), while the gangue collected in a sump (10). In this case also the flotation was the result of forming bubbles of carbon-dioxide gas and of air by chemical action and heat.

Auguste J. F. de Bavay described a process in which a thin stream of freely flowing pulp was delivered upon the surface of a vessel of water, after the style of Bradford. The description of the method as used subsequently on the North Broken Hill mine does not correspond with this, for in that plant the mill-tailing, relieved of slime, is said[4] to have been fed into a vessel provided with a mixing device, run at a high speed, so as to agitate the acidulated pulp. The sulphides rose to the surface, much in the same way as in the preceding methods of Potter and Delprat. That of Potter was used, in a modified form, at the Block 14 mine at Broken Hill in 1905 and 1906, while the Delprat process has been in use for several years successfully at the Broken Hill Proprietary mine. It is proper to add, however, that all of these acid-flotation methods are now only of academic interest. In the chief application of these processes it has not been customary to use oil, but as the material treated came from old dumps of tailing it may be assumed that there was some substance present capable of modifying the water sufficiently.[5]

The first application of any of the oil-flotation processes on a working scale in a mill was that made at the Glasdir mine, near Dolgelly, in Wales, by Francis E. Elmore in 1899. The mixture of crushed ore and water was fed[6] at the upper end of a slowly revolving drum,

[2]From particulars given to me by Mr. Wood himself. See also Trans. A. I. M. E., Vol. XLIV (1912), pp. 684-701.

[3]'Concentrating Ores by Flotation.' Page 9.

[4]*Ibid.* Page 115.

[5]This suggestion is made by Mr. Hoover in his book. On page 101 he says that "there may be organic substances in the ore which, upon the addition of acid, yield gummy compounds that selectively adhere to the ore." By 'ore' here he probably means 'sulphides,' that is, the blende and galena.

[6]Charles M. Rolker. 'Notes on the Elmore Concentration Process.' Trans. Inst. M. & M., Vol. VIII (1899-1900), pp. 379-384.

provided with annular helical ribs and transverse blades, so as to effect the mixing of the pulp and the oil without producing emulsification. See Fig. 7. The oil was introduced through a separate pipe. The mixture was discharged into a V-shaped vessel, where the water and sand subsided while the oil buoyed the sulphides to the top. An oil-residuum having a specific gravity of 0.89 was used in equal parts by weight with the ore, ton for ton. The oil was so viscous as to require the aid of small rotary pumps to propel it forward. The temperature of the oil and water was kept between 54° and 57° F. The loss of oil was 2 gallons per ton of ore. A concentration of 14:1 was achieved with a recovery (in the concentrate) of 69% of the gold, 65% of the silver, and 70% of the copper from a pyritic and chalcopyritic ore assaying 1.12% copper, 0.049 oz. gold, and 0.8 oz. silver per long ton. The process was described as "a somewhat dirty and nasty process." It did not work on oxidized or earthy ores, nor upon tarnished sulphides.

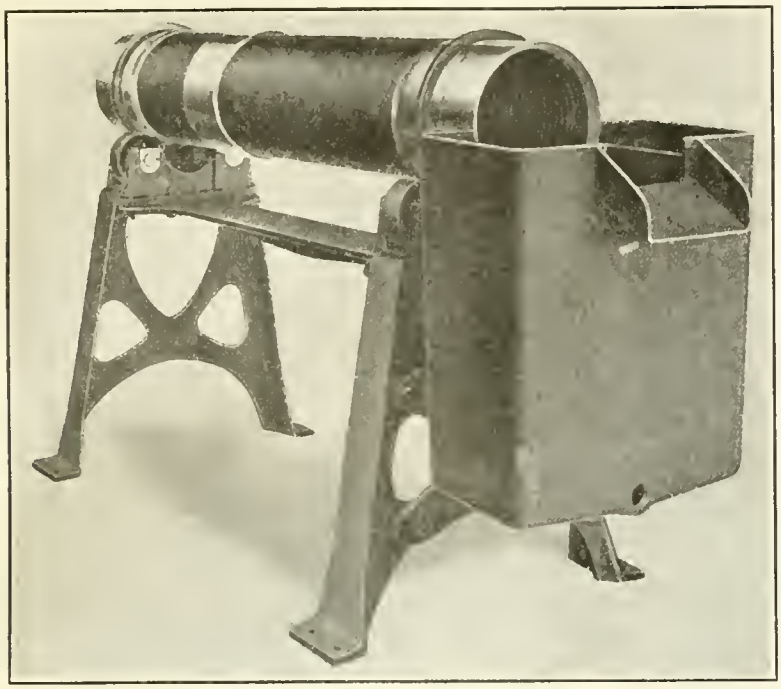

FIG. 3. THE MACQUISTEN TUBE.

In the course of the discussion following the reading of the paper by Mr. Rolker from which these facts are gleaned, it was acknowledged that the process developed by Mr. Elmore was based on previous experimental work done, at the same mine, by George Robson, who used petroleum in even larger proportion, as much—I have been informed—as three tons of oil to one of ore. But the most interesting fact elicited by the discussion was the statement made by Mr. Elmore, and confirmed by the superintendent of the mill, John Bevan, that the actual load of mineral on the oil was 25%, as against the theoretical load of 10% inferred by Mr. Rolker. In short, the oil did 150% more than anybody could explain. The 'prior art' was in the dark, but the posthumous art of today can make a confident guess. Of course, the larger part of the levitation was done by air, entangled previously in the ore particles or entrained subsequently during the mixing of the pulp with the oil in the drum. Later investigators can testify how difficult it is to prevent the indrawing of air under such circumstances. Therefore even in this beginning of flotation as a practical process the agency of air was utilized, although unwittingly. Four years later Walter McDermott, who has been a consistent supporter of the Elmore brothers in their flotation business, acknowledged that "the agitation with the pulp results in the oil taking up a very appreciable quantity of air."[7]

This fact was not recognized at first, but in 1904, six years after the first bulk-oil patent of 1898, Francis E. Elmore took out his patent for vacuum-oil flotation. See Fig. 8. In this he subjected the oiled and acidulated pulp to a vacuum, thereby releasing the air dissolved in the water. The air thus held in solution amounts to 2.2% by volume, at sea-level and 60° F. By

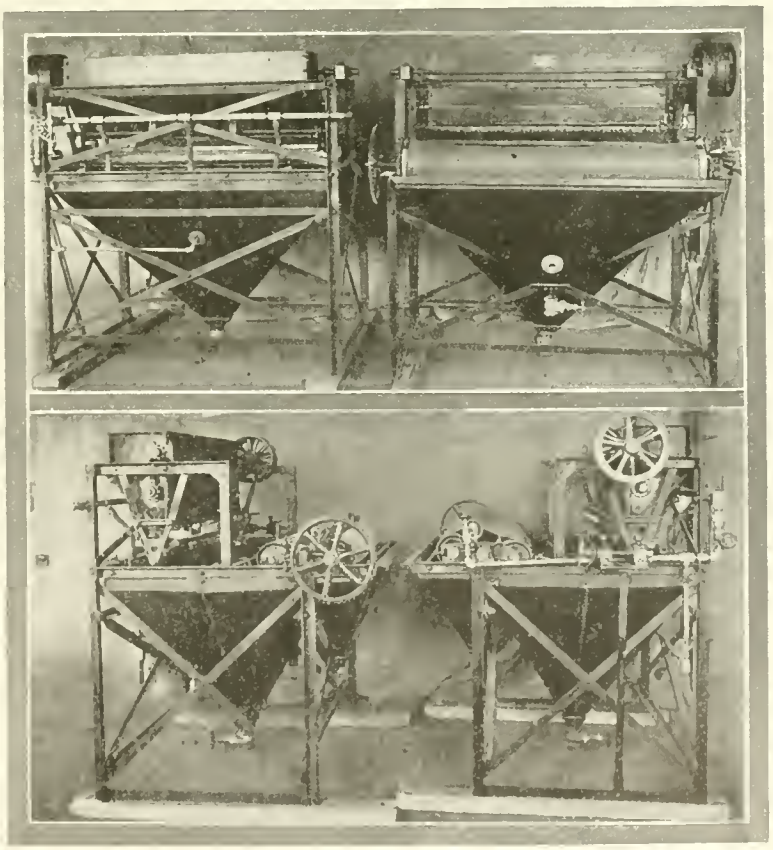

FIG. 4. THE WOOD MACHINE.

[7] "The Concentration of Ores by Oil." *E. & M. J.*, February 14, 1903, page 262.

lowering the pressure and raising the temperature this air is released, thereupon attaching itself, in the form of bubbles, to the oiled sulphide particles, which rise to the surface. For example, the air in a pulp of 1 ton of ore to 6 of water suffices to lift 360 lb. of zinc-lead sulphides in a Broken Hill ore.[8] In actual practice, however, the weight of sulphides floated is considerably greater than the theoretical capacity, as based on the efficacy of the air released from solution in the water. Part of the work is done by the gaseous carbon dioxide liberated by the reaction between the acid and the carbonates, such as calcite, either in the gangue or added in the form of limestone. Part of it is entangled in the ore particles and part of it is entrained into the pulp during mixing. In this process the quantity of oil added to the pulp was reduced to 10 lb. per ton and finally, in some cases, to as little as 3 lb. per ton of ore. The machine devised by Elmore was remarkably ingenious and to it the success of the process was largely due. It was applied at many mines, notably the Sulitelma copper mine, in Norway.[9]

The Potter-Delprat and the Elmore vacuum processes are clearly based on the activity of bubbles of carbon dioxide or air, or both. Next, mention must be made of Alcide Froment, who, although he was not the inventor of a working process, introduced the idea of violent agitation for the purpose of producing bubbles of gas rapidly from a pulp containing both calcite and acid. While he looked to carbon dioxide as the gas from which to make his bubbles, he did undoubtedly entrain lots of air and obtained the use of it in generating the bubbles that attached themselves to the oiled particles. He did not recommend much oil: only "a thin layer." In his later instructions to the Minerals Separation company, which bought his British patent in 1903, he specified that the oil was to be from 1 to 3½% on the ore.

The next method was that invented by Arthur E. Cattermole, also in 1902. It was to buy his patents that the Minerals Separation company was organized in 1903 by John Ballot, J. H. Curle, W. W. Webster, S. Gregory, H. L. Sulman, and H. F. K. Picard. Cattermole departed from the prior art. Instead of floating the sulphides, he sank them, while the gangue was assisted to rise in an upward current of water. He added oil in the proportion of 4 to 6% "of the weight of metalliferous mineral present in the ore," together with 2% of soap, so as to obtain an agglomeration of flocculent sulphide particles, which, being heavily oiled, stuck to each other, in groups or granules that sank to the bottom. He used a Gabbett,[10] or cone-mixer, to obtain a violent agitation of the pulp, and followed it by a gentler stirring during which the separation into "shotty granules" was effected in the presence of as little air as possible.

This process was only put to work in one mill, on the Central mine at Broken Hill, where it must have seemed a metallurgical abortion during the very short time it was in use. The oil was emulsified with soft soap and then fed into the mixers, where the crushed ore underwent agitation with acidulated water. From the very start a considerable proportion of mineral was floated on the froth incidental to violent mixing in the presence of air. Apparently only a part of the sulphides was 'granulated,' so as to sink according to program. The remainder was floated unintentionally. The description given by the manager, James Hebbard, indicates that he and his staff stumbled upon the so-called agitation-froth process almost immediately. He records[11] how he discovered that more froth was made by using less oil, and that the frothing and floating proved a better method than the granulating and sinking of the sulphide particles. He also states that the discovery was made concurrently by the metallurgist[12] of the Minerals Separation company in the London laboratory. They hit upon the same idea by varying the quantity of oil, in March 1905, so we are told. Yet the plant at the Central mine was allowed to start on the Cattermole process in July. Successful tests with the frothing process were not made until September, the proportion of oil being reduced from 3% when granulating to between 0.15 and 0.2% when frothing. The plant was gradually changed until granulation was completely ousted, by decreasing the quantity of oil and increasing the violence of agitation. The ore from the mixers was passed with "a good splash" into spitzkasten, thereby accentuating the need for aeration.

So the failure of the Cattermole method is stated to have led to the Minerals Separation process of today, the proprietary rights to which are based primarily on U. S. patent No. 835,120, dated May 29, 1905. This is a process "wherein, by the use of a frothing agent, and in the presence of such agitation as will maintain or produce distribution of the ore particles through the pulp, and dissemination of bubbles of air through the pulp and into contact with the metallic particles through the pulp, the air bubbles will seize the metallic particles and will carry them to and through the surface of the pulp, so as to permit of their delivery at or above the surface of the pulp separate from the gangue particles." This description is taken from the complainant's brief in the suit of Minerals Separation, Limited, *v.* Miami Copper Company, 1915. It is further explained that in this process "the frothing agent is an oil or immiscible liquid, and the discovery was that this mode of operation in the concentration of ores was attainable with small quantities of oil, quantities so small that although the oil coated the metallic particles in the exercise of the well known preferential affinity of oils for metallic substances, the coating was so minute, so nearly infinitesimal, that the oil disappeared from sight and sense. In this process the oil coats the metallic particles, modifies

the water so as to produce minute and persistent air-bubbles, and increases the attraction of the metallic particles for the air-bubbles; and the persistency of the air-bubbles is such that the air-bubbles cling to the metallic particles and carry them to and through the surface of the pulp, and when the air-bubbles escape from their water environment in the body of the pulp and are exposed at or above the surface of the pulp, their water-

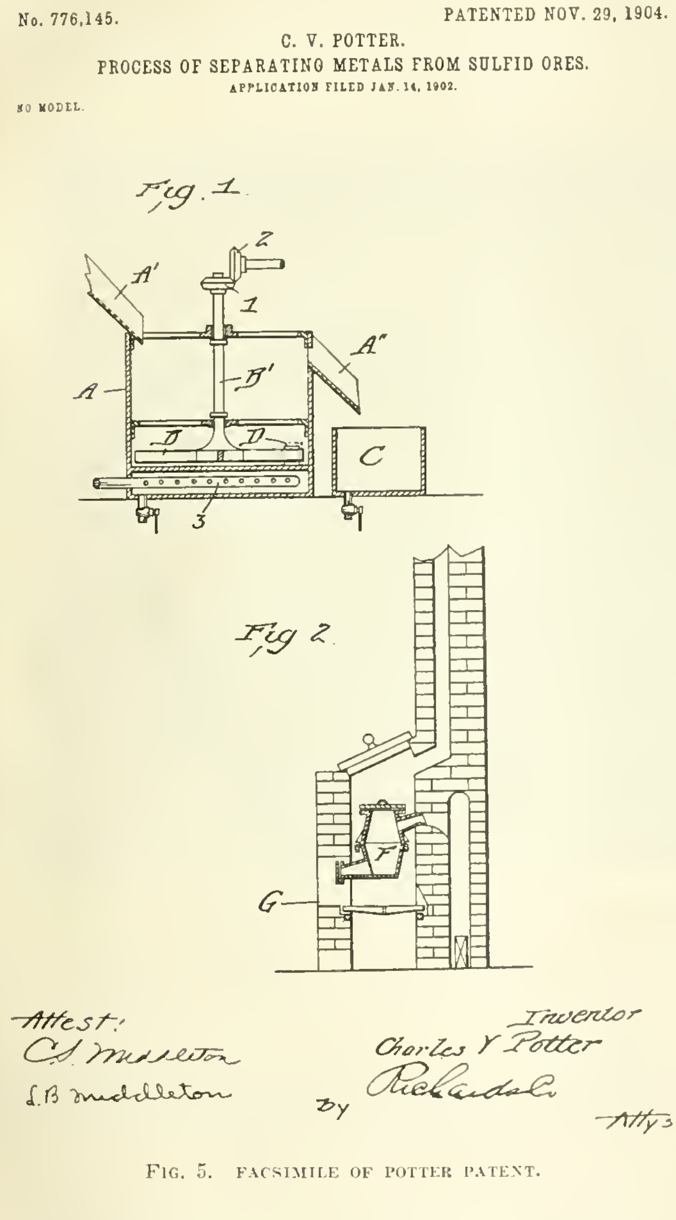

FIG. 5. FACSIMILE OF POTTER PATENT.

films carrying a mineral load are maintained intact until at least their separation from the body of the pulp has been effected, by overflowing or otherwise. The air-bubbles with their mineral load form a froth floating upon the surface of the pulp, which, if allowed to remain there in a quiescent condition will float for days and weeks. This froth has therefore been properly called a persistent or permanent froth. It will always form a coherent mass of bubbles pressed against each other and frequently several inches in thickness.''

This description, lacking adequate punctuation, as is usual in legal statements, may be accepted as official, being the product of a joint effort on the part of counsel and experts representing Minerals Separation in the lawsuit at Wilmington. In the basic patent, No. 835,120, the proportion of oil is given as ''a fraction of 1% on the ore.'' W. H. Ballantyne, patent lawyer for Minerals Separation, testified, in the Hyde suit, that ''an ideal standard for the agitation-froth process is $1\frac{1}{2}$ to 2 lb. oil per ton of ore.'' Much less is used now in the big mills of the copper mining companies.

The process was first introduced on a working scale

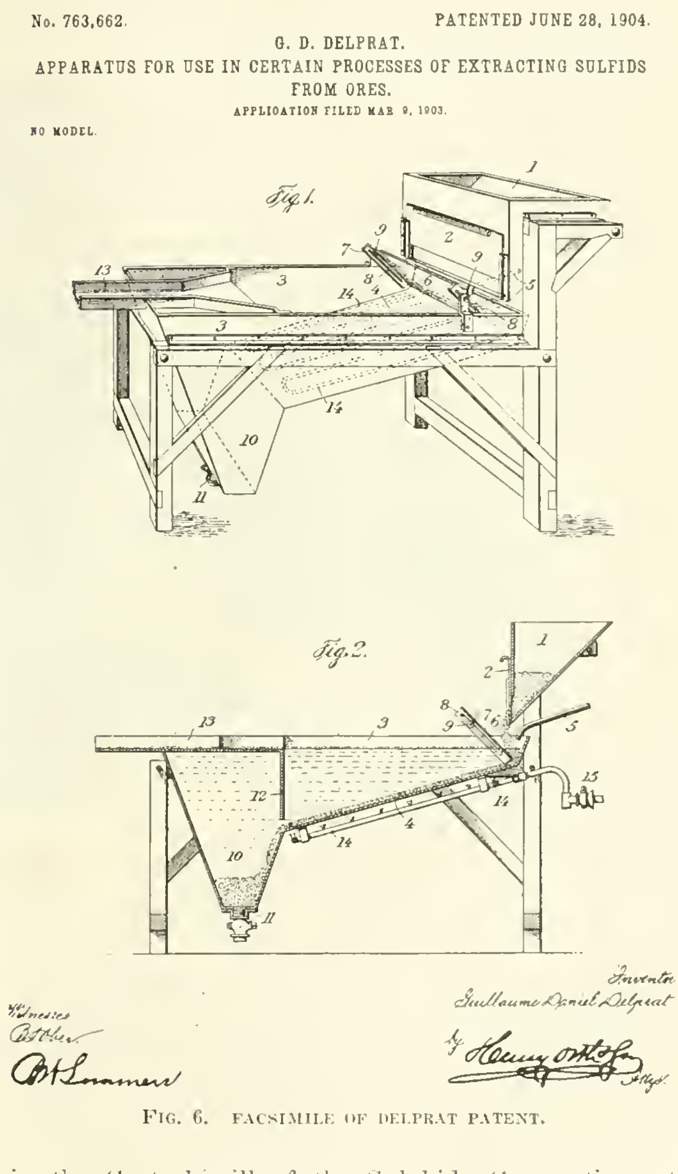

FIG. 6. FACSIMILE OF DELPRAT PATENT.

in the Central mill of the Sulphide Corporation, at Broken Hill, as already mentioned. Two years later, in 1907, it was adopted by the Zinc Corporation, to be discarded during 1909 in favor of the Elmore vacuum process, and to be restored again to favor in 1911. See Fig. 9.

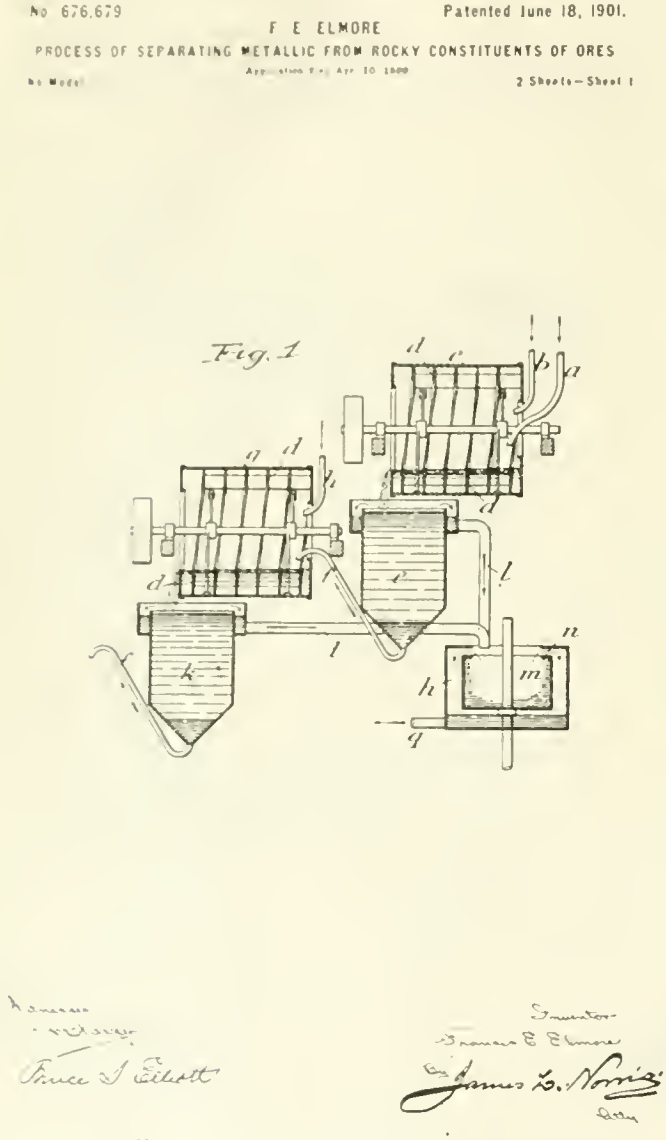
The next important application was made in 1912 at the Braden Copper mine, in Chile, where a 200-ton plant was erected. The extraction of copper (as concentrate) was 80 to 85%. But when a larger mill of two 600-ton units was built the recovery became poor, being no better than it had been in the old water-concentration mill.

namely, about 65%. Whereupon the oil was added to the ore in the tube-mill and the extraction improved at once. The mill has now been enlarged to seven 600-ton units, treating 3500 tons per day.[13] The extraction last year was 77 per cent.

In February 1915 the Anaconda Copper Mining Company took a license from Minerals Separation, and at that time also the Inspiration Consolidated Copper Company made an agreement for the same purpose. Both companies built large mills for the operation of the process during last year.[14] The Anaconda now treats 12,000 tons and the Inspiration 10,000 tons of ore daily by flotation.

The first mining company in America to ignore the Minerals Separation patents was the Butte & Superior, in Montana. Under the technical guidance of James M. Hyde, this company built a 150-ton unit in their mill during 1912. This provoked the first test case,[15] which is now before the Supreme Court of the United States.

Other companies charged with infringement are the Utah Copper, Nevada Consolidated, Magma Copper, and the Miami. The first three use the Janney machine and the last one the Callow pneumatic launder. In each case it is stated that the Minerals Separation machine—in which violent agitation is effected by blade-impellers—was tried first and then discarded as ineffective. The pneumatic flotation plant at Miami was commenced in August 1914 and remodeled in the early part of 1915. Suit for infringement was brought at once by Minerals Separation, the trial commencing on March 29 and end-



No 676,679 Patented June 18, 1901.

F. E. ELMORE

PROCESS OF SEPARATING METALLIC FROM ROCKY CONSTITUENTS OF ORES

Application filed Apr. 10, 1900. 2 Sheets—Sheet 1.

ing on May 27, 1915. The decision of the Court is not yet known.

As applied at Miami the flotation process is simplified by the use of a launder having a canvas bottom through which air is forced under pressure. This gives the gas required for the generation of bubbles in a pulp previously modified by the addition of oil, which is mixed with the ore while being pumped into a Pachuca tank, or Brown agitator, where it undergoes further emulsification before entering the Callow launder constituting the flotation-cell. It is claimed that the froth produced in this way is different from that made in the mechanical

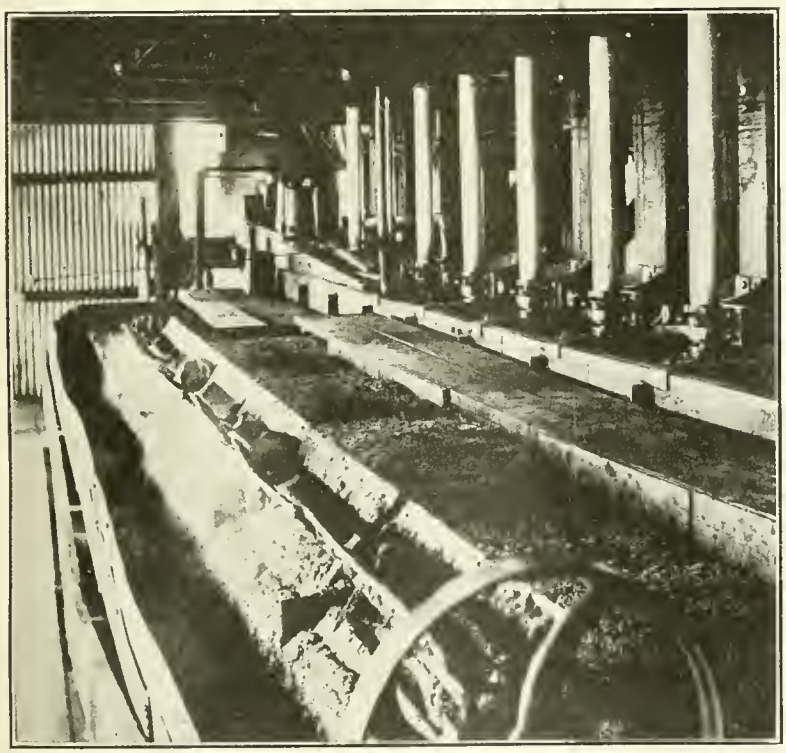

FIG. 9. FROTHING PROCESS IN THE CENTRAL MILL, AT BROKEN HILL.

mixer of the Minerals Separation machine. In the one case, according to R. C. Canby, the froth consists of a mass of delicate, fragile, and evanescent bubbles, which rise to the surface in rapid succession and maintain a froth only because they are being generated slightly faster than they break, so that the uppermost layer overflows, with its burden of mineral, over the lip of the vessel. In the other case the froth is said to be "thick, coherent, and persistent," as Mr. Picard phrased it. "It appears as if the minerals were protecting the tender air-bubble like an armor, and instead of destroying it, were actually guarding it. The froth has a long life. I have myself seen a froth standing for 24 hours without the least change having taken place." So testified Dr. Adolf Liebmann. Mr. Ballantyne stated that this agitation-froth of the Minerals Separation machine was so dense that it would support a spade. Mr. Canby showed that the air-froth of the Callow machine would not support a match-stem.

From the foregoing summary it is clear that three processes are covered by the general term 'flotation,' and that to clarify the discussion of the subject it will be well to distinguish between

1. Film-suspension, as in the Wood and Macquisten methods.

2. Oil-flotation, as in the Robson and Elmore bulk-oil methods.

3. Bubble-levitation, as in the Elmore vacuum, Delprat, Froment, and Sulman-Picard methods.

The third class can be further sub-divided according as carbon dioxide or air is the principal gas utilized for making bubbles.

Finally, the air-bubble method can be classified according to the way in which the air is introduced:

(1) From the bottom of the vessel, as in the Callow and Owen cells.

(2) By being entrained or dragged into the pulp by the beating of paddles or some other form of impeller, as in the Gabbett and Hoover mixers.

(3) By escape from solution in water, as in the Elmore vacuum machine and the Norris apparatus.

It remains to emphasize the fact that from the high ratio of 3 tons of oil per ton of ore, the proportion of oil used in flotation has decreased, by reason of the recognition of the part played by air, to one-third of a pound per ton of ore; that is, one eighteen-thousandths of the quantity used by Robson. Concurrently the acid used has decreased to a minus quantity, namely, alkalinity.

MINE-CARS at the Copper Queen mine, as first designed for the underground electric haulage system, held 21 cu. ft., had gable bottoms, hinged sides, and were equipped with M.C.B. midget couplers, spring-draft rigging, and roller-bearing axles. This car was found not satisfactory. The ore was too sticky to slide well, requiring rocking by the men to empty the cars. Also the cars leaked fine ore when wet. Later, roller-dump cars, weighing 1700 lb. and of 33 cu. ft. capacity, were secured. These also had the refinements of spring-draft rigging, automatic couplers, and roller bearings. However, instead of the solid bearings used on the first cars, the axles were designed to take Hyatt rollers with special care to make them dirt-proof. Roller-bearing axles have been an unqualified success; the axles are filled with grease only once a month. The Hyatt-bearing axles last at least six years, and the recent chrome-nickel steel types wear longer yet. It is well to use large cars underground to reduce the cost of loading, dumping, and repairs. On the other hand, narrow drifts cannot accommodate wide cars, and for convenience in taking cars from one level to another by the cage, it is necessary to limit the size. Thus the underground cars at Anaconda are less than one ton capacity.

Slime-Settling

*The desirability of correlating the data obtained from small-scale slime-settling tests with commercial work as carried on in large tanks has long been recognized by metallurgists. This need, though most apparent in designing new installations, frequently arises also in existent plants, since a large range of experimental work can be performed without interfering with regular operation.

In order to develop rational methods of laboratory testing, it becomes necessary to study the general phenomena of settling. In milling, slime-pulp consists of water, finely-divided sand or granular products, and colloidal matter. In this connection water is used as implying either ordinary water, or water containing some chemical or chemicals in solution. Those which exert an influence upon the subsequent settling behavior of the pulp, are known as electrolytes. The electrolyte has the property of causing the colloidal portion of the slime to form aggregates known as flocs, particles having a more or less definite size, consisting of water, colloidal material and usually fine-granular matter that has been entrapped. The flocs settle in the liquid medium according to certain laws. There are four settling zones, (1) the bottom, where that portion of the pulp wherein the flocs, considered as integral bodies, have settled to a point where they rest directly one upon another; (2) a transition zone above the bottom one; (3) pulp of constant consistence of flocculated pulp and of the same consistence as the flocculated pulp in the feed pulp; and (4) the top zone of clear water or solution.

The authors summarize their investigation as follows:

(1) In thickening pulps which are to be discharged at a consistence such that the discharge is still in the form of free-settling pulp, the depth of the tank used is of no consequence, except in so far as it permits a depth of feed sufficient to avoid surface agitation and allows ample depth of clear liquid to care for fluctuations of the feed, and changes in the character of the pulp in the case of continuous thickeners, and sufficient depth to give ample capacity to avoid the necessity of frequent charging and discharging in the case of intermittent thickeners.

(2) When thickening pulps to a consistence where it is necessary to expel fluid by compression, sufficient capacity must be given the tank so that the pulp will be retained the necessary period of time to thicken it to the required density and also to allow sufficient storage to compensate for fluctuations in the feed and discharge. This capacity may be obtained by varying either the depth or diameter to give the required cubical content.

(3) The consistence of discharge possible may be closely determined by allowing a cylinder of thick but free-settling pulp to settle, taking readings at intervals of a few hours up to the point where settling practically ceases.

(4) The required area may be computed by applying the formula $A = \frac{2,000}{24\left(\frac{62.35R}{F-D}\right)}$. A is the area in square feet required to thicken 1 ton of 2000 lb. of solids to a consistence in the discharge of D (parts fluid to 1 part solid by weight), per day of 24 hours. A series of settling-rates is taken on pulps ranging in consistencies from that of the proposed feed to the thickest free-settling pulp. D is taken as the ratio of fluid to solids in the thickest pulp which can be economically obtained. The greatest value for A indicated by the tests is taken as the required area. Under ordinary circumstances a factor of safety should be allowed over the calculated area to take care of changes in the character of the pulp and variations in temperature. It will be noted that this is the same formula previously given, modified to give area required instead of capacity per square foot per hour.

(5) The required depth of the thickener may be ascertained by computing the capacity of the thickening zone to contain a supply of solids equal to the total capacity of the tank for the number of hours required to thicken the pulp to the density required in the discharge, and to this depth adding an allowance for the lost space due to the pitch of the drag in the thickener; also from 1½ to 2½ ft. for depth of feed, and a further allowance for storage-capacity when the discharge may be closed.

The following table gives the actual capacities, together with the computed capacities, of thickeners used at the various mills enumerated. In each case the tests were made at the mill by the local staff, according to directions supplied by the authors. From the data received the capacities were computed, employing the method described.

PULP	Computed capacity, lb. per sq. ft.	Actual reported capacity, lb. per sq. ft	No. of ft. clear solution reported	Consistence of feed-pulp	Consistence of discharge-pulp
Liberty Bell	4.87	5.94	1.25	10.00–1	2.00–1

*Some colloidal material in this pulp had a tendency to remain in suspension after most of the pulp had settled. The thickener was operated below capacity.

†Thickeners being operated below capacity.

*Abstract from a paper by H. S. Coe and G. H. Clevenger, prepared for the Arizona (September 1916) meeting of the American Institute of Mining Engineers.

TAXATION of Michigan copper mines has been overdone. Homer Guck points out that the Ford Motor Co., one of the manufacturing concerns of the lower peninsula, earns more money than all the Lake Superior copper mines combined.

Mining in Utah

By L. O. Howard

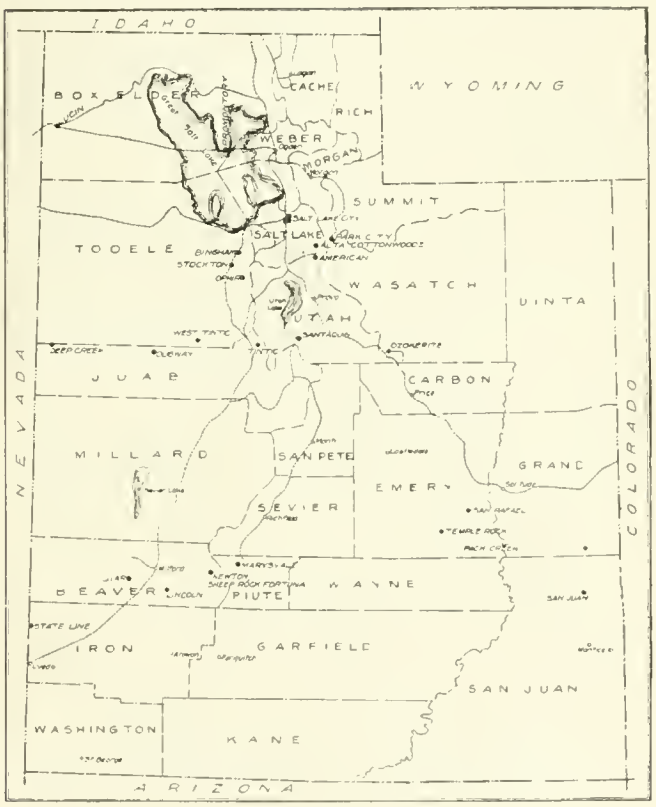
THE volume of trading on the local stock exchange has not been so great since 1909. During February there was transferred 4,591,950 shares worth $888,471. Tintic stocks have always been good counters for gambling. Their erratic orebodies, coupled with the peculiar habit of most of the Tintic mines of distributing their profits promptly in dividends, has made the stocks highly speculative. Assessments and dividends alternate. Repeated 'come-backs' have done much to popularize the cheap stocks, so that all but the largest flotations are based on 5 and 10-cent shares. The length of the calls has been increased and after April 1 unlisted stocks are to be absolutely ignored by exchange brokers.

A decision just rendered by the Commissioner General of the Land Office at Washington in the case of the U. S. Forestry Service *v.* The Kennebec Mining Co., is interesting. The Kennebec was engaged in driving an adit to apply as patent work on its Cottonwood property. The Forest Service took it upon itself to intervene, on the ground that the proposed work would not be upon the claims to be patented, and if continued would be of no benefit to them. The company announced its intention of changing the direction of the adit, and upon this defense was upheld in the local Land Office. The Forestry Service was not satisfied, and appealed to Washington. The mining company was again upheld. The Forest Service has gained nothing but further ill-will, and laid itself open to renewed charges of obstructing legitimate mining.

In the Cottonwood district parties connected with the Maxfield mine are to develop a large area of granodiorite at the head of Little Cottonwood. On the claim-maps of the district this area has remained a blank, because it was thought there was no limestone or other conditions favorable to ore. It is now claimed that there is limestone in this area. If so, it is an attractive prospect. Rumors are plentiful in regard to railways for the Cottonwoods. A franchise is being sought for an electric railway up Big Cottonwood.

Development continues in the American Fork district just over the divide from Little Cottonwood. Among the companies engaged in mining or soon to start work are the Texan, Pacific, Miller Hill, Globe Con., Earl-Eagle, Mineral Flat, Smuggler, Pittsburg, Bay State, Treasure Con., Major Evans, Whirlwind, Dutchman, Boyd Park, Deer Creek, Eudora, Bogg, Wasatch Range, Live Yankee, American Fork, Mary Ellen, Belorophen, Phoenix, American Volunteer, Bredemeyer, South Park, Mountain Lake Extension, Silver Flat, and Tonto Development. Geologically the district lies on the strike of the productive formations of the Cottonwoods. A power-line is to be extended into the district and at least one mill is planned.

Shipments from Park City decreased in February, owing to the short month and bad climatic conditions. Eleven shippers sent out 6564 tons. They were the Silver King Coalition, Daly-Judge, Daly West, Silver King Consolidated, Ontario, Federal Leasing, Broadwater Mills, Big Four Exploration, Western Ore Purchasing, and Quiney. The Daly West mill, which has been shut-down owing to lack of water, will be started



MAP OF UTAH.

soon. The heavy snow-fall assures plenty of water during the summer. Development is progressing favorably at the Keystone, New Quincy, Three Kings Silver, and American Flag.

Shipments from Tintic in February were increased to 24,550 tons of a gross value of $610,000. There were 25 shippers, the Eureka Hill, Godiva, and Black Jack resuming their places in the list. The Crown Point and Plutus are two old mines on which work is to be renewed owing to the present favorable conditions. Two new incorporations have been launched to mine in northeast Tintic, in the part of the district that has been proved by the Chief Consolidated. They are the North Tintic Mining & Milling Co. and the Chief Consolidated

Extension. One of the principal causes of the boom in Tintic stocks is the development of a large body of copper ore in the Iron Blossom mine. Ore assaying 16% is being broken on the 1000-ft. level. A cross-cut 85 ft. long has not reached the limit of the ore at this level. Another cheerful discovery is the $80 gold ore in the Gold Chain mine.

The crushers and roasting-furnaces have been started at the new mill erected by the Knight-Dern interests. Last summer the chlorination plant at Park City was closed and operations transferred to Tintic. Two Holt-Dern furnaces are roasting 90 tons per day. When all are in commission, 3 Holt-Dern and 1 Knight-Christensen furnaces will be used. Capacity is estimated at 300 tons per day. Briefly the process consists of crushing by rock-breaker and rolls to ¾-in., feeding automatically the proper mixture of ore, salt, coal, and sulphides to the furnaces, in which a chloridizing roast is accomplished, and further chloridizing in bins, after which the calcined material is leached in brine and acid solutions for the recovery of gold, silver, lead, and copper. These metals are recovered by successive precipitation on copper and iron.

Bingham, best known for its low-grade copper, now claims the distinction of having the largest shipper of lead ore in the United States. The mine is the Utah-Apex. The company has a contract to ship 300 tons of lead-zinc ore per day to the United States smelter, in addition to the 300 to 400 tons it is shipping to the American Smelting & Refining Co. The Utah Metal-Bingham-New Haven reports for 1915 show that this consolidation produced 2,873,815 lb. copper, 9,860,089 lb. lead, 16,914 oz. gold, and 475,894 oz. silver, for a net profit of $594,295. The profit for January this year was $125,000. Another dividend-payer is thus assured for Bingham. Utah Copper is now paying $2.50 per share quarterly. Bad weather reduced the output in January to about 12,000,000 lb. copper, compared with 14,500,000 lb. in December. The Bingham Mines Co. plans extensive development of the Yosemite mine. Its report for 1915 shows a net income of nearly $200,000, half of which came from the operation of the Eagle & Blue Bell mine at Tintic.

In Beaver county the scale of operations is increasing. In addition to the companies that I mentioned last month, the following are becoming active: Indian Queen, near the Horn Silver; Monzonite Silver & Gold, adjoining the Cedar-Talisman; Galena, in the Beaver Lake district; and Master Key in the Star district. New discoveries are being made in the Fortuna district. At the Gold Hill, adjoining the Sheep Rock, ore is being developed by an adit, on a vein that panned well at the surface. It is said that high-grade has also been opened for 40 ft. along the vein, and 5 to 6 ft. wide. The United States shaft has penetrated milling ore, and a cross-cut at 85 ft. is reported to have cut ore that can be shipped at a profit. Operations were later suspended. No reasons were given, but it may be surmised that the company is now endeavoring to secure control of surrounding ground. The Sheep Rock has been bonded by local interests. A deposit of alunite occurs on this property. The local press announced the intention of the new management to erect a mill to treat this for its potash. This must be taken with reserve, seeing that the recent investigation of the newer discoveries of alunite at Marysvale resulted in the conclusion that they were not of commercial value.

There is talk that operations may be resumed on the Sacramento at Mercur. This is one of the old producers, which was unique as being the only one to operate a mercury-distilling plant. The company treated 300,000 tons of gold ore by cyanidation and paid $308,000 in dividends. The ore yielded about $3 per ton near the end of operations, and the tailing carried another dollar per ton. Operations covered a period from 1895 to 1907. During the five years 1903 to 1907 the company produced 3538 flasks of mercury, worth about $139,000. There was recovered 102 lb. of mercury per ton of ore at a cost of 10.18 cents per pound. The revival, if it is to come, will be in the mining of gold ore. On the west dip of the Mercur district the group about the old Daisy is now in strong hands. The property is equipped with a cyanide plant. The mines have had a checkered history. The last attempt to work them was in 1913, when the Norma Gold Mining Co. re-modeled the cyanide plant, and ran it a short time. The treatment consisted of separate leaching of sand and slime, and filtration of the slime on Moore filters. The operation was not successful, but it is believed that with ample capital there is a good chance of doing well.

The distribution of a dividend of $15,000 on March 6 by the Lakeview Mining Co. of Promontory brings the total for the first year of operation to $100,000. Fifteen cars of ore containing 32.5% zinc were shipped in February. Ore has been opened by lessees 3500 ft. north of the main workings. Some lead ore also is being shipped. The Promontory Development Co. has opened a 6-ft. vein of low-grade zinc ore. Some ore of shipping grade has accumulated on the dump.

There are substantial rumors that the American Smelting & Refining Co. intends to erect an electrolytic zinc plant. The proposed sulphuric acid plant at Garfield and the success of the electrolytic plant at Murray (2 tons per day) are known facts. Cheap power and a large ore-supply are two other factors. A plant for extracting zinc has long been desired by producers. Large reserves of ore at Tintic, Bingham, Park City, and smaller amounts at Ophir, Stockton, the Cottonwoods, Promontory, and in Beaver county, would become profitable if the high freight-rate to the East were avoided. Further efforts along the same line are indicated in the announcement just made by the Daly-Judge Mining Co. that it intends to erect a plant for roasting and leaching zinc ore, and electrolyzing the solutions. With power developed by the Snake Creek tunnel and a large supply of zinc ore from its own mine, the outlook is good. It is planned to build a plant in or near Park City large enough to take care of all the Daly-Judge zinc ore.

CONCENTRATES

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

LEAKS in compressed-air lines are more costly than leaks of the same size in steam lines.

SOME of the rarer minerals occur irregularly in the granitic pegmatites of southern California.

WORN-OUT mine car-wheels, with the axles sawed-off, then clamped to the inside of tube-mills and set with cement, are being used on the Rand for liners.

TIGHT KEYS in pulleys may be removed by placing a teaspoonful of 40% dynamite against the end of the keys, mud-capping the charge, and exploding it.

MINE-PUMPING figures are expressed both in millions of gallons per day and in hundreds of gallons per minute. A million gallons per 24 hours is about equal to 700 gallons per minute.

ARSENO-PYRITE when it is struck with a hammer gives off an odor somewhat like garlic—the 'alliaceous odor' of the text-books—an odor familiar in mines where drills are cutting rock or ore impregnated with arseno-pyrite.

FIREMEN'S WHISTLES are considered better warning signals than motor bells at the Leonard mine at Butte, where crossings over electric-haulage tracks underground are dangerous on account of the difficulty of seeing an approaching train from cross-cuts or drifts that cross or join the haulage-level.

THE H-BIT, says a mine-superintendent who has used it for several months, drills best when the little cross-bar of the H is left off. The effect of the double cutting-edge without the cross-bar is to chip the rock in the centre of the drill-hole in larger fragments by reason of the rotation of the two off-set cutting-edges.

THE TROY POUND contains 5760 grains; the avoirdupois pound 7000 grains. As there are but 12 ounces in a troy pound, each troy ounce contains 480 grains and is heavier than an avoirdupois ounce, which, being $\frac{1}{16}$ of a pound, contains 437½ grains. That is, a troy ounce of gold is 9.7% heavier than an avoirdupois ounce.

ELECTRIC-ORE HAULAGE underground in the Copper Queen mine cost 23c. per ton in 1914, the average distance trammed being 2939 ft. Of this cost, 11c. was for labor; 7.4c. was for maintenance of motors, cars, trolley, and tracks; and 1.3c. was for power. Cost of car repairs was high as the equipment was several years old.

VANADIUM MINERALS, more especially those of the oxidized zone, are readily soluble in mineral acids. Hydrochloric is the most convenient acid to use. If concentrated hydrochloric acid, HCl, is put upon carnotite, uvanite, vanadinite, the descloizites, and some other vanadium minerals, it immediately gives a rich red-brown solution. If water is added the color changes to green or disappears.

LUBRICANTS sometimes contain corroding substances, and should be tested for these. A simple method is to polish a steel surface, coat it with the lubricant, and expose it to the sunlight for 15 to 20 days. If acid is present in the lubricant the steel will show etchings. Water oxidizes the steel and shows rust pittings, the latter showing better on a rough surface.

MICA is used considerably in electrical machinery, as an insulator between the segments of commutators, the soft grades being preferred. The General Electric Co. formerly obtained mica from its own mine near Sydenham, Ontario. Large sheets of mica bring a high price for lamp-chimneys and novelties. Scrap mica is ground fine for fire-proofing materials and miscellaneous uses. Quebec produces a good deal of mica mined in irregular amounts from Pre-cambrian crystalline rocks by prospectors. London has been a large market for mica, where lots were sold by auction so that the buyer could see exactly what he was getting.

MAINTENANCE COST of electric centrifugal pumps compared with steam pumps at a mine of the Penn Iron Mining Co., Michigan, for one year was as follows:

	Four centrifugal pumps.	Four steam pumps.
Shop labor	$717	$760
Labor on pumps	690	590
Supplies	503	2021
Total	$1910	$3371

These two sets of pumps were doing practically the same duty.

TIN. The simplest test for cassiterite is to place a fragment of the mineral in dilute hydrochloric or sulphuric acid with granulated, shot, or sheet zinc. The zinc and the acid rapidly evolve hydrogen, which takes the oxygen from the mineral and leaves a coating of tin on the fragment tested. Granulated zinc is the best to use. The blow-pipe test is better known and is more often used, though it is not made so readily. The mineral supposed to be cassiterite is pulverized and should yield a light-colored powder unless it is mixed with iron oxides, in which case the powder will be reddish or brown. Some cassiterites from the Carolinas and South Dakota, however, give a purplish powder. A small portion of the powder is mixed with twice its bulk of pulverized charcoal and three times its bulk of sodium carbonate or bicarbonate (ordinary washing or baking soda). The three substances are thoroughly mixed, and a portion the size of a pea is moistened and placed in a hollow in a piece of charcoal. By means of a reducing blow-pipe flame tin is readily reduced in small globules, which are easily distinguished from the flux.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

SANTA FE, NEW MEXICO

MINERAL PRODUCTION OF THE STATE MADE PUBLIC BY OPERATION OF NEW TAX-LAW.

For the first time in the history of mining in this State, authoritative figures on mineral production have been secured. The State Tax Commission, working under the provisions of the Springer-Hawkins mine-tax law, passed last year, is responsible for these data. The gross production of New Mexico's coal and metal mines in the calendar year 1915 was nearly $22,000,000, with $10,000,000 net. One concern, the Chino Copper Co., produced more than half of the entire gross, or $11,383,777, with $6,846,204 net. This company is treating 7500 tons of 2.1% ore per day.

The Commission's figures cover 36 coal and metal-mining enterprises. In addition to these, the Colorado Fuel & Iron Co., and the Ozark Mining & Smelting Co., also were producers in 1915, but their returns are not yet complete. The figures on gross production are those returned to the Commission by the operators, but the net values, on which taxes are collected, were determined after an examination not only of the returns made, but of reports submitted by a special accountant who checked the operators' books. The gross production returned by the 36 producers was $21,695,479, and the total net, as determined by the Commission, $9,824,736.

The 10 coal enterprises of New Mexico, now on a producing basis, returned a total output in 1915 of $6,674,590, and $1,397,734 net. Among the coal concerns, the Stag Canyon Fuel Co. (Phelps, Dodge) ranks first in gross production, and the St. Louis, Rocky Mountain & Pacific Co. second, but in net production their positions are reversed.

Among the metal-mining concerns, the gross output of the Eighty-five Mining Co. is second to that of the Chino, but the Empire Zinc Co., operating in both Grant and Socorro counties, has second place in net output, showing $457,114 net out of a gross of $534,579.

Under the provisions of the Springer-Hawkins law, the mines and mineral lands of the State are divided into productive and non-productive classes. On the net outputs of the producing properties taxes are assessed as on all other property, and these taxes are considered to cover the full mineral values of the lands being worked, and of contiguous mineral lands held for future extensions of mining operations. The net value of the mineral output is stated to mean the difference between the actual cost of production, transportation, treatment, shipment and sale, and the amount realized, if sold, or that could be realized at the time of making the reports, and it is specified that the statements of expenditures shall not include any amounts expended for machinery or other improvements, for the construction of mills or other reduction-works, or for salaries of persons not actually engaged in the working of the mines, in the reduction, transportation or marketing of the minerals, or in the personal management of the enterprises. All non-productive mineral lands are to be assessed and taxed on the reasonable valuation thereof as undeveloped mineral ground, in addition to their surface values for grazing, agriculture, timber or other purposes, and in fixing such values it is the duty of the taxing officials to take into consideration transportation problems and opportunities for marketing the products. The law does not exempt from taxation reduction-works, buildings and other improvements at mines or on mineral lands.

In Socorro county, the Mogollon Mines Co.'s gross yield was $508,502, and $134,485 net; and the Socorro Mining & Milling Co., $619,127, and $180,154 net. Both are silver producers.

CRIPPLE CREEK, COLORADO

GOLD OUTPUT.—FLOTATION.—DRAINAGE.—ELLA W. AND ISABELLA.

Gold production of the Cripple Creek District mines for February, as reported by the mills and smelters, is as follows:

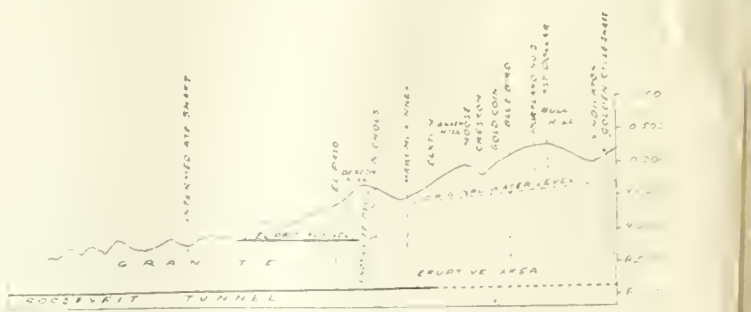
	Tons.	Average.	Total value.
Golden Cycle, Colorado City	29,500	$19.00	$560,500
Portland, Colorado Springs	12,500	21.00	262,500
Portland, Victor mill	17,600	2.31	41,184
Portland, Independence mill	12,250	2.25	27,562
Smelters, Denver and Pueblo	4,100	55.00	225,500
Isabella mines	1,680	2.60	4,368
	77,630	$14.45	$1,121,614

Oil flotation is in operation at the Independence mill of the Portland company, and is reported to be a success. So far no official figures have been published.

Experiments in flotation were undertaken at the Colburn mill of the Ajax company last month, but results are kept quiet.

The Caley mill, on the property of the Jerry Johnson company, resumed ore treatment during the last few days of February. It is expected to run full time during March.

An advance of 244 ft. was made in the Roosevelt drainage-tunnel in February. The breast is now approximately 200 ft.



SECTION OF CRIPPLE CREEK DISTRICT.

east of the Elkton shaft. The adit will continue east for some 500 ft. farther, within the boundaries of the Elkton property. Interesting developments are expected. Included in the advance mentioned was a cross-cut from the tunnel to a point directly under the Elkton shaft. At this place a station was cut preparatory for the connection of the shaft with the tunnel. The flow from the portal remains at 17,000 gal. per minute.

Since the discovery last July at the Ella W. property on Tenderfoot hill, there has been shipped up to February 16, 1916, 638 tons of ore. The average net value, after freight and treatment charges were deducted, was $11.13 per ton. The ore was shipped without sorting. The lowest gross value on

any car of ore was $8.80 per ton; the highest was on the last car, $37.80 per ton. It is reported that Johnson and Mack, who found the ore there, have disposed of their interest to Denver men.

In February the El Paso mine produced 200 tons of ore with a gross value of $44,000. The annual meeting of this company will be held in Denver on March 13, when a full board of directors, nine in number, will be elected.

The Isabella mine produced 1300 tons of $20 ore during the last month. A rich development was reported in this mine a few days ago. The share quotation on the Colorado Springs exchange jumped five points. The new shoot is on No. 15 level of the Lee shaft, and 1300 ft. below the surface. Grab samples of the ore as broken from 42 in. width, are said to assay over 6 oz. per ton.

The Granite company's mines on Battle mountain yielded 3270 tons of $22 ore during February; lessees contributed.

KALGOORLIE, WESTERN AUSTRALIA

Labor Dispute Settled.—Principal Gold Producers in 1915.

The strike of wood-cutters, mentioned in the Press of March 4, employed by the three companies that supply the majority of the mines with firewood, was settled on January 19, after nearly three weeks' stoppage. Work was expected to be in full swing on the 24th. The two mines which did not suspend operations were the Ivanhoe, which substituted coal for wood, and the Kalgurli, which gets its firewood from a private contractor. The total number of men out of work was 4700, consisting of 3800 on the mines and 900 in the wood areas. (There were also 700 others on the Trans-continental railway construction out of work, owing to shortage of rails due to a strike of the coal-miners in New South Wales, and the men employed at the Broken Hill Proprietary company's steelworks at Newcastle, in that State). The new agreement, which extends to June 30, 1918, increases the rate of wood-cutting from $1.08 to $1.14 per ton, with several minor concessions. The credit for amicably settling the dispute is due to P. Collier, minister of mines and acting-premier of the State.

The current wages agreement with the Kalgoorlie-Boulder miners will expire on April 15, and will probably be extended for the period of the War without alteration.

The revenue of the principal gold producers of the State for the past two years is as follows:

	1915.	1914.	Dividends in 1915.
Great Boulder	$2,924,500	$2,827,700	$1,312,500
Ivanhoe	1,900,100	1,814,400	525,000
Golden Horse-Shoe	2,207,400	1,945,700	412,500
Oroya Links	611,100	794,500	.....
Great Fingall	326,200	379,700	.....
Lake View & Star	1,105,400	1,296,900	150,000
Perseverance	1,236,300	1,304,300	.....
Kalgurli	1,112,100	1,284,100	435,000
Sons of Gwalia	1,242,300	1,252,500	203,120
Associated Northern	137,900	127,500	.....
Associated	654,700	714,200	.....

TORONTO, ONTARIO

The Nickel Question Again.—War-Tax Modified.

During the present session of Parliament the nickel policy of the Government has been repeatedly attacked on the ground that all nickel refining should be done in Canada to prevent any possibility of Germany obtaining a supply. It was stated that the International Nickel Co. was controlled, or at least under the influence of Krupp. The course of the Government was warmly defended by Solicitor-General Meighen, who effectually disposed of the wild talk by official figures showing that of the 469,441 shares of the International company only 421 shares were held by persons in Germany and Austria. While admitting that it might be desirable at some time to put an export duty on nickel ore, as a means of encouraging Canadian industry, he urged that to do so at present would cut off the supply of nickel from the American manufacturers, who were making war munitions for the Allies. It is evident that the Government has no intention of disturbing the present arrangement by imposing any restrictions on nickel ore exportation.

The strong pressure brought to bear on the Government by mining and industrial interests has resulted in the modification of several objectionable features of the proposed war-tax on profits. Only paid-up capital will be treated as capital stock, and the value of remaining stock will be based on assets and liabilities on January 1, 1915, stock thereafter issued to be reckoned according to its money-value. Other provisions are introduced with the object of having the profits calculated on the actual money invested, instead of on the nominal capital. The most important change as affecting mining companies is that in determining profits allowance will be made for the exhaustion of ore.

The regular four-weekly statement of the Hollinger company for the period ending January 28 showed a considerable falling-off in revenue, owing to the lower grade of the ore treated. The gross profit was $174,966, from the treatment of 30,817 tons of ore, averaging $9.30 per ton. The working cost was $2.94 per ton. The new central shaft has been cemented down to the 425-ft. level, which is a new departure in northern Ontario mining. Two veins have been cut in the cross-cut which is being driven at this level toward the Vipond boundary.

At the Dome ore has been cut below the 625-ft. level in the new central shaft. This is regarded as unsatisfactory, as the location of the shaft was chosen so that it should not be in ore. Some of the original 40 stamps are being removed to make room for ball-mills, which are regarded as more economical for the secondary crushing of ore. Two tube-mills have arrived. During February 32,040 tons was treated for $163,480.

The machinery in the addition to the McIntyre mill has been installed, giving the mill a capacity of 450 tons. The addition will be used for the treatment of ore from the Jupiter, where the breaking of ore has been at 100 and 200 feet.

The new orebody at the Vipond is averaging much better than ordinary run-of-mine. It has been drifted on at the 400-ft. level for 100 ft., maintaining its width and grade. An extension of the same vein has been picked up at the 500-ft. level. The statement of the Vipond for 1915 shows a total revenue of $248,312, and a net profit of $35,136. Ore reserves are placed at 90,000 tons, valued at $587,280.

On March 15 the Right of Way company paid a 0.5% dividend, or $10,000. The mine, 365 ft. deep, is near the La Rose and has an interesting history, having paid large dividends. A car-load of 1000-oz. silver ore was recently shipped. Four drills and 22 men are employed.

Timmins brothers are developing and equipping the Cheney mine in Gould township.

A car-load of bagged ore is ready for shipment from the Belle Ellen in South Lorrain.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

JUNEAU

During February the Alaska Gastineau mill treated 122,000 tons of $1.02 ore. The March average is expected to be much better. The low value last month, 10c. under that of January, was due to inability to deliver any high-grade ore. In the last two weeks from the stope east on No. 5 level, which is looking better than for some months. At least 150,000 tons of $2.50 ore more than expected can be extracted there. To obtain this the stope had to be prepared. There is 90,000 tons of this value broken in the stope.

The general manager, B. L. Thane, reports the following latest news from the mine:

"Latest results in prospecting the ore-zone east of No. 1 shaft are as follows: Level No. 9 first drill-hole 150 ft. west No. 2 shaft 30 ft. schist ore, average value $2. Second hole 250 ft. west of No. 2 shaft, No. 9 level schist ore 35 ft. Average value before reducing the high assays, $30.40. After reducing all high assays to $10, average value $4.88. This is the highest grade ore ever cut. No diamond-drilling is being done yet at No. 8 east. On No. 7 level 950 ft. east of No. 1 shaft the first 18 ft. averaged $3.30; next 36 ft. low value; next 35 ft. average value, before reducing high assays, $10.45; after reducing high assays to $10, average values $5. The last two holes are in ore. Indications are favorable that the high-grade schist orebody continues on down from No. 5 to No. 10 levels in position as previously reported, and that the value continues satisfactory. The management is doing all it can to hurry development east as much as possible, and will open a stope in this new high-grade ore as soon as possible."

D. C. Jackling thus comments on the above:

"This is the best looking information we have had for some time, and while I think the very high values reported should be considered conservatively, it begins to look like there is no doubt about the existence of a very large continuous orebody in this section that will average at least twice or three times as high as our estimated average. Stopes are all opened on the fifth, ninth, and tenth levels; the sixth level and seventh level are into the orebody, and the eighth will soon be there. It would seem reasonable to expect that within the next 90 days we should be able to get considerable of this ore and thus increase both grade of ore and tonnage, and I am now much more hopeful of early improvement of conditions than I have been for the past two months."

ARIZONA

MOHAVE COUNTY

(Special Correspondence.)—The Oatman Champion Mining Co., which recently started work at the old Black Wonder in the Silver Creek district, is contemplating considerable development. The old shaft will be abandoned for the present, and a new one is being sunk about 75 ft. off the main vein, which will cut it at 200 ft. depth. The vein is an unusual one for this district; at places it is 40 ft. wide, and some samples have assayed as high as $40 per ton. The old shaft is worth about $6 per ton any place from surface to depth 70 ft. The buildings will be re-modeled at an early date; modern machinery will be installed soon.

The Arizona Gold Star Mining Co., which also recently commenced near the Times mine, is making rapid progress in sinking. The shaft is down 60 ft., going through the vein on the hanging wall. The machinery is all on the ground, partly installed. The equipment consists of one 25 hp. and 38 hp. White & Middleton gas-engine and 250 ft. Gardner compressor. In a few days sinking will be resumed with jackhamer drills.

Oatman, March 2.

It is stated that miners at Oatman have asked for a raise in wages from $3.50 to $4 per day. At the Golconda zinc mine, at Union Basin, they receive $4.65 per shift, on account of the price of spelter.

A good deal of interest is being taken in development at the United Western mine. A cross-cut on the 505-ft. level has cut stringers of quartz, one assaying $16.68 across 7 in. The cross-cut is in alternate stringers of highly mineralized andesite, with the entire formation showing good pan values. Mining men who are familiar with development in the Big Jim and United Eastern state that the character of the zone now being cut by the United Western is identical with that lying just outside of the main orebodies in these other properties. The inflow of water is also regarded as a favorable sign, as in the developed mines in the district the veins which hold important shoots usually carry some water.

The shaft of the Boundary Cone is now down 700 ft., and the contact zone between the younger and older andesite has been passed. A good deal of ore has been opened at 505 feet.

The Gold Dust company has taken over 40 acres of the old O'Ryan property adjoining the Boundary Cone, and has started extensive development. There are three shafts from 300 to 500 ft. deep, with more than 3000 ft. of lateral workings. Sinking will be started, and the fault-zone studied.

The Oatman Gold Mining & Milling shaft is down 475 ft., having cut stringers of mineralized ore.

The Oatman United company has ordered machinery of 1000-ft. depth capacity. The shaft is to be sunk to 600 ft. at once.

Water has curtailed work at the Black Range, in which some good ore has been opened.

The Big Jim shaft is down 500 ft., and will go another 100 ft. Cross-cutting at 500 ft. is soon to be started. Work at 100 ft. has cut more ore.

Grading for a 200-ton mill is well under way at the United Eastern. The new shaft is down 60 feet.

The Oatman Amalgamated company's property has been examined by Etienne A. Ritter. Extensive development is to commence.

The Gilt Edge shaft is down 135 ft., and that of the Gold Range 125 ft., both in favorable country.

The Mohave-Oatman Water Co. is an Arizona corporation, capitalized at $1,000,000, to construct a water and sewerage system in the Oatman district, to cost between $250,000 and $300,000. Water will be pumped from wells on the east bank of the Colorado river, through a 10-in. pipe, to an intermediate reservoir of 2,500,000-gal. capacity, a distance of 9½ miles, to a height of 1762 ft. From this point an 8-in. pipe will be run through various townsites to its main reservoir at Oatman, also of 2,500,000-gal. capacity, a distance of 3 miles, to a height of 625 ft. A 4-in. lateral will be constructed from the intermediate reservoir, to Black Range townsite, a distance of 4 miles, and another to the Times townsite, a distance of 3 miles, which supply will be by gravity. The pumping plant will deliver 800 gal. per minute, raised to the intermediate

reservoir, from which point water will be re-pumped to Oatman, the total lift for the two pumping stations being 2400 ft., and a distance of 12½ miles. The sewer will be a 14-in. main, beginning at Oatman, and extending south, running parallel with the water-main, by its intermediate reservoir, a distance of 5 miles. The following towns through which the main line will be laid are Oatman, Oatman City, Mazona, Carter, Ryan Addition, Old Trails, and South Oatman. These towns adjoin each other and are on the Old Trails national highway. Officers of the company are Daniel Cahill, president and superintendent; E. Pritchard Smith, vice-president and general manager; and D. L. Mayhew, secretary and treasurer. The company will be ready to let contracts within 90 days.

Pinal County

(Special Correspondence.)—There seems to be no doubt that another copper-producing mine will be opened on the extensive copper belt extending from Christmas to Ray. The Pinal Development Co., which is energetically developing the Renfro property, four miles east of the Ray Consolidated, reports that a discovery of rich ore has been made on heretofore unexplored ground. This has strengthened confidence in the property, and the remaining shares of the first issue are being subscribed for.

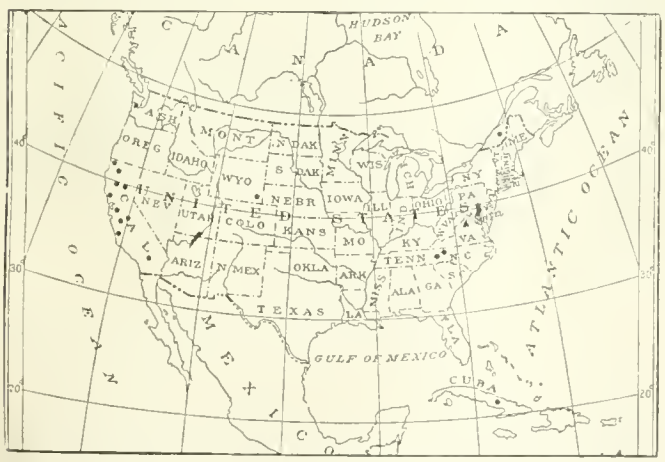
Ray, March 8.

Yavapai County

With each 3c. advance in the price of copper the United Verde company will raise wages 25c. per shift. A minimum of $3.75 is paid with 17c. metal, $4 with 17 to 20c., $4.25 with 20 to 23c., $4.50 with 23 to 26c., $4.75 with 26 to 29c., and $5 with 29 to 32c. The output is to be increased 30% by August, and 30% more in October.

CALIFORNIA

The search for chromic-iron ore deposits in this State continues, as foreign supplies are interrupted and irregular. California is the principal producing State; Shasta county contributing the most ore. Production is increasing, and new deposits are frequently reported. The accompanying map shows the situation of the best-known deposits in North America. Several properties in San Luis Obispo county have been shipping 42% ore for the past six months.



MAP OF NORTH AMERICA, SHOWING CHROMIC-IRON ORE DEPOSITS.

Amador County

The discovery of a deposit of good-grade chrome ore is reported by V. N. Swanson from near Ione. A carload is to be sent to San Francisco.

Nevada County

(Special Correspondence.)—People claiming to represent the Tonopah Belmont company of Nevada are acquiring options on large areas of quartz and placer territory north and east of Grass Valley. Owners state they are offered $400 per acre, subject to development under option. Several ranches in the vicinity of Alta hill containing mineral deposits are included.

Arrangements have been made for re-opening of the South Idaho mine, south of the Idaho-Maryland group. A centrally-located shaft will be sunk, new equipment installed, and efforts made to pick up extensions of important veins opened in neighboring properties. The mine is held under option by Errol McBoyle and associates of San Francisco. A. M. Randal is superintendent.

The Whiskey vein has been intersected at a depth of 850 ft. in the Golden Center mine, and is similar to the upper workings. The company has taken under option two mines near Placerville, Eldorado county.

The Massachusetts quartz claim at Gold Flat, between the Phoenix and Pittsburg mines, has been taken under bond by H. O. Secrist of Nevada City. Preparations are being made for early work. The ore-shoot contains free-milling quartz assaying $40 to $150 per ton.

The Providence shaft of the Champion group, at Nevada City, has passed the 2000-ft. point, and is still advancing. It has three compartments, and the station at the drain-tunnel is timbered with steel. The shaft will soon become the main working thoroughfare of the property, displacing the old Champion shaft. A. Gill is in charge of the work.

Grass Valley, March 6.

After being closed for 20 years, the Washington mine at Ormonde has been bonded by the Von Schroeder Investment Co. The mine is opened by adits, and has a 20-stamp mill. Work will commence early in May.

The Pennsylvania Consolidated Mining Co. is to be dissolved at an early date. On May 1 the Empire Mines Co. will pay the Pennsylvania the last installment of its purchase of $500,000, about $5.75 per share on 51,000 shares.

Shasta County

(Special Correspondence.)—Late developments in the Midas mine, at Harrison Gulch, have been of such a satisfactory nature that the president, J. H. Sharpe, has arranged to take personal charge of affairs. The vein recently cut on the second level was found in the foot-wall of the middle vein, and promises to yield well. It has been opened for over 100 ft., and some of the ore assays $100 per ton. Preparations are being made to develop it at the point of discovery, and to seek its continuation at a lower depth. The working force has been increased, and more comprehensive developments are proceeding in both the Midas and Gold Hill mines. Important additions to the mill are contemplated. The property is owned by the Victor Power & Development Co., with headquarters at Red Bluff.

The vein cut last summer on the 1300-ft. level of the Gladstone, at French Gulch, has been intersected on the 600-ft. level. The 20-stamp mill is running steadily, and over 60 men are on the pay-roll. Preparations are under way to open the vein on other levels, and it is reported sinking of the shaft will be resumed soon. E. Young is superintendent.

Dredging operations in the vicinity of Redding continue to claim interest. The dredge of the Gardella Dredging Co., on Clear creek, four miles below town, will soon start. It will first work the Gibson ranch. Exploration of ground east of Redding is being carried on with a Keystone drill by the El Oro Dredging Co. The U. S. Dredging Co. is preparing to work ground along the bed of the Sacramento river with a suction-dredge. It is reported the Igo Development Co. is planning an early resumption of prospecting along the placer deposits in the vicinity of Igo.

Redding, March 5.

Seven cinnabar claims have been located by C. O. Strayer of Chico on Clover creek, near Millville.

A vein of considerable length has been uncovered at Oak Run by J. T. Beale and W. Winters; it assays $8 per ton.

SIERRA COUNTY

In the laterals of the State highway to be constructed, some of them will be of great benefit to mining centres of this county.

SOLANO COUNTY

Work has been started at the Hastings' estate near Benicia to develop the cinnabar deposits.

TUOLUMNE COUNTY

(Special Correspondence.)—A mill test of ore extracted in developing the Star King mine is being made. The property which is situated east of Tuolumne, has for some time been in the hands of R. C. Kennedy, under whose direction considerable development has been done. A station is being cut at the 925-ft. level, where driving is also in progress.

The Pittsburg-Silver Peak company, which is rehabilitating the Rawhide, has taken an option on the Patterson, an old property situated near Tuttletown.

While sinking a well on land adjoining Sonora creek, near Jamestown, H. S. Shepherd, a mill-man employed at the Harvard, uncovered a promising deposit of gravel. It is capped by several feet of soil. It is thought that a creek once flowed through the property.

An 18-in. vein, which gives high assays, is being opened on the Pease ranch, in the Blanket Creek district, by Wesley and Haley Fitzgerald. It is said to be the intention to install a mill on the property before long.

The Street mine, at Tuttletown, has been unwatered to permit of inspection.

The Cherokee Gravel Co., whose property is situated between Tuolumne and Soulsbyville, has decided to extend the adit several hundred feet farther into the mountain, beneath which an ancient channel is hidden. The adit was started many years ago, and exposes gravel from which rich pannings have been obtained. Those interested are J. H. West and James Harry, of Soulsbyville, and A. Scanavino, of Tuolumne.

Sonora, March 4.

Activity in drilling new oil-wells continues throughout the California fields as shown by the reports made to the State Mining Bureau during the week ended March 4. There were 16 new wells, which equals the highest weekly number yet reported. A remarkable fact is the widespread distribution of the wells among various fields and owners. The large companies own only four of the wells. This probably indicates that the pressure for more oil has now reached to the smaller producers who respond less quickly to market changes than the larger ones do. It is also a notable fact that 14 wells are reported for deepening or re-drilling which is a secondary method of increasing production. The number of tests of water shut-off and abandonment are normal. Oil operators during 1916 will probably spend about $4,000,000 in drilling new wells. The Bureau is now receiving sworn production statements from all producers for the year 1915. These figures are to be used as the basis in levying the assessment to pay for the oil-protection work carried on by the Bureau, and will doubtless give the most accurate figure that has ever been obtained. The assessment to be collected this year is to cover the expense of two years, and amounts to $75,000. There will also be funds established in each county to provide for actual repair work at wells where owners refuse or are unable to carry it out.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—Every mill in the Idaho Springs district is being operated on three 8-hour shifts, and nearly 500 tons is being treated daily. The Argo cyanide plant is treating 150 tons daily from the Gunnell mine; the Newton, 90 to 100 tons from the Gun; the Hudson 80 tons from the Big Five; the Combination 50 tons from the Comstock; the Mixsell 25 tons from the Bride, and the New Era 50 tons from the New Era. The Egan mill up Chicago creek will be brought into commission in a few days, while the Donaldson is also to be remodeled. The Jackson concentrating plant, of 50 tons daily capacity, has been leased to Ellgren, Gustafson & Co. for two years. Two new Huntington mills and five sets of jigs are being installed. The machinery will be started on March 15.

A rich discovery has been made on the fifth level of the Black Eagle mine up Chicago creek. The vein is from 8 to 14 in. wide, and smelter returns average $55 per ton in gold, silver and lead. H. Short is lessee.—— Work will be resumed in a few days on the Quito mine, situated up Chicago creek. This property was a heavy producer previous to three years when litigation arose. J. B. Shepherd of Denver is manager. ——Work has been resumed on the Beaver mine situated up Chicago creek and shipments of $20 smelting ore are in order. J. J. Hoban is manager.

A 5-ft. body of $40 ore has been uncovered on the Edgar vein on Bellevue mountain. Operations are being pushed through the Big Five adit, 800 ft. from the portal. An average of 50 tons of ore is being broken daily. A. L. Carnahan is manager of the Boston Leasing Co., controlling ground below the adit level.

Idaho Springs, February 28.

LAKE COUNTY (LEADVILLE)

Ore shipments from Leadville during February totaled 53,781 tons; 38,000 tons to outside plants and 15,781 tons to the Arkansas Valley smelter. Included was 13,211 tons of zinc ore, mostly from the Western Mining Co., Empire Zinc Co., Colonel Sellers, and Iron-Silver mine. The local smelter is again at capacity after the strike.

Good progress is being made in preparing the Harvard shaft on Fryer hill for unwatering. A station is complete at water-level, and two pumps installed. A power transmission-line is under construction to the property. Pumping was expected to commence about the middle of March.

At the Penrose shaft of the Down Town area the stopes and openings at 800 ft. are being drained. All machinery is working well.

In the Lackawanna district the Mt. Champion mill is treating 75 tons of gold ore daily, worth from $8 to $100 per ton. Ten tons of concentrate is shipped each day. If development continues to be good a 500-ton plant will be erected. Lucien Smith is manager.

Two men were killed in the Anderson adit by the premature explosion of 60 to 70 lb. of dynamite.

SAN JUAN COUNTY

According to *The Silverton Miner*, from present indications the county is to have an early spring. Prospecting will be keenly done, new properties will commence, and old producers are to increase their forces. The tungsten areas will be thoroughly explored. Some of the mines to resume are the Dora and Frisco. The Red Mountain district is busy now, high-grade copper ore coming from the National Bell.

TELLER COUNTY (CRIPPLE CREEK)

The Roosevelt drainage-tunnel was advanced 241 ft. during February. A good deal of other work was also done. The present face is 160 ft. east of the Elkton shaft.

The Golden Cycle shaft is down 2210 ft., and the Ready Money vein has been cut at 2025 ft., where it is as large as 200 ft. above, and of fair value. The Vindicator shaft is 1787 ft., equal to 1650 ft. in the Golden Cycle. During February the Vindicator property produced 5500 tons on company account and 4676 by lessees.

IDAHO

The report of the State inspector of mines, Robert N. Bell, for 1915, covers 134 pages, considerably larger than that for

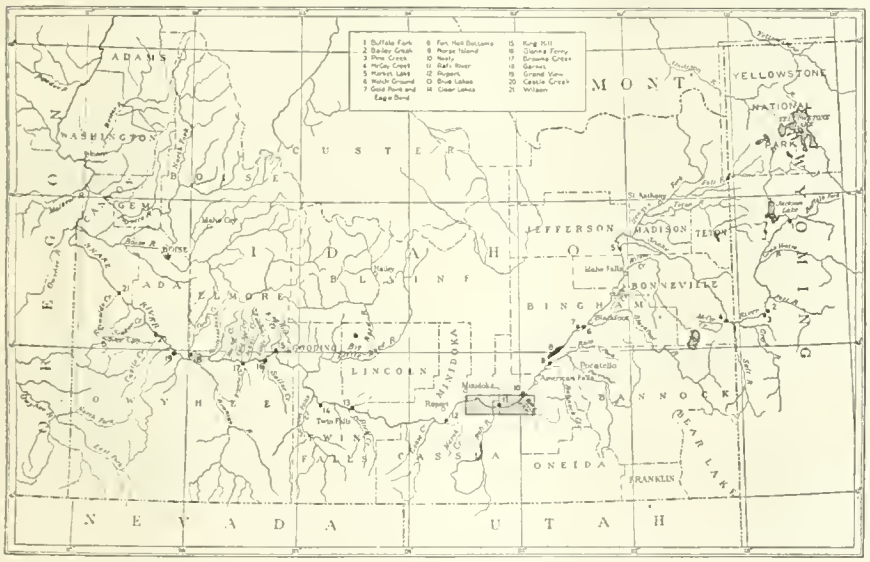
the previous year. It is well illustrated with photographs of mines and mills. The metal production was as follows:

Metal.	Quantity.	Value.
Antimony, pounds	70,950	$ 28,380
Copper, pounds	7,365,000	1,286,665
Gold, ounces	60,746	1,255,619
Lead, pounds	369,242,000	17,243,601
Silver, ounces	12,933,619	6,426,715
Tungsten, pounds	54,000	81,000
Zinc, pounds	93,410,000	12,993,331
Total value in 1915		$39,315,311
Total value in 1914		$24,976,706
Grand total for 55 years		$704,314,681

Antimony and tungsten have not been recorded for many years.

The past year was the most prosperous in the history of Idaho mining. Progress in development was decidedly marked, and expansion is certain throughout, especially in the Coeur d'Alene region, regarding the geology of which Mr. Bell gives a long chapter. The various counties are briefly reviewed, the Snake River fine gold, phosphate and potash deposits, antimony, asbestos, coal, and tungsten. There were up to 7500 men employed, with an average of 6500, an increase of 1300. There were 23 fatal accidents in all operations, equal to 3.54 per 1000 employed, against 5.19 in 1914.

In Bulletin 620-L of the U. S. Geological Survey, J. M. Hill



SKETCH MAP OF SOUTHERN IDAHO, SHOWING MAIN TRIBUTARIES OF SNAKE RIVER AND PRINCIPAL LOCALITIES AT WHICH PLACER WORK HAS BEEN DONE.

discusses the fine gold of the Snake river, which rises in Shoshone, Lewis, and Heart lakes, in the south-eastern part of the Yellowstone National Park. The area of the river basin above the mouth of Rattlesnake creek is 37,000 sq. miles. The placer gold deposits along the river may be classed as stream and bench; the former are often temporary, the latter are older and at higher levels. The gold is in minute particles, most of which are flat, and from 1000 to 2000 colors are required to be worth one cent. It is 945 fine. Since 1902, $149,315 has been recovered from the river above the mouth of the Boise river; but the yield is probably more. A large number of gold-saving devices were used to save the fine gold. Even cyaniding has been tried.

MICHIGAN

The Copper Country

(Special Correspondence.)—Recent prices paid for land in the vicinity of the Mohawk and the Ahmeek properties are the highest ever paid. This should not lead to a misconception that other lands, carrying minerals, can be sold at similar figures. The prices paid were unusually high, but the value was certainly assured. A minimum price of $500 an acre for land that may possibly carry mineral, or may adjoin some valuable working property, or some likely looking prospect, cannot always be counted on.

Houghton, March 7.

MISSOURI

Jasper County

Within the next two months $500,000 will be spent in the Missouri-Kansas-Oklahoma region in the erection of new concentrating plants. They range from 500 to 150 tons per shift.

Discussing present conditions in the zinc-lead region the *Joplin News Herald* states that machinery companies never before knew the like of the demand for all kinds of mill equipment. Scores of costly new concentrating plants have been ordered for all parts of the district. Orders for new mills are coming in to the larger companies at the rate of one or two a day. On one occasion last week the Webb City-Carterville Foundry Co. closed contracts for five new mills in the course of one day. It would be difficult to estimate the population of Joplin as a result of the influx of people brought here by the high price of ore. It is certain that the normal population of 36,000 has been swelled to something like 50,000, and vacant houses are at a premium. Rental properties are hard to find and rents are 100% higher than they were three years ago. Hotel facilities are not adequate to meet the requirements of the strangers in the city, and for this reason extensive improvements in hotel accommodations and in apartment-house facilities are contemplated.

Owing to the increased price of chemicals, assayers at Joplin, Webb City, and Galena have standardized and raised charges. The following prices are asked for assays: zinc, 75c.; zinc and moisture, $1; zinc, iron, and moisture, $1; lead, $1; sulphur, $1; lime, 75c.; silicate and blende, $1.50; moisture, 25c.; zinc and iron, $1; lead and moisture, $1.25; and zinc in tailing, drill cuttings, etc., $1.

Oklahoma oil-men have purchased the McDonald mine at Prosperity for $175,000. Ore is mined at 180 ft. A good 350-ton mill is part of the equipment.

The Tom C. mine of the Prosperity district, bought last September by T. F. Coyne for $15,000, has been sold by him to R. R. Conklin of New York for $150,000. A 200-ton mill, which yields 63% blende is included. Fifty men are employed.

A 250-ton mill is to be erected by the Evans-Hall-Soy company in the Duenweg district.——In the seventh drill-hole of Molloy, Cameron & White, at Duenweg, 9.06% blende was cut from 130 to 180 ft. depth.——The Wilson mine at Duenweg has been sold to the Onamena Mining Co. for $100,000.

NEVADA

Humboldt County

During February the Nevada Packard mill produced $15,587, work being affected by bad weather. The March yield is expected to be $20,000. The plant treats 100 tons a day. At the end of March extraction of ore will commence from the fine shoots opened in adits B, C, and D.

A compressor and machine-drills will probably be installed at the Packard North Extension mine, where development is encouraging.

Lyon County

Officials of the Nevada Douglas company consider that the leaching plant will produce copper at 6c per lb. from 3% ore. Fine-grinding machines have been ordered to pass the ore through 60 mesh, doubling the Wedge furnace capacity. About 25 tons of metal has been precipitated, and the first shipment made. The annual report shows that revenue during 10 months ended December 31 was $191,107, four assessments realizing $375,910, bank loans, $80,500, and sales of ore, $36,071. Mill construction cost $147,152, and development, $38,068. By the purchase of the Western Nevada mine, reserves are increased by 250,000 tons of 3.5% ore.

Mineral County

(Special Correspondence.)—Jesse Knight of Utah, Adams and O'Neil of Los Angeles, and J. H. Miller of Hawthorne, last December bought the Golden Pen mine, which up to that time had been a shipper of ore, worth from $116 to over $1000 per ton, with smaller shipments going as high as $18 per pound. All the new owners visited the Golden Pen mine in the last week in February. Work has been done steadily since its purchase, and it is reported that plans have been made for extensive development, which includes a plant to treat the bodies of mill ore already opened. All ore of shipping grade has been broken during development, and a shipment of 60 tons of $100 ore is now being hauled to the railroad.

A 40-ton shipment, from the Miller-Meaker lease on the Queen Regent Merger Mines Co., has been sent to the Hazen sampler. The company reports that the west drift on the second level in the main shaft, out 120 ft. is in good ore of improving value.

The Last Hope mine was recently sampled by engineers for George Wingfield, and it is said that it will be taken over by him, and extensive development undertaken. The mine has already shipped $30,000 worth of high-grade ore from shallow workings.

On the Ed. Lappatt group of 17 claims, three leases were let during February, and already from the Stockton and Gardner lease, a carload shipment has been made. One of the other lessees states his first carload will be sent out inside of 30 days.

S. W. Van Syckel of Newark, New Jersey, has taken an option on a group of claims.

Rand, February 28.

At the Luning Idaho mine, north of New York canyon in the Luning district, a large tonnage of 6% copper ore has been developed. Road construction is to be started when the ground is dry. John S. Skuse is in charge.——Near-by is the Nevada Champion mine, the management of which has made a contract with the Western Ore Purchasing Co. for 30,000 tons.

Nye County

Tonopah mines produced 8311 tons worth $174,858 last week. At 1540 ft. in the Extension the vein is 32 ft. wide.

UTAH

Boxelder County

Wages have been increased 25c. per shift at the Lakeview zinc mine on Promontory point, Great Salt Lake; 130 men will benefit.

Salt Lake County

During 1915 the Bingham Mines Co. shipped 44,975 tons of ore, containing 2,244,078 oz. lead, 1,221,219 lb. copper, 188,216 oz. silver, and 3399 oz. gold. The profit was $95,465. This company controls the Eagle & Blue Bell of Tintic.

During 1915 the Utah Metal & Tunnel Co. in seven months, and its Bingham-New Haven mine in twelve months, produced a total of 16,914 oz. gold, 475,894 oz. silver, 9,860,089 lb. lead, and 2,873,815 lb. copper. Net profits were $329,628. In January 1916 the Bingham-New Haven yielded 704,155 lb. lead and 348,096 lb. copper. The profit was $103,824, while that of the Utah Metal was $45,000, making $148,824 for the month.

At Garfield a 100-ton sulphuric-acid plant is to be erected, to be in operation by August 1, by the Garfield Chemical & Manufacturing Co. The A. S. & R. Co is said to be interested in the project. E. L. Newhouse, Jr., is manager.

Summit County

Seventy men are at work for the Federal Leasing Co. in the upper workings of the Ontario mine at Park City.

Tooele County

The International smelter at Tooele was recently visited by officials of the A. S. & R. Co. Two units of the Cottrell fume plant are in operation, while material for the lot is arriving. The whole will cost $160,000.

WASHINGTON

Ferry County

(Special Correspondence.)—In the Belcher Mountain mines are extensive deposits of iron-sulphide ore, which contain small gold and silver values, with prospects for copper in the lower levels. The Copper Key is to be drilled by Boyle brothers for the Granby Consolidated company, which is said to be negotiating for the property.

During January and February the Lone Pine mine produced 34 carloads of ore, assaying $12 per ton, mostly from the 450-ft. level. Last week it produced 130 tons.——In the suit of the Lone Pine-Surprise Mining Co. v. the Insurgent Gold Mining and Insurgent Leasing companies, the Superior court has rendered a decision in favor of the defendants. The suit was for the value of ore alleged to have been taken by the leasing company from Lone Pine ground.

In the Enterprise district, near Covada, the adit at the Syndicate mine is in 950 ft. A contract has been let to extend it 50 ft., in expectation of cutting the Rising Sun vein, which has been opened by the Advance Mining Co. on adjoining property, at a depth of 600 ft. The Syndicate company has operated 14 years, spent $25,000 on development, and has sold no shares.

Republic, March 3.

Stevens County

(Special Correspondence.)—The Silver Queen mine, near Kettle Falls, in which development was started over 20 years ago, recently shipped its first carload of ore to the smelter.

The Byron E. Sharp Mining Co., owning 10 claims which produced $300,000 from near the surface in early years, and was abandoned because of the ore containing zinc, proposes to re-open this, the Cleveland group. The property is situated north of Springdale. About 15,000 tons of ore is reported to be on the dump and developed above the adit-level. The ore contains silver, lead, zinc, and antimony. A 50-ton concentrator will be installed.

A Spokane syndicate has taken over all the property of the Orient Gold Mines and will begin extensive development and the erection of a cyanide mill as soon as spring opens.

Springdale, March 3.

During 1915 the United Copper mine, near Chewelah, received $117,269 from smelter settlements on crude ore and concentrate. The products yielded copper, gold, and silver. The company operated at a loss, the gross indebtedness being $111,553. The mine is in good condition.

No. 1 lead furnace was blown-in at the Northport smelter last week; No. 2 will soon follow. There is plenty of material to smelt.

At the Electric Point mine a good deal of ore has been developed, and ready for shipment is 1000 tons of carbonate and over 500 tons of very rich lead ore.

WYOMING

Lincoln County

In Bulletin 620-O of the U. S. Geological Survey, G. R. Mansfield describes the work of a reconnaissance for phos-

phate in the Salt River range. Certain land in the area was withdrawn, and the presence or absence of phosphate beds west of the crest of the range was the subject of investigation. Indications point to the fact that the deposits are probably inferior to those in south-eastern Idaho, both in thickness and quality. A considerable body of medium-grade rock occurs, which may be considered as a valuable reserve deposit. It is not likely that the mineral in this area will be of any notable importance in the near future.

CANADA

British Columbia

A sulphuric-acid plant is to be erected at the Trail smelter to supply the zinc and lead refineries. The copper refinery will need the acid later on.

Ontario

Electric power is to be available for Kirkland Lake companies, as the Northern Ontario Light & Power Co. is to supply the current. This is of importance to the district.

HONDURAS

René Kilhauer is developing silver-zinc mines at Valle de Angeles. The San Antonio mines, near Tegucigalpa, formerly owned by Callejas, have been sold to a New Orleans syndicate. The mill at the Socorro mines has been closed down, and is being re-erected on the Santa Helena property, near Santa Lucia. Attempts are also being made to sell the Danli gold mines, but the scattered character of the rich pockets has made it difficult to operate on a systematic scale.

MEXICO

Smelting operations in Northern Mexico, notably Monterrey, Matehuala, and Chihuahua, are again interrupted by the political complications. The American Smelting & Refining Co. has called all its employees out of Mexico. This is particularly regrettable, as a new start had been made at several of the plants.

Hidalgo

During January, Santa Gertrudis made a profit of $80,000 from 20,503 tons of ore. The report for the last quarter of 1915 shows that 58,532 tons of ore gave a profit of $135,000. Development totaled 4441 ft., 2342 ft. being in payable ore. Sinking was resumed at the 20th level Counter shaft. The mill worked at 60% capacity. There are ample supplies for full time, but labor is lacking, and is likely to continue so until the country is more settled.

Sonora

It is estimated that over 15,000 burros are needed to carry ore between Cumpas and Nacozari.——The Nacozari Consolidated mines, near Pilares de Nacozari, is shipping ore regularly to El Paso. The mine is in good condition. A roasting-plant is to be erected to desulphurize the zinc ore.——A number of mines near Nacozari are to be re-opened, including the Promontorio of Phelps, Dodge & Co., 25 miles south of Moctezuma.

Shipments of minerals from Sonora through Agua Prieta during February totaled 9391 tons, valued at ₱2,015,700. Nacozari sent 9126 tons of copper and El Tigre 6204 lb. silver bullion. The estimated value of copper, gold, and silver was ₱1,429,000, ₱198,000, and ₱388,700, respectively.

Considerable activity is reported from Cananea. The Cananea Consolidated has eight blast and two reverberatory furnaces in operation. The Puertecitos mine is supplying rich ore. The first 1000-ton flotation unit is working, the second soon will be.——The Democrata company has 400 men and two furnaces treating 500 tons of ore daily.——Lead-zinc-silver concentrate is being produced by the Duquesne company from the Catalina mine.——Lack of transport facilities is hampering the Santa Cruz district, a little south of Cananea.

PERSONAL

C. R. Corning is in Cuba.

Robert B. Rogers is at the Plaza hotel.

Albert L. Waters is at Globe, Arizona, for a few weeks.

P. Kirkegaard is opening some gold mines at Cordova, Ontario.

W. E. Thorne is expected in London from the Lena district, Siberia.

G. G. S. Lindsey is expected in London on his return from China.

C. R. Pinder is consulting engineer to the Mexico Mines of El Oro.

C. H. Benedict, metallurgist to the Calumet & Hecla is in Florida, on a holiday.

Roger W. Strauss, of the Guggenheim organization, was in San Francisco this week.

E. A. Cappelen Smith has been elected a director of the Chile Copper Company.

George J. Adams has been appointed Professor of Mining Geology at the Peking university.

William Ralph has been appointed superintendent of the Tarbox mine near Saltese, Montana.

Mark Harris, superintendent of the Adirondack mine at Sheridan, Washington, is at Portland.

Frank A. Ross, of Spokane, has been appointed the Washington representative on the Naval Consulting Board.

Leon J. Pepperberg, consulting geologist and engineer, announces the removal of his office to 718 New Call building, San Francisco.

Lafayette Hanchett has been selected by the Utah section of the A. I. M. E. as State representative on the Naval Consulting Board.

S. A. Wookey, of the Hollinger, is manager of the Schumacher mine, in place of J. Houston, now assistant-manager of the Dome, at Porcupine, Ontario.

Morton Webber, who has held a commission with the Royal Field Artillery in France, Gallipoli, and Serbia successively, has been invalided home, and is now at the Ritz hotel, London.

Frederick G. Clapp and Myron L. Fuller, the managing geologists of the Associated Geological Engineers, announce the opening of a New York office at 3112 Equitable building, 120 Broadway, in charge of Mr. Clapp, managing geologist of the petroleum division.

Schools and Societies

The Department of Geology of Princeton University has published its announcement for 1916-1917. Details are given of the courses offered and examinations.

The last Bulletin of the Massachusetts Institute of Technology contains the report of the president, Richard C. Maclaurin, also the reports of administrative officers. There are 1900 students registered, a record. The staff totals 308 instructors. Gifts received during 1915 amounted to $877,815. The operating revenue from all sources was $721,704, and expenses $678,782.

The U. S. Civil Service Commission announces an open competitive examination for assistant technologist in oil and gas production. From the register of eligibles resulting from this examination, certification will be made to fill a vacancy in this position in the Bureau of Mines, for service in the field, at a salary ranging from $1800 to $2100 per annum. Applications must be filed at Washington, D. C., by April 4, 1916.

THE METAL MARKET

METAL PRICES

San Francisco, March 14

Antimony, cents per pound	44
Electrolytic copper, cents per pound	27.75
Pig lead, cents per pound	6.95—7.90
Platinum, soft metal, per ounce	$88
Platinum, hard metal, 10% iridium, per ounce	$92
Quicksilver, per flask of 75 lb	$235
Spelter, cents per pound	22
Tin, cents per pound	16
Zinc-dust, cents per pound	30

ORE PRICES

San Francisco, March 14

Antimony, 50% product, per unit, of 1%, or 20 lb	$2.25
Chrome, 40% and over, f.o.b. cars California, per ton	11.00
Magnesite, crude, per ton, f.o.b.	8.00
Magnesite, plastic, no iron and lime, calcined, ton	30.00
Magnesite, refractory, 11% iron, dead-burned, ton	35.00
Manganese, 50% metal, 8% silica, per ton	12.00
Tungsten, minimum 60% WO_3, per unit of 20 lb	60.00—65.00

In the March Bulletin of the Canadian Mining Institute the concentration of molybdenite ores is discussed by Henry E. Wood of Denver, Colorado. While it is desirable to make a high-grade product, it is not essential, and 70 to 75% concentrate will bring proportionately as much per pound of molybdenite content as one of 80 or 90%. The demand for molybdenum is likely to be maintained and increased. Molybdenum is four times the price of two years ago, compared with ten times in the price of tungsten.

New York, March 9.

Antimony, 50% product, per unit	$2.70
Tungsten, per unit	80.00

These prices are for small quantities. In molybdenum no business is being done.

EASTERN METAL MARKET

(By wire from New York.)

March 14.—Copper is firm, but there are no buyers, spot lead is scarce, there are plenty of buyers but no sellers; spelter is dull and uncertain, with London very weak.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending.	
Mch. 8	56.75	Feb. 2	57.02
" 9	56.75	" 9	56.79
" 10	56.75	" 16	56.62
" 11	56.75	" 23	56.86

The silver market is fairly steady, depending mostly on European support. India is quiet, although China bought a little. Exports from London to India to February 16 were 6,100,000 oz. less than in that period of 1915. American supplies in London have been small. France is to coin silver for Serbia and Montenegro.

During February the Inspiration produced 8,300,000 lb. copper. Greene-Cananea yielded 5,180,000 lb., 838,000 lb. of which was custom metal.

Ahmeek will pay $3, Allouez $1.50, and Osceola $1 per share.

The copper situation in Canada from the consumer's point of view is discussed in the March Bulletin of the Canadian Mining Journal by G. C. Brown. The output in 1915 was 102,000,000 lb., an increase of 26,000,000 pounds.

Tin is firm at 55 cents.

In Sweden antimony is $2.37 per lb., aluminum $1.25 per lb., and tin $1.40 per lb. This is the result of the War.

Eastern Metal Market

New York, March 9.

The copper market is dull, and quotations are much easier, a condition which is attributed, more than to any other cause, to difficulties in making deliveries in New England. Great Britain has modified her regulations, which were announced on March 1, designed to stop speculation in materials needed for the manufacture of munitions. The order, which prohibited dealings in futures, has not so far lessened the cost of electrolytic copper, which stands at £136. The regulations, or some other influence, has brought down the London quotation for zinc sharply. The domestic market for zinc is dull and much lower. Lead is soaring, independent producers having obtained 7c. per lb., although the A. S. & R. Co. quotes 6.60c. The demand is heavy, and a scarcity of spot lead seems imminent. The independents will soon be sold-up, some of them are already, and then the A. S. & R. Co. will have the field to itself. Meanwhile the big interest is thought to be loading up with ore and raw materials on the basis of its quotations. It is selling at 6.60c., but to a restricted degree. Tin is tightly held to cover old contracts; Great Britain is being stricter than ever in the matter of issuing licenses to ship. Antimony and aluminum continue firm, and little is to be had of either for spot shipment.

Blast-furnaces and steel-mills are making new production records. The railroad-freight embargoes and car shortages are more severe than ever, and holding up shipments of both raw materials and finished products. Shipments to New England points and to the Atlantic seaboard are particularly difficult to get through. Shippers are now fearing a general railroad strike, on which the men have been taking a vote.

COPPER

The market has become very quiet, and quotations have continued to grow easier, until near-by deliveries of electrolytic are to be had at from 26.50 to 27c., cash, New York. The action of Great Britain, referred to a week ago, prohibiting dealings in future positions of the metals has had but little effect on the New York market, and not so much on London as was expected, as electrolytic in the latter city is still quoted at £136. Standard copper at London, however, has declined heavily. The new regulation in its original and severest form was only in existence four days, March 1 to 4, and on those days no prices were cabled to the New York Metal Exchange, as the metal exchanges at London and Glasgow were practically closed. The British Ministry of Munitions yielded on March 4 to the importunities of the British metal-dealers. As a result the order was modified to the extent of not applying to purchases made outside of the United Kingdom. The modification read: "The new regulations will not be enforced in the case of purchases made outside the United Kingdom until the metal reaches this country. Export orders and sales to allied or neutral countries through authorized channels will be treated as consumers' orders."

More effective than the British order, in making trade quiet, has been the bad railroad situation existing in the East, and which is steadily growing worse. Brass-mills in New England are hungry for copper, which cannot be delivered to them because of the embargoes on the New York, New Haven & Hartford railroad and other lines. How irregular deliveries are is indicated by the case of a New Jersey rolling-mill. It was clamoring for copper, then in one morning had 16 carloads placed on its railroad siding with instructions to unload within 48 hr. or pay demurrage. At the same time the ground was covered with over a foot of snow. It can again be pointed out that plenty of spot electrolytic copper is now available, in spite of the repeated declarations of a scarcity, heard on all sides a few weeks ago. Lake is nominally quoted at 27c., cash. Exports this month total 4167 tons, up to and including the 8th.

ZINC

Inability to make deliveries in New England, and to a lesser extent in other directions, because of the railroad-freight congestion, has had a serious effect on zinc. For a week prices have been on the down-grade, and the market today is not far from 18.75c., New York, for prime Western. Offerings at concessions are plentiful but consumers are staying out of the market. The London spot market dropped £8 on the 6th, and £4 more on the 8th, and it is thought that prices are being adjusted there to accord with the wishes of the Ministry of Munitions. A continuance of the decline will start buying on the part of the galvanizers, most of whom lose interest when the quotation rises above 17 cents.

The quotation for sheet-zinc is unchanged at 25c., f.o.b. mill, carload lots.

LEAD

A most peculiar situation prevails in this metal. Independent sellers sold their product yesterday at from 6.75 to 7c., while the A. S. & R. Co. was quoting and, to a limited degree, selling at 6.60c. The leading interest advanced its quotation on the 3rd to 6.40c., New York, or $1 per ton, a move which astonished the trade, inasmuch as independents were then selling at 6.75c., and finding many buyers for their offerings. Both the foreign and domestic demand has been good. Buyers have seemed willing to pay almost any price. On March 6, the A. S. & R. Co. announced another advance, this time $4 per ton, bringing its New York price to 6.60c. Sales were made yesterday by independents at 7c. A peculiar phase of the situation is that New York and St. Louis are on a parity. Under the circumstances the only manner in which prices may be gauged is to give both price levels, or to strike an average between those of the big company and those of the smaller producers. The crux of the whole situation is that near-by lead is scarce and becoming more so. The big interest is selling only to its regular customers and then only in such quantities as it, and not the customers, believes should be doled out. The independents are rapidly becoming sold-up, only a few remain in the market, and these can command the high prices alluded to. The London market is gaining strength. Exports from the 1st to the 8th totaled 701 tons.

TIN

Moderate quantities have been taken in the past week, but the general aspect of the market has been dull. Prices, however, are firm and promise to go higher. The quotation yesterday was 49c. for spot. It is steadily becoming more and more difficult to obtain licenses to ship from London and the Straits Settlements, and brokers here are unwilling to sell, inasmuch as they may need the metal to cover old contracts. This condition exists despite the fact that there is a fair quantity here, and a large quantity is afloat. Arrivals this month, up to the 8th, totaled but 145 tons. There was afloat on that day 6558 tons.

ANTIMONY

The market is firmer than ever, with Chinese and Japanese grades quoted at 44 to 45c., duty paid. For needle antimony 24½c. has been bid for good-sized quantities.

ALUMINUM

Quotations for No. 1 virgin aluminum, 98 to 99% pure range from 61 to 64c. New-comers in the market must pay high for this metal; the regular consumers like the automobile companies obtain their metal much lower under contracts.

MINING DECISIONS

New Mining Regulations

The Mining Regulations of the Land Department have been revised and a copy of the new regulations dated August 6, 1915, has just been printed in Vol. 44, Land Decisions (advance sheets), page 285, *et seq.*

Mineral Lands—Do Not Include Fossil Deposits

Fossil remains of dinosaurus and other pre-historic animals having a value for scientific research are not minerals, within the meaning of the United States mining laws, and lands containing such remains are not subject to entry under such laws.

In re Douglass (Land Department), 44 Land Decisions, 325. August 6, 1915.

Mining Leases—Taxation

The minimum royalties required to be paid to the lessor under a mineral lease are assessable and taxable as "credits" for the year in question and are in the same category as rents.

State v. Royal Mineral Association (Minnesota), 156 Northwestern, 128. February 4, 1916.

Negligence of Mine Owner—Discharged Employee

A man who had been employed in a mine as a foreman, had quit, and was returning to get his tools and pay-check when killed by a gas explosion. Held, that he was entitled to protection under the provisions of a miner's safety-act, and his widow was permitted to recover damages for his death resulting from a violation of such provisions.

Romani v. Shoal Creek Coal Co. (Illinois), 111 Northeastern, 88. February 4, 1916.

Oil Lease—Measure of Damages for Breach

The lessee of oil-land, after driving a well to a great depth and at considerable expense, violated an express provision of his contract by withdrawing the well casing. Held, on suit by the lessor for damages, that inasmuch as the land had been proved to be without value for oil, the measure of damages should be the value of the casing when removed, and not the cost of replacing it or driving a new well.

Jonhson v. Hinkle (California), 154 Pacific, 487. January 28, 1916.

Oil Land Not to be Partitioned in Kind

A lessee under a mineral contract may not contest the title of his lessor as an owner of an undivided interest with others, and compel him and his co-owners to make a judicial partition in kind of the property leased. Known oil-lands, like mines, cannot be judicially partitioned in kind, on the suit of one of the co-owners. A lot without oil under the surface falling to one co-owner would work incalculable damage to him to whom it was awarded, due entirely to the consequence of dividing the land.

Gulf Refining Co. v. Hayne (Louisiana), 70 Southern, 509. January 10, 1916.

Aluminum imports during 1915 were 8,534,834 lb. as metal and $301,865 value of manufactured metal, against 16,241,340 lb. and $1,308,036 in 1914. Exports of domestic metal and manufactures amounted to $3,682,117, compared with $1,546,510 in 1914 and $966,094 in 1913.

Antimony imports in 1915 totaled 3,374,012 lb. in ore, and 17,484,030 lb. as metal, compared with 1,986,082 lb. and 13,070,381 lb. respectively in 1914.

COMPANY REPORTS

NATOMAS COMPANY OF CALIFORNIA

The gross earnings of the dredging department of this company in 1915 were $2,416,960. Net earnings totaled $1,675,076, as follows: dredges, $1,324,953; rock-crushing plants, $159,308; and water, land, rentals, crops, etc., $190,816. In 1914 the total was $1,548,070. After paying interest on bonds and notes there was $833,767 over, of which $831,592 was written-off for depreciation.

EAGLE & BLUE BELL MINING CO.

The report of the Eagle & Blue Bell Mining Co. of Tintic, Utah, for 1915 shows the following results: Development covered 3350 ft. This opened a silver-lead orebody, which was first encountered on the 1550-ft. level in 1914. Stoping was in progress on the deposit, proving it continuous for 400 ft. in length, averaging 60 ft. wide and extending from a point 120 ft. above the 1550-ft. level down to a point 100 ft. below the 1700-ft. level. This gives this immense orebody a vertical depth of 370 ft. Ore shipments totaled 26,745 tons, containing 1228 oz. gold, 441,263 oz. silver, 8,275,734 lb. lead, and 3806 lb. copper. Gross revenue was $493,678, and profit $143,345, of which $133,972 was paid in dividends.

OSCEOLA CONSOLIDATED CO.

The past three years of this Michigan company compare as follows:

	1915.	1914.	1913.
Ore treated, tons	1,361,089	1,198,447	735,011
Copper in ore, pounds per ton	14.5	13.5	15.4
Refined copper, pounds	19,731,472	14,970,737	11,325,010
Price received, cents per pound	18.19	13.11	15.48
Cost, cents per pound	10.03	10.79	12.30
Revenue	$3,590,708	.....	.....
Profit	1,610,860	.....	.....
Dividends of $11 per share	1,057,650	.....	.....
Surplus	$2,166,646	$1,613,436	$1,519,300

The Osceola, North and South Kearsarge mines contributed 272,073, 612,831, and 476,185 tons of ore, respectively. On No. 42 level of the first is its best development in recent years.

BRUNSWICK CONSOLIDATED GOLD MINING CO.

If more Californian companies issued such interesting reports as the above for the past year, mining men would know what was being done at the large mines. In the reports of the general manager, R. Chester Turner, and superintendent, C. H. Mallen, are the following notes:

A new steel 85-ft. head-frame and 20-stamp mill were erected at the vertical shaft, resulting in costs being reduced from $8.45 to $6.78 per ton. A further drop is expected. Development down to a depth of 1100 ft. amounted to 2905 ft. The shaft is to be sunk to 1300 ft. Reserves are 16,000 tons blocked and ready for stoping, and a good tonnage of low-grade ore indicated by exposed faces. Sorting is to be tried. The mine is a puzzle to miners on account of faults and intrusions in the orebodies.

The old mill worked the full year; the new one from October 18. The respective stamp-duty was 2.616 and 2.998 tons. A total of 22,004 tons of ore was treated, yielding $223,557, and an operating profit of $72,565. The new head-frame, mill, etc., cost $39,751. Three dividends absorbed $71,152. The year commenced with a balance of $83,034, and ended with $49,629, the new equipment accounting for the decrease. Since 1893 the output is $1,384,844, and dividends since 1906, $203,315. Interesting mill data will be given in another issue of this journal.

EDITORIAL

T. A. RICKARD, Editor

FLAT RIVER is the great lead-mining district of Missouri. We have arranged for regular correspondence concerning local mining and metallurgical developments. The first of these news-letters appears on another page of this issue.

COPPER is favorably affected by the cessation of smelting operations in Northern Mexico and the possibility of hostilities entailing a supply of munitions for an American army in active service. Purchase of supplies of this metal by the United States Government is reported.

FREE IMPORTATION of dredges and parts thereof, for a period of 10 years after the declaration of peace, is recommended by the consultative committee of gold producers in Russia. Meanwhile, the War is said to be facilitating the stealing of gold, owing to the loosening of organization.

OUR New York correspondent makes interesting comment on the metal market. Evidently the demand for lead has proved too strong for those seeking to keep down the price of that metal. Consumption of metals in the making of munitions proceeds at a tremendous rate, as is indicated by the figures quoted by our correspondent on another page of this issue.

CRITICISM of the use of English by technical men is an ungracious task, for a man is as sensitive in regard to his use of language as he is concerning the cut of his clothes; yet we cannot forbear from protesting against the use of 'uprise' by the author of Bulletin 86 of the U. S. Bureau of Mines. In this paper, on the effect of earthquakes at the Panama Canal, the word 'uprise' is used as a geologic term indicating elevatory movement. The question, we are told, is whether "the canal is in danger of an uprise." It may be in equal danger of a 'downsink.'

WE take pleasure in drawing attention to the article on the pipe-line supplying the Nevada Wonder mine with water, as described in this issue by Mr. J. A. Burgess, the resident manager. It is a good example of what a technical description should be, in that it gives useful information in a straightforward way, assisted by good drawings and just that touch of individuality that lends human interest. The special difficulties against which it was intended to guard and the arrangements effected for that purpose are portrayed with sufficient detail to make the article helpful to other engineers and managers of mines. Excessive cold causes trouble to the users of water in Western regions, especially those drawing it from high mountains, as is commonly the case. Mr. Burgess describes how the telephone service, flow-indicator, and other protective devices are supplemented by an organization of the staff so that each member of it is ready to act in an emergency. The apparatus for giving warning of a cessation of flow and the electrical coil for preventing this apparatus from being crippled by cold are highly ingenious. We are not surprised at the good reputation of the Nevada Wonder management.

GOOD SENSE, it seems to us, characterizes the attitude of *The Globe*, at Joplin, in regard to the relation of the mines to the smelters in that important zinc district. Our contemporary in Missouri is in agreement with the opinion we expressed several months ago in regard to the demand for a 'smelter trust' investigation, which proved a mere mare's nest of suspicion. Now it is suggested that the best way of aiding the mining industry of the Joplin district is to work for the establishment of an open zinc market in New York. It is claimed that the mine operators are at the mercy of the metal-selling agencies, which fix the price arbitrarily to suit their own extensive speculations. Undoubtedly the New York metal market is anything but healthy in its tone; the brokers are speculators, and those who fix quotations are dealers themselves. If the Department of Commerce cannot be persuaded to make an investigation, it would be worth while for some representative of the mining industry to do so. Why should not the American Mining Congress or the Mining and Metallurgical Society of America justify its name and its reputation by performing this public service?

TAMARACK, as most of our readers know, is the famous copper mine adjoining the Calumet & Hecla, on the Keweenaw peninsula, Michigan. The deepest shaft for metal mining until quite recently was the Tamarack No. 5, which is 5368 feet in vertical length. During the last two years, however, the St. John del Rey shaft, in the Minas Geraes province of Brazil, has sunk to 5826 feet, this being now the deepest metal-mining opening. The original Tamarack enterprise, as planned by Capt. John Daniell, was a shaft to intercept the Calumet & Hecla conglomerate on its dip, which is 38°. This bold venture proved successful, paying $9,000,000 in dividends between 1888 and 1907; but the conglomerate became so impoverished in depth as to cause abandonment of deeper exploitation. Now the Calumet & Hecla has offered $59 per share for the remainder of the Tamarack stock, represented by an issue of 60,000 shares, which have sold during recent years

for less than half the figure mentioned. The Tamarack shareholders claim that their stock is worth more than $50 to the Calumet & Hecla, which, by reason of its position and equipment, can operate the mine at a profit when the Tamarack company itself could make money only when the metal market was highly favorable. It seems to us that a business transaction should be mutually advantageous, and that in this case the Tamarack can afford to sell the mine for less than it is worth to the Calumet & Hecla, while the latter can afford to pay more than it is worth to the Tamarack, the result of such a compromise being to the gain of both, as compared with the spasmodic operation of the mine on Tamarack account.

After the War—II

In a preceding article, we drew the conclusion that if the War should last no longer than twelve months more, the belligerent countries of Europe would not be subject to financial bankruptcy or industrial collapse. Let us proceed to inquire what will be the effects on the industry and commerce of these United States. In the first place, the supply of labor may suffer from a decrease of immigration on account of the contending pulls of patriotism and taxation in the chief countries now at war, and it may be restricted further by Congressional legislation imposing an educational test on those coming to our shores from Europe. If the latter is vetoed again, that check may not become operative, and there is a probability, no matter how the War ends, that the influx of population will be resumed from the countries bordering upon the Mediterranean and the Adriatic, if not from northern and western Europe. However, the rise in the cost of living and the logical demand for higher wages will hinder a too exuberant expansion of industry in the United States. Moreover, the organization incidental to war will not be discarded in a hurry by the European nations; on the contrary, the democracies that lacked organization before the great struggle are likely to maintain that organization for international industrial competition, while German efficiency will be unabated. France, Russia, and England will have learned a lesson. Great Britain is sure to discard her historic policy of free trade and adopt a protective tariff, in the first instance against her chief enemy but probably against the world at large as well, establishing preferential rates with her overseas dominions, which in turn will seek to exclude the manufactures of the Germanic countries. Even if some measure of reciprocity is arranged with the United States, it is not likely that imports into Great Britain, particularly manufactured products, will be as free as heretofore. We anticipate many checks to international trade on this account. The demand for American raw materials and products partly manufactured will be immense, but commerce in finished manufactures will suffer both by reason of tariffs and of economy in Europe. On the other hand, the United States is being given an opportunity to find new customers elsewhere, as in South America and Asia. In such expansion of trade this country has two advantages, namely, the interval of preparation while her competitors are fighting and the opportunity to accumulate a big reserve of spare capital. At present the first advantage is not being utilized in a large and systematic way except by propaganda in South America, due mainly to the initiative of the National City Bank of New York, but we hope that during the current year more intensive efforts will be made in other parts of the world. As to capital, it is apparent that the enormous export trade, chiefly in grain and munitions, both at high prices, is going to create a vast store of financial energy, which should prove of the most timely assistance in the world-wide industrial competition that is to follow the War. The wealth thus collected should be available for further exploitation in this country itself and for the extension of American enterprise to other regions where attractive opportunities will be afforded, largely by reason of the withdrawal of European initiative in consequence of the War. This applies to mining enterprise more particularly. Let us then consider the effect of the War on the industry in which we—our readers and ourselves—are directly interested.

Unquestionably the demand for metals will be prodigious. Europe has abundant supplies of iron ore and coal, but does not produce sufficient copper, lead, or zinc for her own consumption in ordinary times, much less when an abnormal demand is created, as will be the case when the great work of reconstruction begins in the regions devastated by warfare. Normally the United States consumes all of its lead and nearly all of its zinc, but it exports one-third of the copper extracted from domestic ores, besides nearly as much more from the smelting and refining of foreign ores and mattes, and other forms of copper derived from abroad. The great buyer of American copper is Germany, which consumes 250,000 tons and produces only 25,000 tons per annum. Great Britain and France consume 245,000 tons between them, and produce practically none—about 400 tons per annum. Therefore this country will find a greedy market for the useful metals among the great belligerents, not only now that they are required urgently for the manufacture of munitions but when peace is restored in order to re-build and re-furnish the essentials of modern life.

Another consequence of the War should be the opening of a wider horizon for the American mine operator. Opportunities for using capital productively in mining will be offered in many foreign countries on account of the lack of money for such a purpose in the capitals of Europe. For several years the work of physical reconstruction and industrial rehabilitation will make incessant calls upon the financial resources of London, Paris, and Berlin. There will be some money available for mining, of course, but not so much as heretofore. Speculation in mines abroad will not command European support as it did before August 1914. We believe that this will furnish the American a favorable chance to exploit mineral deposits in Russia, Mexico, South Africa, and South America. The mining capitalist and operator

in this country will find it advantageous to follow the lead of the American engineer and learn to regard mining with a cosmopolitan comprehension, recognizing the fact that this particular industry is the least provincial of all those to which the art of man is applied. Already a start has been made in Russia, Peru, and Chile, for example, not to mention Mexico, where American mining interests have always been large.

Thus we expect to see a notable expansion of enterprise in foreign regions. We anticipate also a great increase of energy and productivity at home, because the demand for the metals to meet domestic consumption and to supply foreign requirements will be increased beyond previous experience. For a while after peace is restored there will be an extraordinary market for American tools and machinery, as well as steel shapes and base metals of every kind. Later there will be less demand for finished products, but a continuing call for the metals themselves. The United States is still a continental area of partly developed and quite unexhausted mineral wealth; being in a state of highly organized industrial vitality, this country can and will furnish a steadily increasing proportion of those metals on which the material civilization of the world depends for its maintenance and progress.

Does the Flag Follow the Trader?

Among the many rumors released by the entrance of an American expeditionary force into Mexico was a story that northern Mexico, to a line going westward from Tampico, was to be sold to the United States for $300,000,000, which, it was mentioned, was a sum sufficient to enable the Mexican government to meet the accumulated claims for damage done to foreign property during the last three years of misrule. This yarn was promptly squelched, but it is interesting as an expression of the hope of the American exploiters of Mexican mineral and agricultural resources. They, naturally, would like to operate under their own flag, with its promise of political stability, instead of trying to do business under a phantasmagoria of government. It seems late in the day to ask the question as to whether they—adventurers, traders, and business men—are warranted in expecting their home Government to go out of its way to protect them in the security of their property or even their lives while on alien soil. Yet this very question has been raised recently by the Commissioner of Immigration in New York, Mr. Frederick C. Howe, who is of the opinion that the flag does not follow an investment, that the United States is not called upon to use armed force to protect the concessions or to collect the debts of American citizens in foreign countries, meaning those backward countries in which security of property is doubtful. American money to the amount of $600,000,000 has been invested in the mines of Mexico; according to Mr. Howe, such capital has been risked without any obligation on the part of the United States government to safeguard its security. This is a strange doctrine. Nor is it in accord with the logic of events. A few weeks ago it was reported on Wall Street that the *de facto* government of Mexico had been refused a loan; we thought we heard a chuckle from the financiers, to whom Carranza is anathema on account of his fantastically radical notions, so completely subversive are they of the *cientifico* activities that flourished in the good old days of Porfirio Diaz! Undoubtedly, if the ideas of the Commissioner of Immigration were to prevail at Washington, it would not be surprising if the financial groups were to make it impossible for General Carranza to raise money to meet obligations already overdue to the extent of at least $70,000,000. Such refusal to finance the *de facto* Government would be awkward but by no means final, for the American government that recognized Carranza would be bound logically to step into the breach itself and make a loan. The fact is not sufficiently recognized that the United States has already established a financial suzerainty over Mexico. This condition has obtained since Huerta was driven out of office by the refusal of the United States to recognize him, and by the subsequent recognition of his enemy, Carranza. No foreign loan could be raised by Mexico without the friendly concurrence of the United States; and in any case no borrowing in Europe is possible at this time. Thus the logic of events has placed the American Government in a position where it controls the credit of Mexico and thereby exerts a decided measure of protection over the property of Americans in that country. Without funds Carranza, or any other President of Mexico, can do nothing. He can get that money only from the banking community in the United States or the government of the United States. But unless subscribers to a loan are promised the protection of their investment it is not possible to obtain the use of such money. Mr. Howe is answered.

The question is worthy of further consideration. We might refer to the pages of history and point to the East India, Hudson's Bay, and British South Africa companies as having advanced under their home government's protection to the successful exploitation of India, Canada, and Rhodesia; but their methods, it may be said, are now out of date. We agree, although it is quite clear that the northern Mexico deal, if true, would have been an illustration of a similar process of benevolent assimilation. A better way is to strengthen and uphold the government of a backward country into which American muscle and money have penetrated peacefully. As the *New Republic* says, "the central motive of a democratic foreign policy must be the modernization of the feeble and distracted nations." When such a country is next door, it becomes all the more obligatory, for our own comfort, to help in the establishment of orderly government, not harrassing it or refusing assistance to it, but supporting it, financially and otherwise, so that it may be established in prosperity. Our people have gone into Mexico to use their capital in working mines, stocking ranges, cultivating farms, building railroads, establishing businesses of every kind, altogether involving about $1,500,000,000; by doing so they have followed the call of legitimate enterprise; their work

has helped to develop the resources of a backward country, educate its people, and promote political development. The political dose was too strong, perhaps, for the peon, but when he has overcome the intoxication of the American idea he will settle down to a quiet citizenship. The American and his property is a fact in Mexico. It is too late to repudiate his obvious claim for protection, always provided he conducts himself properly and does not use his citizenship to make trouble. A policy of detachment will not help either Mexico or Americans in Mexico. The establishment of order is for the good of both. On the other hand, the Americans in Mexico, if they expect the goodwill of either government, their own or that of the country in which they do business, must abstain from intrigues calculated to undermine one government and embarrass the other. No good can come of insidious efforts to force events toward an annexation of northern Mexico; it would entail the bitter enmity of the remainder of Mexico and a recrudescence of suspicion on the part of the Spanish-American countries farther south; it would end all Pan-American fraternization and give the United States a fit of political dyspepsia highly injurious to healthy development.

Electrolytic Zinc

The wet metallurgy of zinc has come very much to the front by reason of the successful application of electrolysis to the precipitation of the metal from sulphate solution. We are glad, therefore, to give our readers an admirable article on the subject by no less an authority than Mr. W. R. Ingalls, the editor of the *Engineering and Mining Journal* and the author of the standard text-book on zinc. The article represents a paper read by him recently before a joint meeting of chemical societies in New York. In our issue of December 25 last we gave the salient facts concerning the big electrolytic zinc precipitation plant now in course of erection for the Anaconda Copper company at Great Falls. This is the result of the successful experimental work done by Messrs. Laist and Frick at Anaconda. These two metallurgists overcame the chemical difficulty of separating the iron so that a purified zinc solution might pass into the electrolytic cell. They discovered that this could be done by using manganese as a carrier of oxygen, whereby the ferrous iron is turned into ferric iron, which is then removed by precipitation. Later the oxygen liberated by the decomposition of the zinc sulphate serves to re-oxidize the manganese so that it is again available for service. In short, this part of the process is cyclical.

Mr. Ingalls takes a conservative view of the future of electrolytic zinc extraction. He does not expect the process to be revolutionary in its effect; on the contrary, he is of the opinion that only metallurgical works operating under exceptionally favorable conditions will be able to continue the use of the process when the War is over and the zinc industry returns to its normal state, which means a price for the metal that is much nearer to 5 cents per pound than to 15 or 20 cents. The electrolytic method calls for cheap hydro-electric power and a relatively high-grade ore, say, 20% zinc. It must be remembered that the natural sulphide, blende, contains only 67% zinc. At Anaconda the separation of the silver is another favorable factor, for it is effected far better by the wet process than by distillation in retorts. Another point may prove important, and that is the comparative purity of the metal produced by electrolytic precipitation. High-grade spelter has been in strong demand for the making of special brasses required in the manufacture of munitions, and it may be that one of the results of the War will be to place such a premium on the purer brand of spelter as to give it a persistently preferred market. Another recent development, namely, the growing production of a high-grade concentrate (say, 50 to 55% zinc) by flotation, favors the electrolytic method of reduction, because the excessive fineness of the flotation product causes difficulties in smelting by the old distillation process. That is one reason why so many smelting companies have started to make zinc electrolytically. Besides the Anaconda company's big plant at Great Falls and the smaller one at Anaconda itself, we may mention the production of electrolytic zinc at the Trail smelter of the Consolidated Mining & Smelting Company of Canada; the Electro Zinc Company at Welland, Ontario; the plants at Keokuk, Iowa, at Bully Hill and Palo Alto, California; and now the announcement that $1,000,000 is to be spent on a similar annex at the Garfield smelter, of the American Smelting & Refining Company, in Utah. While deferring to Mr. Ingalls' special knowledge of the subject, it seems fair to recall the fact that he has never taken a particularly cheerful view of the development of this phase of zinc metallurgy, and it is obvious that the big smelting companies, by spending millions of dollars in the building of reduction works using this process, are, in effect, betting a large sum that it will prove successful not only during the War period, but afterward in normal times. It seems to us that there are several factors favoring the electrolytic method, particularly where electrical energy is available on reasonable terms, say, $30 per kilowatt-year, equivalent to about $22 per horsepower-year. We believe that power at that price will be obtainable for the purpose, but in California all power contracts are subject to revision by the Railroad Commission, which is authorized to prevent an inequitable distribution among consumers. We hazard the prediction that electrolytic spelter will be produced at a total cost of 3 cents per pound, allowing $3 per ton for mining, where crude ore runs from 15 to 20% zinc. This would be about 25% cheaper than production by the old method, which we debit with an average cost of 4 cents per pound of zinc. In any event, the new development—for it is hardly a new process—does challenge the old retort practice of Silesia and Belgium, and threatens these European zinc-smelting centres with serious competition. Perhaps, as a factor in zinc reduction, the waterfalls of Norway will prove superior to the coalfields of Belgium, and the energy of the Missouri may prove preferable to the oil of Oklahoma.

DISCUSSION

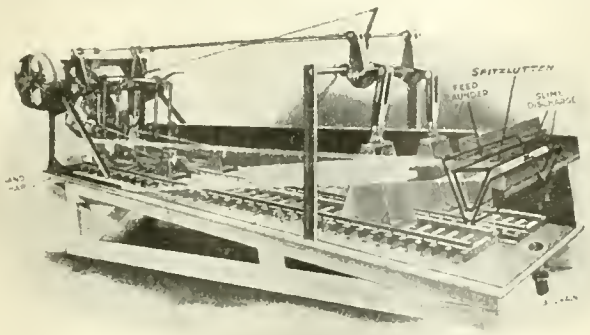
Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Classification and Fine Grinding

The Editor:

Sir—In your issue of December 18, A. L. Blomfield has given some interesting figures (in reply to my letter of October 16) regarding the recent operation of the Dorr classifier in connection with ball-mills at Anaconda and Inspiration.

According to the screen analysis given, the classified oversize sand contains 28.8% of –48 mesh and 71.2% of +48 mesh product. The overflow product for treatment will practically all pass a 48-mesh screen. According

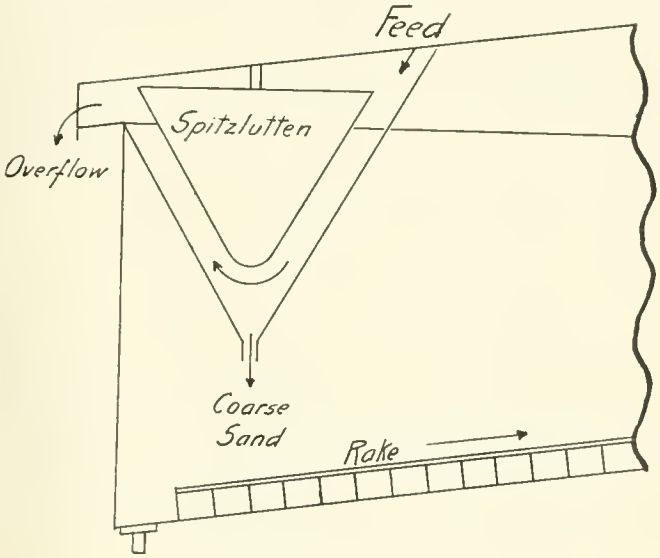


SPITZLUTTEN WITH DORR CLASSIFIER.

to this there is a large proportion of –48 product already fine enough passing to the ball-mills that should have overflowed the classifier with the finished product. I suppose at the Inspiration they are using the baffle as well as an increased speed for the rakes in order to obtain this result. The efficieney of the ball-mill should be increased by eliminating from the feed the greater part of that 28.8% of –48 mesh material.

I suggest as a means for largely reducing the amount of undersize (–48 mesh) product from the feed, the use of a spitzlutten classifier in combination with the Dorr machine. This would convert it into a combined hydraulic and rake classifier. Very little water, if any, would be required for the spitzlutten, as it would be submerged to its overflow within the Dorr machine. By raising or lowering the inner prism of the spitzlutten, one can overflow any product desired for final treatment without speeding up the machine or using spray-pipes at the sand-discharge end. I believe that the Homestake has also used a similar arrangement thereby minimizing the return of undersize material with the feed to tube-mills.

The Dorr classifier is an excellent machine for separating –150 or –200 mesh products from sand. The mill of the Frontino & Bolivia Gold Mining Co. in Colombia for which I recently designed and erected a cyanide plant, consists of classifier, agitators and thickeners all of the Dorr type (counter-current decantation) for slime of –150 mesh, and leaching-vats for sand of +150



DETAIL OF ARRANGEMENT.

mesh. The sand-vats also act as clarifiers for the continuously decanted gold solution from the thickeners. The classifier delivers a clean product practically free from slime to the sand-treatment vats.

La Salada, Colombia, January 24.

Treatment of Antimony-Gold Ore

The Editor:

Sir—I recently came across the following notes on a mill-test that I made some years ago in southern Mexico.

The ore in question carried gold and silver. Associated minerals were antimony, lead, arsenopyrite, and copper. The practice had been to crush in a stamp-mill, with a large plate-area, then concentrate, and ship the product. The tailing, after passing over amalgamating plates, contained a considerable amount of free gold which was plainly visible in a pan, and also carried such a high percentage of antimony that the cyanide consumption was prohibitive. The mill-men insisted that the free gold in the tailing was not gold at all, only a form of mica, because it would not amalgamate with

mercury, but a fire-assay disproved this idea. A chemical analysis led to the discovery that this gold was covered by a film of antimony sulphide (stibnite) and that this was soluble in a solution of caustic soda. After this treatment the gold readily amalgamated with mercury. I also found that by treating the original ore with a strong solution of caustic soda and washing well, it cyanided easily with a consumption of but 2.6 lb. cyanide per ton of ore.

The ore was crushed in a 5% solution of caustic soda, amalgamated on copper plates for the free gold, and then concentrated. The tailing from the concentrating tables passed through a long box with a traveling belt, which separated the sand from slime. The fine was afterward dewatered in a spitzkasten and the water returned to one of two battery storage-tanks, where the antimony was precipitated. The soda solution was then brought up to strength and used over again. The sand was cyanided by percolation and the slime by agitation and decantation. The copper, which went into solution, was taken care of by immersing the zinc shaving in a 10% solution of lead acetate. The lead only caused trouble by keeping the amalgam soft. This was afterward overcome by maintaining the plates dry.

WM. SEWARD MANN.

Cananea, February 20.

This is an interesting note. We recall that at West Gore, in Nova Scotia, in 1905, an antimonial-gold ore was treated by dissolving the stibnite in a dilute solution of caustic soda and then neutralizing so as to precipitate the antimony form of red amorphous, Sb_2S_3. The intention was to cyanide the gold, but the difficulty arose of getting rid of the soda before cyaniding.—EDITOR.]

Electrolytic Zinc

The Editor:

Sir—A year or two ago there was prevalent the idea that the making of electrolytic zinc through some hydrometallurgical process was not commercially practicable, and would never compete with pyro-metallurgical processes. Owing, however, to the high price of zinc, and especially to the high charge made for the treatment of zinc ores, the electrolytic recovery of zinc is being seriously undertaken—as, for instance, at the Washoe plant, Anaconda, where a 10-ton experimental plant is now in operation.

It is true that patents are obtainable for presumably novel details of treatment, but it is questionable whether these patented details would stand the test of legal action. These are so largely adaptations taken over from other chemical processes and from cyaniding that their novelty is in doubt.

The Nahnsen process, modified in detail, is at present preferred. This may be thus described: The finely ground ore after roasting is brought in contact with the liquor from the electrolytic tanks now containing free sulphuric acid and from which a part of the zinc has been removed, having been deposited on the cathodes. The zinc (and other bases) is extracted by the action of the acid solution; the resultant solution is neutralized and treated in tanks with zinc dust for the precipitation of any electro-negative constituents that may be present, and after chlorination is sent in a regular stream to the electrolytic tanks.

The whole process consists then of two phases: First, the zinc-containing electrolyte is decomposed in the bath, yielding zinc and producing free sulphuric acid. Second, this acid liquor still containing zinc sulphate, goes to the dissolving-tanks, where it takes up all the zinc possible. In order that the solution may be free from iron, it is brought in contact with ores containing increasing percentages of zinc, so that any iron oxide may be precipitated rapidly by the zinc oxide. Any other bases are precipitated later by means of zinc-dust, leaving a nearly pure solution of zinc sulphate for treatment in the electrolytic tanks.

As for details of precipitation, numerous experiments have been instituted, all of which have been tried in present practice. Otto Best has lately patented the idea of neutralizing any free acid immediately after solution by the use of a regulated addition of lime. The oxidation of the ferrous iron by potassium chlorate, by manganese, etc., has also been patented. All of these people endeavor to obtain a neutral and pure zinc sulphate solution to send to the electrolytic bath. They try to dissolve as little of the other bases as possible by promptly neutralizing the free acid. Metallic zinc, I may add in passing, is difficult of solution in strong sulphuric acid, though it makes quite a display of so doing.

One could wish that the idea of patenting could be abandoned and that the various companies, now so intent on the problem of producing pure electrolytic zinc, could compare experiments to their mutual advantage. Re-melted electrolyic zinc is of a pure white color like nickel, 99.92% fine, and fetches the highest price on the market.

Salt Lake City, March 2. L. S. AUSTIN.

Use for an Old Hammer Drill

The Editor:

Sir—I note in your issue of April 3, 1915, the use to which Mr. C. A. Banks puts an old hammer-drill. We have also found the idea helpful, having had occasion some years ago to employ a drill in the manner described. Within the last year we have rigged up an old Leyner drill as a pneumatic stamp, the mortar-box being cut out of a suitable piece of timber and lined with ¼-inch steel. A launder conveys the crushed ore to a small Wilfley table. Sizing tests on the discharged pulp closely parallel the regular discharge from our gravity stamps.

PAUL W. AVERY.

El Oro, Mexico, January 24.

WHEN selenium minerals are heated on charcoal before the blowpipe, they give off a peculiar fetid odor, like that of carbon di-sulphide.

The Nevada Wonder Pipe-Line

Automatic Devices for Checking Interruptions to Service

By J. A. Burgess

A GEOLOGIST, in writing of the mineral resources of California, mentioned water as the most important mineral. It is not usual to think of water in this way, but the geologist's remark was strictly true, and would apply with equal force to the entire world. The truth that he stated is most appreciated in localities where water is scarce; and in the oases of the arid regions, where industry depends on a scanty water-supply, it is not uncommon to hear recognition of the fact openly expressed.

An ample supply of water is particularly necessary for mining and milling plants and in some localities it has to be brought for a great distance at big expense. Any interruption of the supply causes a corresponding cessation of milling operations, and therefore every possible preeaution should be taken to insure against such a contingency. This paper describes the means used for this purpose at the Nevada Wonder mine, at Wonder, in Churchill county, Nevada.

The pipe-line was laid in the latter part of 1910. It conveys water by gravity-flow from Horse creek to the mine, a distance of 10 miles. It is in the form of a broad letter U. From the point of intake the course of the line leads downward through a valley until a point 2135 ft. below the intake is reached; thence it rises to the storage-tanks at the mine, where the elevation is only 465 ft. lower than the intake.

The line is built of standard, guaranteed full weight, steel pipe, with screwed joints. The same kind of couplings are used as on extra heavy pipe. The flanges and valves of the original equipment were of the type known as 'hydraulic,' but on all subsequent repair-work 'ammonia' flanges were used. The pipe was dipped in asphaltum before shipment by the manufacturer. The diameter at the intake is 6 in., reducing to 5 in. at 500 ft., and to 4 in. at 1000 ft. It has a covering of from 10 to 18 in. of soil. Air-valves and drain-valves are placed

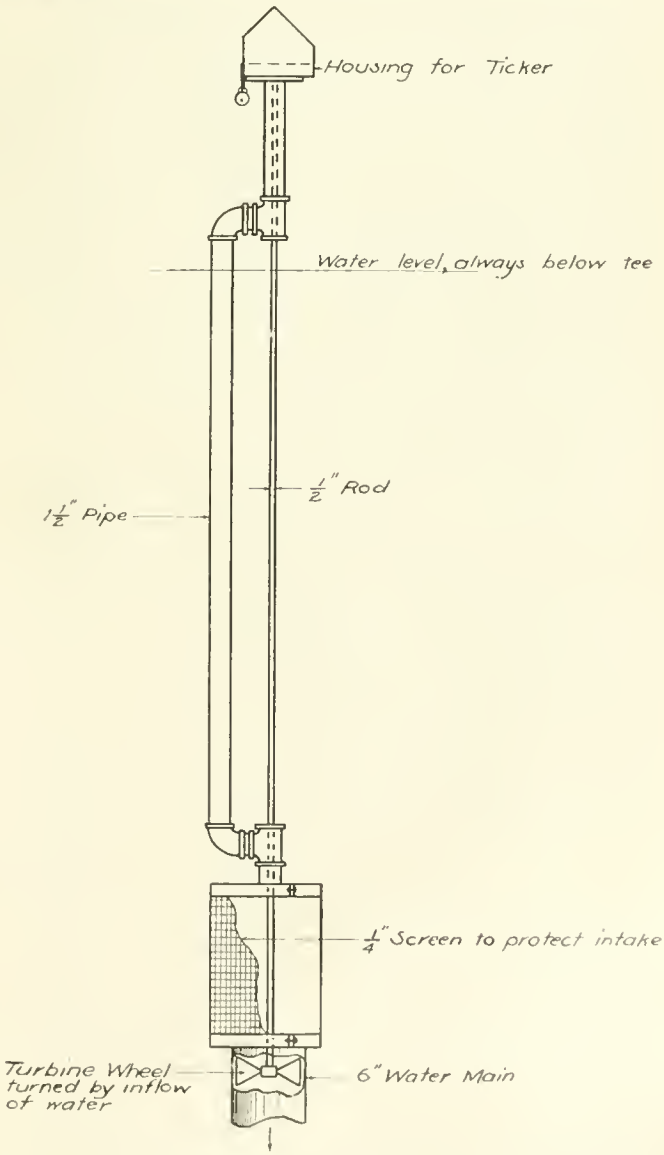

FIG. 3. TELEPHONE FLOW-INDICATOR FOR INTAKE OF WATER-MAIN.

at all peaks and sags where air or sand might collect. These are also of use when it becomes necessary to drain the pipe line. They are one-inch hydraulic-compression valves, and there are 46 of them on the line. Shut off valves are placed at four important points. The pressure at the lowest part of the line is 920 lb. per square inch, and an automatic valve, set to release at 1000 lb. pressure, is situated at this point to protect the pipe from sudden increases of pressure due to water-hammer from the too sudden closing of a valve.

The calculated capacity of the line is 185,000 gallons per 24 hours, and this checks fairly closely with the actual delivery. The rate of flow in the pipe is 2.57 ft. per second.

The chief sources of trouble are clogging of the intake-screens by leaves, breakage of the pipe at joints by longitudinal contraction in cold weather, pitting by corrosion, stoppage of the flow in the creek by freezing, and freezing of water in the pipe. Uncovering of the line is brought about by cloud-bursts, by cattle using the mound for a trail, and by badgers digging off the covering, evidently mistaking the sound of flowing water for the noise of insects or small burrowing animals.

The obvious remedy for clogging of the intake by leaves is to have the screens cleaned frequently. The interval between cleanings can be kept within reasonable limits by having the screen-area sufficiently large. Contraction breaks at joints, though never frequent, gave more trouble during the first three winters than since then. They took the form of cross breaks at the threaded ends. The adjustment of irregular strains and the elimination of weak spots by breakage and repair put an end to the trouble. There are no expansion-joints in the line; the numerous bends would make them superfluous. Pitting of the pipe has caused no trouble except in the valley, where the pipe was penetrated several times in the fourth year. These breaks occurred within half a mile of each other, and were doubtless due to an excess of alkali in the soil. The pitting was from the outside. A protective coating applied to the pipe at the time it was laid would have prevented this deterioration, but the coating applied by the manufacturer before shipment was partly rubbed off during transportation.

Excessively cold weather forms the principal source of danger. With the thermometer not lower than 10° or 15° F. at night the line is safe. With temperatures between 10° and 5° above zero, the line must be watched closely, and when the night temperatures are below 5° it is in danger. The lowest temperature recorded in five years was −11°. During the present winter freezing began in the pipe after three nights with the temperature at 4° below zero. At this low temperature the rate of flow in the line is not sufficient to prevent the formation of ice. A good covering of snow on the ground acts as a blanket and greatly reduces the danger of freezing. The ends of the line, being at the higher altitudes, are in the greatest danger of freezing; and when a decrease in the flow is observed during a cold snap, the means used to prevent a total closure of the line is to increase the rate of flow at the intake end by opening valves in succession from the delivery end, until a point of high pressure has been reached. It has been found that ice formed in the pipe can be rapidly cut out by increasing the flow in this way. While this is being done the delivery end of the line is drained, and no water reaches the mine; but the cold spells usually last only a few days and it is better to endure a temporary shortage than to have the line frozen. There is storage capacity at the mine sufficient to run the mill for three days.

During normal winters Horse creek carries less than twice the quantity of water taken, and during an excessively cold night there is danger of the creek being completely stopped by freezing. The only way to save the line in a case of this kind would be to drain it entirely.

During the unusually cold winter of 1912-'13 this line, like many others in the West, experienced disaster, and the experience of that winter suggested steps to prevent a repetition of the trouble. Considerations of expense and the necessity for maintaining a continuous water-supply prevented the deepening of the trench, but additional covering was mounded over the pipe. A telephone line was built from the head-gate to the mine, several permanent telephone stations were established, and two portable sets were provided. A flow-indicator was devised and placed at the intake, arranged so that the rate of flow could be approximately read at any telephone-receiver. A device was attached to the mine end of the line to give instant warning of a stoppage of the flow. Arrangements were made to keep a watchman at the head-gate during dangerously cold weather, and a typewritten program covering every possible contingency was furnished to him, as well as to a rancher three miles below the intake, and to several employees at the mine. This program specified exactly the duties of each man in case of a threatened freeze-up, and provided for the complete draining of the line, if necessary, within an hour after receiving warning. All telephone-poles and valve-boxes were marked with consecutive numbers.

The arrangement of the head-gate and the mechanical protective devices are as follows: Fig. 1 shows the arrangement of the head-gate and the settling-tanks. The dam backs up water to a depth of two feet. Removable boards, set horizontally in grooves, afford a means of sluicing out gravel accumulated during freshets. The entire bottom of the canyon is formed of loose rock-debris and soil, and the grade is so steep that a storage-dam would be impracticable; and in addition to this the danger of cloud-bursts forms an objection to the erection of expensive headworks. For these reasons no improvements beyond those strictly necessary were made. The intake at the dam is arranged to give a constant water-level, and to take the water from a depth of 12 inches below the surface. By these means a considerable depth of ice on the dam does not interfere with the flow into the pipe, as long as there is running water in the stream. As an additional protection, the dam is boarded over in winter. Ample area of screen, ¼-inch mesh, is shown sur-

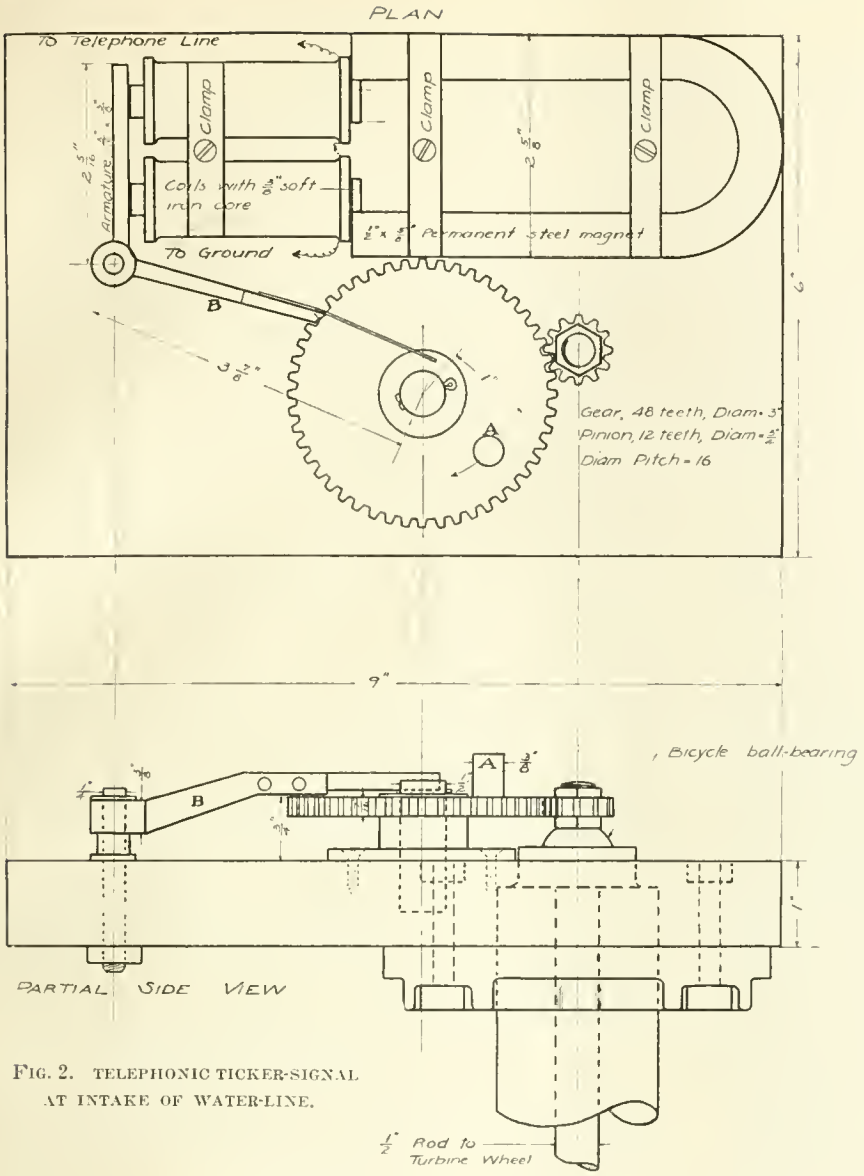

FIG. 2. TELEPHONIC TICKER-SIGNAL AT INTAKE OF WATER-LINE.

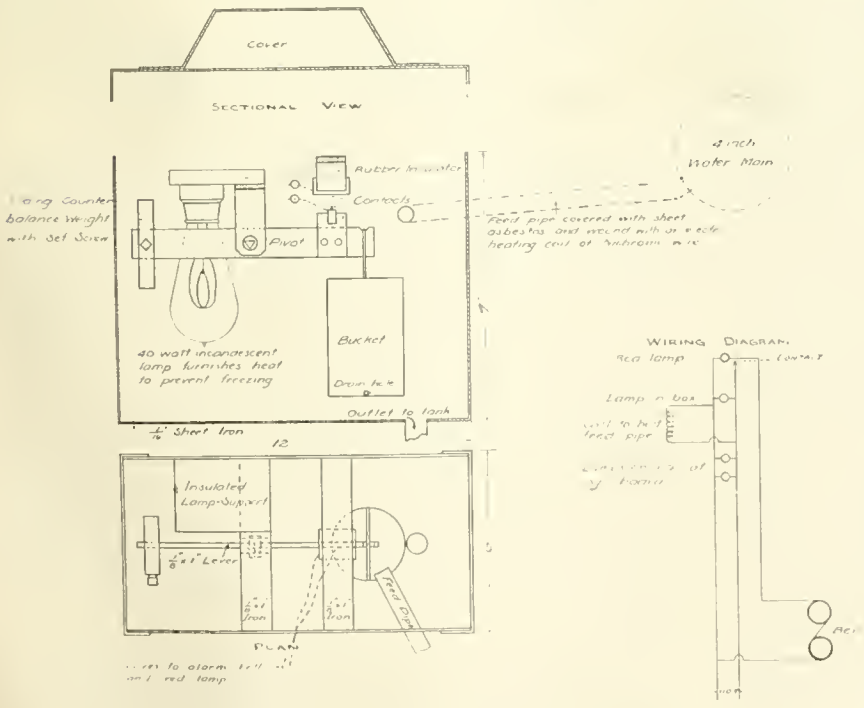

FIG. 4. SIGNAL ON WATER TANKS, NEVADA WONDER MINING CO.

rounding the intake. Two small tanks are provided for the purpose of trapping sand. The first has a conical bottom, and both are furnished with discharge plugs operated from above by threaded rods. Both tanks are covered. They are placed at the side of the canyon where only an unusually heavy cloud-burst would damage them. Delivery from the dam to the tanks was originally made through a square wooden flume, but when this became leaky, galvanized sheet-iron pipe was laid inside of it.

In Fig. 2 and 3, are shown the details of the telephonic flow-indicator, commonly called a 'ticker.' It consists essentially of a turbine-wheel just inside of the intake end of the water-main, by means of which the armature of a permanent magnet is periodically removed from its poles. The interruption of the magnetic flux induces an electrical impulse in a coil about the magnet. The coil is grounded at one end and attached to the telephone wire at the other, and each movement of the armature produces a clicking sound in the telephone receivers that is easily heard but is not sufficiently loud to interfere with conversation. The telephone line is connected with all the company telephones, so that the indicator may be heard in all offices and residences. The operation of the ticker is readily understood from the drawing. At each revolution the pin *A* displaces the arm *B*, which is integral with the armature. The bicycle ball-bearing forms a thrust-bearing that supports the entire weight of the rod and turbine-wheel, so that the lower bearing of the turbine-rod is simply a loose guide-bearing, and requires no lubrication. The only attention required by the ball-bearing for the past two years has been a few drops of oil occasionally. Its housing is kept locked. The support is made of pipe, but the drive-rod passes through only a part of its length. We ascertained that occasionally accumulations of air in the pipe-line bubbled back to the tank, and when a straight support was used, the gurgling air-bubbles entered the support and drove water upward through the bearing into the ticker. In cold weather this water froze and stopped the apparatus.

Fig. 4 shows the warning apparatus attached to the delivery end of the pipe-

line at the storage tanks. A small tin can with several punctures in the bottom is attached by a bail to a beam. The beam is supported by a pivoted axis like the beam of a pulp balance. The bucket when empty is over-balanced by a weight at the opposite end of the beam, so that the bucket end rises and an electrical contact is made. When the bucket is full of water it over-balances the weighted end and the contact is broken. A bleeder pipe, ½-in. diam., taps the horizontal part of the water-main where it discharges into the tank, and leads to the bucket. When water is being delivered into the tank a small stream flows continuously into the bucket of the alarm apparatus, and the electrical contact is held open. If the water ceases to flow in the main pipe, none is delivered to the bucket and its contents leak out through the holes in its bottom. This permits the bucket end of the beam to rise, and the electrical contact thus established simultaneously lights a red incandescent lamp on the tank, and operates a loud-ringing polarized bell at a place in the mill where a mill-hand is always within hearing distance. To prevent freezing of the apparatus and of the small pipe leading to it, an incandescent lamp is kept lighted within the box, and a heating-coil is placed around the bleeder-pipe. Lights are maintained on the boards on which the water-level of the tanks is indicated, so that they may be read at night. The wiring diagram is shown in Fig. 4. A 110-volt alternating current is used. It will be observed that the bleeder-pipe does not tap the water-main exactly at the lower side. This is so that the alarm will be given when there is a serious decrease in the flow, and before it stops entirely. The apparatus is inspected and the bucket cleaned daily during cold weather. Small solid particles or scales from the pipe sometimes gather in the bucket and stop up the holes unless this is done.

The ticker is the pulse by which the performance of the water system may be watched. Under normal operating conditions it sounds 24 times per minute. If it works faster than this, it is a certain indication of either a break in the line or an open drain-valve. If the ticker sounds less than 24 times per minute, the reduction is due to decreased flow and may be caused by several circumstances. Except in freezing weather, it is apt to be caused either by air or sand in the pipe, or by leaves partly clogging the screens at the intake. In very cold weather it may be caused by a shortage of water in the creek or by freezing in the pipe. Only an inspection of the intake will distinguish between these possibilities, and it is partly for this reason that a watchman is kept at the head-gate during cold weather. At such times the temperature of the water in the stream is at 32°, and even a short stoppage of the flow in the pipe would result in a freeze-up. It is necessary, therefore, to obtain prompt information of conditions at the head-gate when there is any decrease of flow in the line. The alarm apparatus at the storage-tanks gives notice of any serious decrease of delivery, whatever the cause. By means of these two devices, and with a reasonable amount of attention, the danger of a freeze-up has been practically eliminated.

The ticker is also of great help when water is being forced through the line after draining it in cold weather. By using a portable telephone, the working crew can observe any stoppage that might be caused by the freezing of undrained pockets of water. In such a case the first valve back of the obstruction should be opened to maintain the flow until the obstruction is removed. Great care is taken under these circumstances to maintain a continuous flow.

The ticker is susceptible of use for a variety of purposes. By it the speed of operation of any piece of machinery can be indicated through a telephone line.

A few notes on methods of repair may be of interest. In thawing the line after the freeze-up of 1913, it was found that running a stream of water through the ditch, where this could be done, thawed the pipe just as effectively as a fire. When frozen only in isolated spots, the trouble can be easily detected between two valves. To determine the exact spot, the pipe is dug up at intervals, and tapped by boring holes 15/32 in. diam. When the obstruction is removed the hole is threaded and closed with a ½-in. plug. The flanges used in the construction of the line were faced flat, and where these were subjected to high pressure, trouble was experienced through the blowing out of gaskets. In all repair-work, heavy ammonia flanges are used. In these fittings the faces are made in matched parts. On one face there is a projection ½ in. wide and ¼ in. high, and on the opposite face there is a groove of corresponding dimensions, in which is placed a fiber gasket $\frac{1}{16}$ in. thick. Heavy fittings of this kind are peculiarly suited to repair-work, since their construction allows of using a heavy strain on the bolts to overcome a slight error in cutting inserted lengths. It is now planned to avoid the trouble caused by the freezing of small pockets of water after partly draining the line, by blowing out the residual water with air from the air-compressor at the mine.

Manganese in Panama

According to a Consular report from Colon an American syndicate recently opened a manganese mine at Madinga, on the gulf of San Blas, in the province of Colon, about 70 miles east of the city of Colon. A trial shipment of 900 tons of the ore has been made to New York. One of the owners, who acts as agent for the syndicate, states that shipments of 1500 tons a month can probably be made for several months if vessels are available for that purpose; but beyond that nothing definite can now be stated regarding the development of the mine. A wharf at deep water has, however, been built near the mine, and if the supply of ore holds out, and it can be profitably marketed it is the purpose of the owners to develop the Madinga mines to a considerable extent.

QUICKSILVER deposits in the Huancavelica district of Peru have changed hands, and mining is to be resumed by E. E. Fernandini of the American Vanadium Co.

Electrolytic Zinc

By W. R. Ingalls

*INTRODUCTORY. Without any doubt, the most important thing in the metallurgy of zinc in 1915 was the inauguration of electrolytic zinc production direct from ore on a large experimental, even a commercial, scale at several places, the most important of these being at Anaconda, Mont., where the production of electrolytic spelter at the rate of about 5 tons per day was begun. The results are considered so favorable that the Anaconda company has commenced the erection at Great Falls, Mont., of a plant capable of producing 35,000 tons of electrolytic spelter per annum.

CHEMISTRY OF THE PROCESS. The chemistry of the process used at Anaconda is described in U. S. Pat. No. 1,167,700, granted to Frederick Laist and Frederick F. Frick, Jan. 11, 1916. According to this the proper performance of the cycle depends upon the presence of manganese. Its function is to serve as a carrier of oxygen for the oxidation of ferrous to ferric iron, thus rendering possible a complete separation of iron and affording a purified solution from which zinc may be recovered by electrolysis. In the course of this electrolysis the manganese is restored to a state of oxidation higher than the manganous state, and thereby becomes available for re-use in the process.

The calcined ore is treated at a temperature of 50 to 65° C. with sufficient dilute sulphuric acid so that there is 5 to 10% excess acid over that required to complete the reactions, by which the metals in the calcined ore are dissolved. A portion of the iron enters into solution as a ferrous salt, in which state it is not completely removed by the usual basic precipitants (lime, zinc oxide, etc.) It is necessary, therefore, to oxidize this ferrous iron, and in the cyclic operation of the process this is accomplished through the agency of the manganese, which enters the cycle at this point in one of its higher states of oxidation—as for instance, in the form of manganese dioxide. The oxidation of the ferrous sulphate takes place according to the equation,

$$2FeSO_4 + MnO_2 + 2H_2SO_4 = Fe_2(SO_4)_3 + MnSO_4 + 2H_2O$$

Having accomplished the leaching and having a slight excess of acid solution, sufficient milk of lime or zinc oxide is added to render the solution neutral or slightly basic. The iron and most of the other impurities except copper are precipitated, and the precipitated impurities are so coagulated that filtration is very rapid.

The solution, purified from elements harmful to electrolysis, is subjected to electrolysis using insoluble anodes—as lead, for example—and suitable deposition blanks or zinc starting sheets for cathodes. The electrolytic reactions are:

$$ZnSO_4 + \text{current} = Zn + SO_4$$
$$SO_4 = SO_3 + O$$
$$SO_3 + H_2O = H_2SO_4$$

The oxygen liberated from the SO_4 at the anode effects the oxidation of the manganese; thus,

$$2MnSO_4 + 2O + 6H_2O = 2HMnO_4 + 2H_2SO_4$$
$$2HMnO_4 + 3MnSO_4 + 2H_2O = 5MnO_2 + 3H_2SO_4$$

It is apparent from the foregoing that a regenerated sulphuric-acid solution containing manganese in higher stages of oxidation than the manganous state results and is directly available for leaching additional portions of roasted ore, where the higher oxides of manganese are available for oxidation of ferrous iron and are themselves reduced to manganous sulphate, thus making a cyclic process in which the desirable manganese may be used over and over again and in which the original supply or any deficiency may be supplied to the raw zinc ore or concentrates in the form of carbonate or sulphide ores of manganese.

DETAILS OF THE PROCESS. In the performance of the process the ore is roasted in Wedge furnaces at a temperature of 900° C., which, with a fuel consumption of 5 to 6%, delivers a product containing only about 0.3% S as sulphide. The roasted ore is leached in a Pachuca tank with air agitation, the lixiviant being spent solution from the electrolytic cells. The percentage of zinc dissolved is from 85 to 95. After addition of limestone to neutralize free acid, the pulp is run to a battery of Minerals Separation flotation agitators, where it is agitated and aerated to precipitate ferric hydrate. The charge thence passes to a Dorr thickener, which delivers clear overflow to solution storage tank and mud to Oliver filter. The latter gives cakes of gangue containing iron, lead, silver, etc., which go to blast furnaces, and solution which is united with that overflowing from the Dorr thickener.

From the solution tank the liquor is drawn into a tube-mill filled with zinc balls, which precipitate copper and cadmium, flowing thence to a circular filtering tank having a quartz bottom, and finally to a Shriver plate and frame filter press, which completes the clarification. The purified solution goes to a cascade of 21 electrolytic cells, whereof there are two series, and upon entering, is mixed

*A paper presented at a joint meeting of the New York Sections of the American Electrochemical Society, the American Chemical Society and the Society of Chemical Industry, on February 11, 1916, but somewhat further elaborated for the *Engineering & Mining Journal*, of which the author is Editor, in its issue of March 4, 1916.

with one-half of the spent electrolyte from the tail cells, which brings the cell feed up to 2½% free H_2SO_4 and 5% Zn.

In flowing through the cells the temperature of the electrolyte is kept below 70° C. by means of lead coils conducting cooling water, which is done in small boxes interposed between the cells. The anodes are of pure lead, the cathodes of aluminum. Solution is electrolyzed at a current density of 23 amp. per sq. ft., the voltage drop being 3.8 to 3.4 volts per cell, decreasing as the acid increases. Current efficiency is 93 to 94%. The cathode is finished within 48 hr., by which time it has attained a weight of 50 lb. and is then peeled from the aluminum sheet.

Apart from the Anaconda work, the most ambitious plans carried on in 1915 were those of the Consolidated Mining and Smelting Co. of Canada, which continued the experimental work begun several years ago. In the last official report of this company it is stated that spelter of good grade has been produced at the rate of 1000 lb. per day from ore from the Sullivan mine, and that the results were sufficiently promising to warrant the building of a plant capable of producing 25 to 35 tons of spelter daily. Construction of this plant is well advanced, and it is expected to be in operation early in 1916.

Electrolytic zinc was also produced in 1915 on an experimental scale by the Electro Zinc Co. at Welland, Ontario, while some work in this line was done at Keokuk, Iowa, and at Bully Hill, California, and there were one or two other operations (one of these employing the Isherwood process) that may not yet be mentioned publicly. The work at Welland is unique in that the dissolving of the zinc and the electrolysis of the solution are performed in the same vat, the cathodes being inclosed in canvas bags. All of the other work, so far as I know, is being done on lines similar to those at Anaconda.

Before going any further, let it be well fixed in the mind that the conditions that have existed in the zinc industry during the last year are not only unprecedented, but also it is certain that they cannot be otherwise than ephemeral. They have been due to a shortage of metallurgical capacity, not of ore in the least degree, and that shortage is being reduced with extraordinary rapidity. In the meanwhile, however, there has naturally been a huge metallurgical margin—even $60 per ton of ore against a normal of about $15—in the manufacture of common spelter, and with such a margin it has been good sense not only to commit metallurgical crimes, but also to institute new processes that would not ordinarily be profitable. In the manufacture of high-grade spelter the margin has been much higher, so much so that the possibility of it would two years ago have been considered nothing less than preposterous.

Now, the electrometallurgy of zinc is no new thing. The electrolytic refining of impure spelter was tried on a large scale by Nahnsen in Upper Silesia in the 90's, the hydrometallurgical-electrometallurgical treatment of zinc ore was essayed disastrously by Ashcroft at Cockle Creek, N. S. W., in a works costing about one million dollars. Doctor Hoepfner developed a process that was put into use at Fuhrfort on the Rhine and at the works of Brunner, Mond & Co., at Winnington, in England. At the former it was abandoned after a short time; at the latter it has been continued through a long series of years, making a few hundred tons of spelter annually, and is in use at the present time. The electrometallurgy of zinc has therefore a commercial history of respectable antiquity.

Difficulties in the Art. In the early days of the art, both commercial and experimental, difficulty was experienced in obtaining dense deposits on the cathodes, spongy zinc being a stumbling block, but while this matter required some study for its mastery, it was manifest that the real difficulties of this process were the getting of zinc into solution rather than out of it and the large amount of power required for zinc precipitation.

With regard to the former point, I refer to the formation of insoluble ferrite of zinc in roasting, with the consequence of relatively low extraction of zinc. That is experienced in the case of many, perhaps most, ores that it is desired to treat. To illustrate, roasted Joplin blende may be leached with sulphuric acid so as to cause it to give up 97 or 98% of its zinc, the residue being a white silica sand, but nobody wants to treat Joplin ore by a hydrometallurgical process, for the reason that it would be less economical than ordinary smelting. On the other hand, certain mixed ores high in iron, like those of Leadville, Colorado, may give up only about 65% of their zinc. So low an extraction would in itself be prohibitive in most circumstances in ordinary times. It is possible that the roasting might be conducted in such a way as to steer clear between the Scylla of zinc ferrite on the one hand and the Charybdis of undecomposed zinc sulphide on the other hand, but that question has not been investigated with definite results, so far as I know. With regard to the high power required for the electrolysis of zinc solutions with insoluble anodes, the expense of it, when imposed upon the cost of roasting, leaching, re-melting cathodes, re-working between products, etc., is likely to make the cost of hydrometallurgical-electrometallurgical zinc extraction too high to be ordinarily considered.

I have therefore repeatedly expressed the opinion that metallurgical processes of this sort were unlikely to be successful commercially, unless: (1) Exceptionally cheap hydro-electric power, such as the $6 or $7 per annual horsepower of Norway and Sweden, were available; or (2) unless use could be made of the anode reaction, such as the liberation of chlorine by the electrolysis of a chloride solution and the employment of it for some chemical manufacture, as at Winnington, England; or (3) unless certain especially favorable conditions otherwise existed. By the last I mean such things as high-grade of the run-of-mine ore, a kind of ore that will give up a high percentage of zinc by lixiviation with sulphuric acid, an ore high in silver and possibly lead.

These points are almost determinative. In the pyrometallurgy of zinc the extraction of silver is, perhaps, about 65%. In the hydrometallurgy of zinc it ought to be upward of 90%, perhaps as high as 95%. The situation with respect to lead is somewhat similar. It is needless to dwell upon the importance of this in the cases of ore exceptionally high in silver.

Favorable Conditions at Butte. Now, in the treatment of the Butte ore at Anaconda, about all of the favorable conditions that I have enumerated under the third head exist. The ore raised from the mine is of rather high grade, it is of a character that enables 90% of the zinc, or more, to be extracted by sulphuric-acid lixiviation, and as zinc ores go, it is exceptionally high in silver (the concentrated ore going 20 oz. silver per ton or thereabouts). Moreover, the Anaconda company is introducing zinc extraction in connection with its other great metallurgical work, thus dividing general and administrative expenses, etc. It is able to obtain moderately cheap power at Great Falls, and finally, what is not least in importance, it possesses about the best metallurgical organization of any concern in the United States and is instituting this new process at a time when there ought to be commercial profit in spite of any imaginable infantile disorders. I am not free to communicate such figures respecting the Anaconda results as I know, but I may say that the Anaconda management is thoroughly aware of the exceptional conditions existing in the zinc industry at present, and is nevertheless of the opinion that with its peculiarly favorable circumstances it can continue the production of electrolytic zinc in competition with everybody else in normal times, or even in the hard times that may be experienced after the termination of the War. The promise of the development of the hydrometallurgy-electrometallurgy of zinc as a commercial art on a large scale has therefore already become a prospect. There is to be such an art. The magnitude that it will attain and its effect upon the zinc industry of the world remain for the future to tell, but that it is going to have an early and important influence is not to be doubted.

Turning attention to some of the technical features of electrolytic zinc production, the conditions governing the electrolysis of zinc solutions were exhaustively treated by Dr. Victor Engelhardt in a paper read at the first general meeting of the Gesellschaft Deutscher Metallhütten- und Bergleute and published in *Metallurgie* a few years ago. A summary of Doctor Engelhardt's conclusions, together with some additional notes, was published by Prof. J. W. Richards in 'Transactions of the American Electrochemical Society,' XXV, pp. 281-90. The ideas of Doctor Engelhardt, who is chief engineer of the electrochemical division of the Siemens & Halske company, of Berlin, are exemplified in what are called the Siemens & Halske and Isherwood processes. However, in the late development of zinc electrolysis, 'processes' and patents have played but slight part. With recent experimenters the matter of spongy-zinc deposits appears to have been among the least of the difficulties. Mr. Keating succeeded several years ago in depositing smooth, solid zinc on his cathodes at Bully Hill, California, while as for Mr. Laist, he accomplished this part of the process as a matter of course, just as simply as if he were depositing copper, the necessary precautions as to purity of solution, etc., being naturally taken.

Grade of Electrolytic Zinc. With regard to the grade of electrolytic zinc, high purity is easily obtained. This is something that is far more under control than in refining by fractional distillation. Lead ought not to go appreciably into solution at all, while iron, copper, and cadmium—the other common impurities of spelter—are readily precipitated from the solution. The spelter first made at Anaconda was higher in cadmium than is permitted by the standard specifications for 'high-grade.' At that time zinc-dust, more or less impure, was being used as the precipitant for cadmium. Running the clarified solution through a tube-mill filled with zinc balls corrected this, and the grade of spelter was then raised to upward of 99.9%. Brunner, Mond & Co. have been for many years guaranteeing their electrolytic spelter at 99.95% Zn, and there is no reason why the Anaconda spelter should not be made as good as that.

Is electrolytic zinc extraction going to revolutionize the metallurgy of zinc? Unqualifiedly, no. When the zinc industry returns to its normal status, conditions will be in the main as they were before the War and the principles that I have previously stated will continue to obtain, with the difference that some people will have learned the details of the art, will have gone through the period of infantile mistakes in a time when almost any mistake was of no great consequence. By that time some of the concerns possessing exceptionally favorable conditions—Anaconda, if anybody—may be able to continue. Others will not.

However, there are certain new industrial features that cannot yet be clearly estimated and may have a modifying effect upon this forecast. One of these relates to the matter of high-grade zinc. Previous to the War that class of spelter was produced in limited quantity and sold at a premium over common spelter of about 2½c. per pound. Inventors, promoters and others who talked about making such zinc were discouraged from reckoning upon the premium by the dictum that the market would not take any more than the then supply, which was indeed artificially limited, and that it was unsafe to count on anything but the price for common spelter. During the War high-grade spelter has fetched 40c. per pound, and at times the demand for it has been insatiable. This demand has been especially in connection with the manufacture of ammunition and may be expected to cease with the War, but will the advertising that high-grade spelter has had and the wider knowledge of its peculiar properties that has been acquired give it a more extensive use in the peaceful arts and a maintenance of the premium for it, that will be

to the advantage of the electrolytic producer? Or will it become a drug in the market, with entire disappearance of price differential? These are questions that nobody yet knows enough to answer reasonably.

The Bearing of Flotation. Another new and uncertain factor is the bearing of the flotation process of ore concentration upon the metallurgy of zinc. I think that this had a good deal to do with the institution of the Anaconda work. About all metallurgical work is a sequence of steps of concentration and refining, treating the bulk of the ore by a cheap but wasteful process and delivering a concentrated product to a more costly but less wasteful process. Now, most experimenters in the hydrometallurgy and electrometallurgy of zinc heretofore have contemplated the application of a costly process to the run-of-mine ore. The flotation process has enabled ore to be concentrated at relatively small cost with but slight loss. Let it be observed, therefore, that Mr. Laist is applying his costly process not to run-of-mine ore, but to a flotation concentrate in which about 90% of the zinc is concentrated in about one-fourth of the original weight. This is the new and important feature of recent zinc electrolytic work.

We must let our thoughts run a little farther ahead. The treatment of flotation concentrate is one of the present troubles of the zinc smelter, owing to its excessive fineness, which produces difficulties that it would take me too long to describe. Yet the proportion of this class of ore that the zinc smelter is getting is still relatively small. The supply of it is, however, bound to increase, and when it becomes large, the troubles of the zinc smelter will really begin. Now the hydrometallurgist will have the same troubles up to and through the roasting of the ore, but he will be free from those that arise in the distillery. In so far he will have an advantage over his brother pyrometallurgist, but whether it will be a weighty advantage, I do not venture to offer an opinion.

Another thing that may help the hydrometallurgist is improvement in the method of roasting. Twenty-five years ago he used to talk about sulphate roasting. He did not in practice find that idea to work out as well as he expected. While he might be able to render 40 or 50% of the zinc soluble in water, he found there was too much undecomposed sulphide left behind after leaching with sulphuric acid. So then he said he would roast the ore completely, leach all the zinc with sulphuric acid and be done with it. To his surprise he found that much of the zinc had been rendered insoluble by the formation of zinc ferrite if iron were present in the ore, as was almost always the case. The roasting of ferruginous blende in such a way as to convert all of the zinc into sulphate and oxide, avoiding both sulphide and ferrite, which may perhaps be done by correct control of temperature, perhaps by some other control, is an interesting subject for investigation. Mr. Laist has given some attention to this by carefully limiting the temperature of his roasting furnace. However, I think that perhaps the danger of ferrite formation is not very great in the case of his ore. Anyway, I know that it is not in roasting some similar ore of Butte without much regard to the matter of temperature.

Refining and Melting Gold Precipitate

The composition of raw gold precipitate from the Liberty Bell cyanide plant at Telluride, Colorado, varies considerably within short periods, according to A. J. Wernig, in a paper prepared for the September meeting of the A. I. M. E. in Arizona. The variations are as follows:

	%
Gold and silver	25 to 75
Zinc	18 to 30
Lead	0.5 to 52
Copper	0.5 to 20
Silica	1 to 5
Calcium oxide	4 to 8
Sulphur	0.5 to 8

All methods of wet refining, that is, with acid, were discarded after unsatisfactory results. A great deal of experimenting led to the present system of flux refining, which generally embodies the principle of the addition of an oxidizer, and the proper proportion of fluxes to carry off the oxidized impurities as metallic bases in a fluid slag.

A rather wide experience in the melting of precipitate proved that the various impurities are oxidized and driven into the slag in a definite order. Zinc tends to oxidize first, followed by sulphur, lead, and copper. As long as lead is present in the bullion it is almost impossible to drive the copper into the slag. Graphite crucibles are responsible for this.

After removing the precipitate from the press, the computed flux of manganese dioxide, potassium, or sodium nitrate, sodium carbonate or soda-ash, silica, and borax (to suit the particular class of precipitate) is added, and the whole mixed while wet. In a muffle the mixture agglomerates to ⅓ its original bulk, minimizing dusting. The product is excellent for crucible melting, resulting in fast reduction, as much as 1300 oz. bullion per hour. The advantages gained by sintering are many. The completion of practically all chemical reactions in the muffle-furnace prevents any excessive boiling in the crucible, and the crucible may be loaded to the top during the period of melting. The slow application of heat in the muffle-furnace gives ample chance for complete chemical reaction. The flux calculations have been used in 60 melts during 18 months with complete success, there being close approximations to the grade of bullion determined. Slags are melted once a year in a blast-furnace and the only by-products shipped are lead bullion and pig-copper.

During February the San Francisco Mint received 161,269 oz. gold and 76,962 oz. silver. Coinage executed, $20 pieces, was worth $5,860,000.

Uses of Furnace Slag

By Herbert Lang*

THE advance made in the utilization of waste slag from smelting works is small, and, with the exception of the important one dealing with the manufacture of hydraulic cement from certain iron blast-furnaces, no permanent industry has been built upon this metallurgical residue. Although in other directions it is increasingly evident that the trend of thought is toward the conservation of by-products, the proposals for the utilization of slag do not express much that is novel or particularly cogent. This, I presume, is largely because the subject is old and well-worn. Judging by certain suggestions that have been recently made it appears that many persons are unaware of what has been previously accomplished in these directions, and it may prove advantageous to recount briefly what has been done, and what is likely to be done in the future.

The most obvious use of waste-slag, and probably its earliest use, is as road-metal, for which its hardness, brittleness, and density make it especially adapted. When it takes the place of ordinary crushed rock, at no greater cost, the substitution is advantageous. Slag is dustless, it packs well and drains well, making an ideal macadam, but it must be covered with a top-dressing of some more friable substance, the more so as it breaks with sharp edges, trying to horses' feet. A binder is usually intermixed with the fragments; this may be of clay, pitch, or tar. In England a special grout has come into use, prepared by mixing the crushed and heated slag with pitch, before laying. This is a novel proceeding, and is said to be successfully used. Also novel is the proposal to employ broken slag for ballast in lieu of crushed rock, the idea being to discourage pedestrians from trespassing on the track. The sharp edges are supposed to be unpleasant to the feet of the wandering hobo. Copper and lead furnace-slags are better for these purposes than those from iron furnaces, since they are of greater specific gravity, their weight ranging from 3.4 to 3.8, in general, while the corresponding figure for iron slags compares with that of granite, sandstone, and other building stones, which seldom surpass 2.8 or 3.

The manufacture of slag-bricks, building-blocks, and paving-stones from specially tough slags has been practised, and good examples of the construction and use of such may be seen in or about such smelting centres as Butte and Cleveland. An English friend calls my attention to the old dwellings and other slag structures still standing in Cornwall, after more than a hundred years. The manufacture of such blocks is simple, consisting merely in pouring the molten slag into a receptacle of the proper size and form, and allowing it to cool slowly, the slower the better, until it is quite cold. This slow cooling partakes of the nature of annealing, by which the object is rendered much tougher and less liable to breakage from shock. Slag requires this treatment, since without it slag is very sensitive to sudden shocks, although it stands remarkably well the application of slowly applied pressure. The cooling is delayed usually by covering the material with a layer of sand, under which it is allowed to remain for hours or days. Slowly annealed slags of favorable composition acquire almost the hardness and toughness of glass, being equal in compressive strength to the best granite, while surpassing in that regard all other ordinary building-stones. The tougher slags approach glass in their composition, for glass is a true slag, differing of course as respects its chemistry, and some glass-makers have employed a proportion of slag in their 'mix,' adding enough of silicious sand, soda, lime, etc., to bring the mixture to approximately their ordinary formula, and manufacturing therewith the coarser objects of their art, such as bottles, sidewalk lights, etc. It should not be forgotten that silica lends toughness both to glass and to slag, it being the rule that given the same bases the slag (or glass) is the tougher the more silica it contains. Whether the glass-maker of the future will derive some of his materials from slag-heaps is a suggestive question. Slag, of course, is usually quite impure and often not suited for colorless glass; but, on the other hand, the glass-maker's customary materials, such as sand, lime, soda, and lead oxide, are also impure, and it is often difficult for him to obtain them of the proper quality.

Slag in small amounts has been used, also, in the production of the so-called slag wool or mineral wool, so much used for the coating of steam-pipes, for deadeners within walls, and generally where a non-conducting material is in demand. Slag-wool is a curious substance. It is made by blowing a jet of air transversely across and through a falling stream of molten slag as it flows from the spout. Small spheres or spherules of the slag are detached and carried away in the air-current, leaving behind them a fine hair-like thread of the material, which may reach a length of several feet. These threads are frequently formed when tapping, being caused by the escape of the blast. Usually they have a little globule of hardened slag at the far end, and are very attenuated—so fine, in fact, as to be almost invisible. The wool may be collected upon a sieve, which allows the air to pass onward, while intercepting the threads. This interesting and valuable product is more generally made in special fur-

*Metallurgist, Oakland, California.

naces running on a special mixture supposed to be better calculated for the purpose than ordinary furnace products. It is said that the sulphur that accompanies ordinary slags is prejudicial to the manufacture of slag wool, so that it becomes advisable to obtain melting stock devoid of that element. A little slag will make an astounding pile of wool, so that it does not appear likely that its manufacture will ever make serious inroad on the great cinder-heaps that border upon our smelters. A method has been worked out for improving ordinary slag for this manufacture, consisting in re-melting it with a small addition of nitre, by which the sulphur is expelled, rendering it more suitable for this and other purposes. I am not informed as to the practical success of this proceeding.

Referring to the manufacture of hydraulic cement from the high-lime slags of the pig-iron process, the question is often asked: Why cannot copper and lead slags be used for this purpose? The answer is not difficult. In the first place such slags contain no portion of the peculiar basic lime-silicate that has, above all other known substances, the quality of what is called 'hydraulicity,' that is, the tendency to absorb water, to become hydrated, and then harden or 'set.' The relative proportions of the ingredients are unfavorable, the various silicates being of too acid a character. Again, their principal silicate is that of iron, which itself is devoid of cementing properties. In the effort to render such slags of use in cement-making it would be necessary to re-constitute the slag, depriving it of iron and increasing its proportion of lime. This could only be done by re-smelting the slag in an iron-furnace, with considerable additions of limestone, whereby pig-iron would be gotten, thus freeing the material from that metal, while a slag of sufficient basicity would fall, which, if the proportions of other constituents, especially magnesia and alumina were admissible, would constitute a sufficiently good basis for cement manufacture. But considering the relative cheapness of the limestone and clay or slate, which are the usual materials for cement-making, it could hardly be hoped that the residues of such slags would ever be sought for that manufacture. It is only a small part of ordinary iron-furnace slag which is now deemed suitable for it, and we can scarcely expect that any considerable portion of the great slag-heaps that dot the landscape will ever be removed from their present situation for any manufacturing purpose whatever, the more so as many of them lie in comparatively inaccessible positions. However, it is dangerous to prophesy even about slag; and future inventors may have something to say about it.

The ferruginous slags of the copper and lead furnaces are adapted to the manufacture of the so-called metallic paints. They owe their value in this connection to the abundance of iron which they contain. This iron is in the form of silicate of the protoxide, and requires to be converted into the form of free ferric oxide, which, when pulverized finely, gives a bright red powder, suitable for the base of such paints. The process of converting the slag (which is or was carried on at a certain works in New Jersey) consists in grinding the slag, subjecting it to the action of sulphuric acid, by which the silica is set free and the iron converted into ferrous sulphate (copperas, or green vitriol), and then calcining the mass, by which the sulphuric acid is expelled and the iron made to take up an additional quantity of oxygen, forming the sesquioxide, which is the red coloring-matter of the paint. By governing the calcination and the proportion of acid, various shades of color may be produced, having a considerable range. The dry color sells for $20 or $25 per ton in this market, which consumes perhaps 1000 tons yearly. The presence of the silica and such ordinary bases as lime, magnesia, and alumina has no unfavorable effect on the paint, and even adds to its durability, provided they remain insoluble. This manufacture has not been introduced on this side of the continent, but I have made small samples in the laboratory, preparing over 20 different shades of reds and browns, and I believe that the manufacture is perfectly feasible under the conditions here, especially as the various ochres, vermilions, etc., sell at prices much beyond those offered for similar products in the East.

By acting on pulverized copper-slag with dilute sulphuric acid and leaching out the soluble ferrous sulphate from the insoluble residue of silica, etc., good copperas may be made cheaply, at a cost that should allow it to compete with other manufactured brands, which are usually by-products of other processes, or are made, as in this vicinity, by dissolving scrap-iron in sulphuric acid.

Generally speaking, furnace-slags may be divided into two kinds, according to their content of iron. Those made in the pig-iron industry, in which, as a matter of course, the effort is to keep the iron out of the slag (cinder, in that parlance); while in copper and lead smelting, wherein iron is an impurity to be got rid of, its only usefulness consisting in rendering the slags more fusible, the object is to drive it into the slag. Hence this division. Slag made in copper-furnaces, if run through the high iron stack and suitably fluxed with lime, etc., will yield its contained iron in the form of pig, just as crude iron ore will, and the product might be as good as any pig except for possible (and probable) impurities which such slag too frequently contains. This proceeding is carried on to some extent in the case of 'mill-cinder' and 'puddling-slag,' both of which result from the working of pig, and which are very rich in iron, chiefly as the sub-silicate. They form a component of the iron-furnace in some localities, but I have never heard of an instance where they were the sole metallic component, the practice being to feed them along with crude iron ore. The average copper and lead slags contain perhaps 25% iron, reckoned as metallic, and hence could not, in the present state of the industry, be considered as a practicable ore, regardless of what else they might contain. However, with the certain exhaustion of our iron mines, which should take place

within at most a few centuries, the accessible deposits of discarded slag will probably be utilized to some extent. The copper that many slags contain may not, in the light of the new discovery that the presence of this metal to a small extent enables steel to resist corrosion, be found a detriment, while the sulphur that almost all contain in small amounts, may be got rid of perhaps, or otherwise rendered innocuous. Discarded copper slags would average, I think, about 0.5% copper, and both lead and copper slags carry usually one or two per cent of sulphur. Some contain also a proportion of phosphoric acid; but this, in view of the trend of metallurgical invention and practice, may not be viewed as invariably detrimental, although we are well aware of its effects on iron and steel. It is well known that in Germany, where they do many things differently from American practice, a large industry, that of preparing fertilizers from steel-makers' residues, has arisen. By treating phosphoric pig in basic converters a secondary slag is obtained, so rich in phosphoric acid that it is ground and sold to farmers for such a price as to net, it is said, in some instances, a greater profit than the steel which is produced with it. Instead of avoiding phosphoric iron ores the Germans often seek them as most desirable, and our own iron and steel-makers are looking forward to the time when this peculiar manufacture will be established on our continent. Meanwhile the output of phosphate-slag fertilizer (Thomas slag) has reached the annual total, I am informed, of nearly two million tons.

Slag is a great snapper-up of unconsidered trifles. Almost anything that exists in the ores and fuels used in smelting finds its way, if not volatilized and driven off in the smoke, into the slag. Iron goes into it in three, if not in four different forms. First, there is the silicate of the protoxide, which disposes of by far the greatest amount; then there is almost always a little in the form of sulphide, which has a great propensity to dissolve in all slags, especially in basic ones; magnetite has been isolated from many slags; and occasional analysis of exceptional slags shows ferric oxide, united, no doubt, with silica. We may conjecture, too, that one or the other oxide may unite with alumina and perhaps other substances for which it has an affinity, and all these dissolve freely in the general menstruum, provided there is not too much. Copper enters the slag in two forms, mainly as the oxide in combination with silica, but to a much less extent as dissolved sulphide (matte). Occasionally, too, there will be detached particles of metal or matte floating about. Slags which fall from wholly oxidized ores of copper are invariably richer in that metal than those which are produced from ores carrying sulphur (matte-smelting). This is the reason why the old slag-heaps, made from surface ores, are eagerly taken up by the later smelters, who have found sulphide ores, and who invariably fuse them to matte. In this way the old slags are reduced from 3 or 4 or 5% copper to 0.5%, more or less.

Arsenic, antimony, lead, zinc, tin, cobalt, nickel, silver, gold, manganese, molybdenum, titanium, tungsten, uranium, vanadium, and a long list of other elements have been found in greater or less quantity in slags from various processes, but the recital of their occurrences would fill too large a space for discussion now.

It is significant that a chemist (a German, of course) has discovered that radium itself, when contained in ore that is smelted, persists, and is found in the slag. I submit that in view of this fact it would be an interesting research to test the slags of smelters dealing with complex ores here and there, to the end that if their radio-activity were established, further search among the contributory mines might bring to light some radium-bearing minerals. I have in mind one or two slag-dumps, about which I am keeping dark until I can get there with an electroscope and a suitable form of option. But like all other prospective possessors of radium mines, I feel some disquiet at the progress that Uncle Sam, through his Bureau of Mines, is said to be making in reducing the price of radium. Should that price fall to, say, 40,000 times that of gold, I fear the worst. I think, on the whole that our Uncle should retire from such pernicious activities.

Belt-conveyors are used at the Sacramento shaft of the Copper Queen mine to transport the ore to railroad-cars. At the shaft the ore is dumped into a 12-ton bin, the bottom of which is a pan-conveyor that transports the ore to a belt-loader. A V-shaped opening at the bottom of the pan-conveyor allows the fine material to form a bed on the belt for the coarse material; the sides of the V are movable and can be spread to widen the opening when sticky ore is hoisted. Other belts parallel with the railroad tracks load the cars by the help of a mechanical moving tripper. The tripper travels back and forth 36 to 40 times in filling seven cars of a string, serving the purpose also of taking samples which are automatically deposited in an eighth car. The average sample results for a month's run checked the smelter returns to 0.1%. The whole operation is electrically driven, and is controlled from a platform between the loading-belts. The speed of the belts is increased when hoisting is from the upper levels and the belts are stopped when the skips are delayed. A man stationed where he can see all the belts, regulates this. In addition there are two Mexicans to oil and help load, and a mechanic on day-shift to repair parts. The ore is rough, uncrushed, and hard on belts, yet the system gives satisfaction. The total cost of conveying and screening was 2.74c. per ton of ore in 1914. The above notes are from a paper by G. F. G. Sherman at the San Francisco meeting of the A. I. M. E.

Gold produced by its dredges, etc., in Alaska, California, and the Yukon during last year yielded the Yukon Gold Co. $4,209,809 gross, and $2,099,373 operating profit. There was $1,036,081, or 31c. per share, available for dividends, of which 30c. was paid. Preparatory work for the coming season is now under way.

Water Concentration Before Flotation at Anaconda

By Frederick Laist and Albert E. Wiggin

THE concentrator, as remodeled for flotation, consists of eight sections, each of 2000 tons per day capacity, giving a grand total of 15,000 tons per day, allowing for shut-downs, repairs, etc. All sections are alike with the exception of Section 1. In this section, Hancock jigs[1] are used in place of Evans jigs and tube-mills are used in place of Hardinge mills. Fig. 1 shows the flow-sheet of Sections 2 through 8.*

The ore is fed from the bins to a 2 in. round-hole shaking screen, the oversize going to a 12 by 24-in. Blake crusher. The product from this crusher is delivered to a 2-in. round hole trommel, the oversize of which is sent to two 8 by 20-in. Blake crushers. The product from these crushers, together with the undersize from the 2-in. screens, is elevated and passed through 1-in. round-hole trommels. The oversize from this is treated in coarse Harz jigs, making a middling and a concentrate; the undersize is passed through ⅜-in. trommels, the oversize being treated in fine Harz jigs making a concentrate and a middling. All sections are alike up to this point. In Section 1, the undersize from the ⅜-in. trommel is screened on 1½ by 12-mm. trommels, the undersize going to the Anaconda classifiers and the oversize to the Hancock jigs. The treatment of the products from this point is the same in all sections, except that Section 1 uses tube-mills in place of Hardinge mills for grinding, as noted previously. The undersize from the ⅜-in. trommel is screened through 4-mm. trommels, the oversize from these going to the double compound Evans jigs and the undersize going to 1½ by 12-mm. trommels. The undersize from these trommels goes to the Anaconda classifiers, the oversize to double compound Evans jigs. The two sets of Evans jigs make a concentrate which goes to the dewatering bins and a middling which is ground for further treatment.

The concentrate from the coarse Harz jigs is dewatered and conveyed to bins. The middling is screened on a dewatering screen, the undersize together with the hutch product from the coarse Harz jigs going to the Evans jigs. The oversize is passed through rolls, 54 by 24 in., and thence back into the system ahead of the 1-in. round-hole trommels. The concentrate from the fine Harz jigs is sent to the bins. The middling is screened through a dewatering screen, the oversize going to 54 by 24 in. rolls and then back into the system ahead of the 1 in. round hole trommels. The undersize of the dewatering screen together with the hutch discharge of the fine Harz jigs goes to the Evans jigs.

The concentrate from the Evans jigs is dewatered in bins to about 7% moisture, and sent to the smelter. The jig concentrate assays about 15% insoluble and 8% copper. The middling, together with the hutch product is dewatered in tanks and screened through 1½ by 12-mm trommels, the undersize from which goes to the Anaconda classifiers,[2] the oversize through 54 by 24-in. rolls, and back to the 1½ by 12-mm. trommels.

The spigot from the Anaconda classifier is treated on 18 Wilfley tables, fitted with Butchart riffling, making a concentrate and a middling. These tables make a concentrate assaying 25% insoluble and a middling assaying 0.9% copper. The concentrate is sent to the dewatering bins, together with the fine jig concentrate, and the middling is sent to the 10 by 4-ft. Hardinge mills. The overflow from the Anaconda classifiers is sent to the slime thickener division, consisting of 28 by 3-ft. Dorr tanks.[3] The spigot product from these tanks is divided; about one-half is returned to the section and the remainder is sent to the slime plant.

The product from the Hardinge mills (Fig. 2) is treated in six simplex Dorr classifiers—one classifier to each mill—the overflow going to the flotation division and the classifier sand being returned to the mill.

At the time it was first decided to remodel the concentrator, it was not definitely known whether pebbles or steel balls would be used for grinding. To provide for this uncertainty a compromise was effected. The mills were made 10 by 4 ft. and built sufficiently strong for steel balls in case balls were used. Each mill was equipped with a 225-hp. motor directly connected through a flexible coupling. The mill filled with pebbles takes from 95 to 115 hp. to operate. In case steel balls were used it was planned to put in a false wood lining back of the steel lining in the cylindrical part of the mill to reduce the effective diameter of the mill.

This latter plan was finally adopted, and the Hardinge mills will be equipped with the false wood lining, 15 in. thick, in the cylindrical part of the mill, and a Cascade steel lining. With this form of lining, the mill is virtually 7½ by 6 ft. and requires about 225 hp. when loaded with steel balls.

*Abstract from paper to be presented at Arizona meeting (Sept. 1916) of the American Institute of Mining Engineers.

[1]For comparative data on Hancock and Evans jigs, see *Trans.* A. I. M. E., xlvi, p. 212 (1913).

†This flow-sheet appears on page 305 of our issue of Feb. 26, 1916.—EDITOR.

[2]For description of Anaconda classifier, see *Trans.*, A. I. M. E., xlvi, p. 277 (1913).

[3]For description of this thickener plant, see *Trans.* A. I. M. E., xlix, p. 470 (1914).

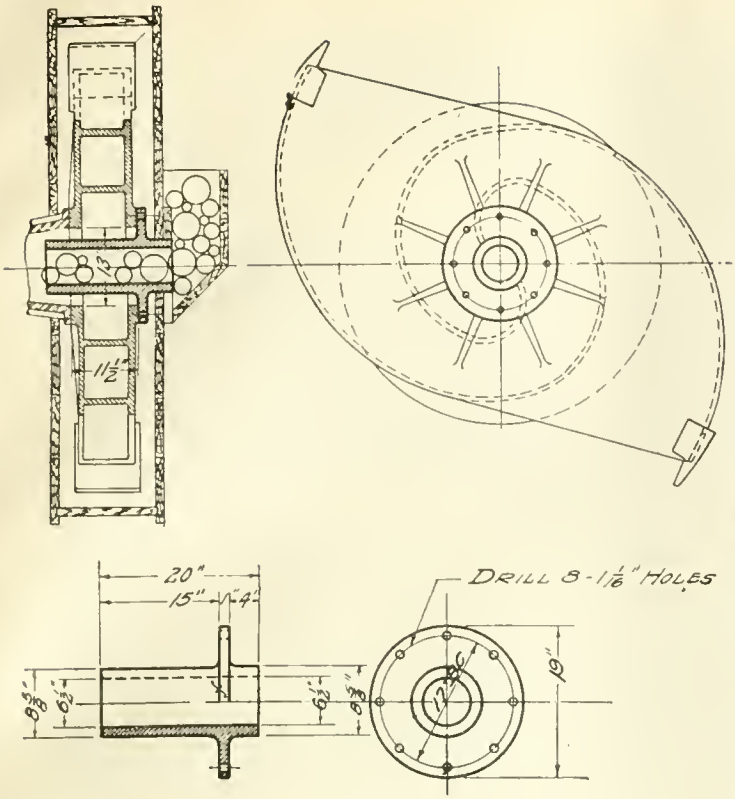

FIG. 2.

The drawing (Fig. 3) gives the details of the lining. This lining was designed by the American Manganese Steel Co.[4] At first the pebbles, and later the balls, were fed to the mills through the feed scoop. This method of introducing the grinding medium into the mill gave considerable trouble, due to the breaking of the feed boxes caused by the jamming of a pebble or ball between the revolving scoop and the feed box. We tried to obviate this difficulty by various changes in the amount of clearance left between the scoop and the box, but without success. In our particular case this trouble was aggravated by the fact that we had to use 7 ft. diam. scoops, in order to lift back into the mill the sand discharged by the Dorr classifier. Finally a method was tried of feeding the pebbles, or balls through a spout passing through the centre of the feed scoop. This device has worked splendidly and all of our mills have since been equipped with it.

[4]A detailed description of these mills, together with grinding data and Dorr classifier data, will be published in a subsequent paper.

Australian Gold Production

The following table compares the gold yield of the Commonwealth for the past two years, according to the official statistics of the various Mines Departments.

	1915 Fine oz.	1914 Fine oz.
Western Australia	1,210,109	1,232,977
Victoria	329,068	413,218
Queensland	249,360	249,468
New South Wales	132,498	124,507
Tasmania	16,000	26,243
South Australia	6,258	6,258
Northern Territory	2,532	2,532
Total	1,945,825	2,055,203

In Victoria the Bendigo district showed a decided decrease. Most of the Tasmanian production is a by-product from copper ore, also in South Australia.

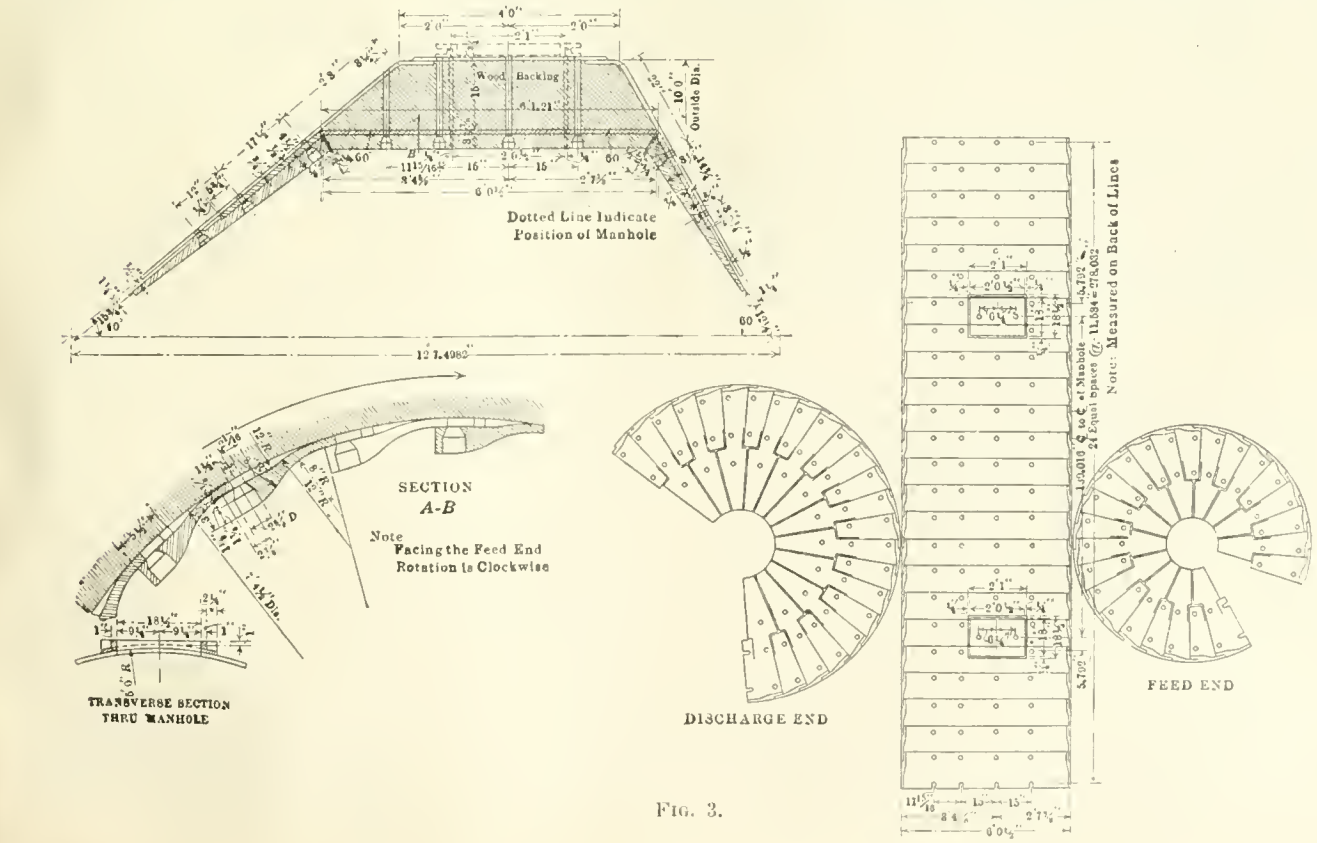

FIG. 3.

CONCENTRATES

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

OPEN-CUT MINING produced over 25% of the ore mined during 1913 in the United States, omitting placers.

VERMILION is the paint made from a particularly pure, nearly translucent, crystalline form of cinnabar, the sulphide of mercury.

HEATING the National copper mill at Mullan, Idaho, costs 24c per ton in winter. This increases the efficiency of both men and machinery.

THE COMPRESSIBILITY of methane (80% of natural gas) is 9% more at 600 lb., and 17% more at 1500 lb., than at 15 lb., atmospheric pressure.

ORE from the Brunswick mine, Grass Valley, California, may be considered free-milling, as during 1915 amalgamation and concentration recovered 90.8% of the gold-content.

SILVER PRODUCTION at the Crown Reserve mine, Cobalt, Ontario, cost 45.01c. per ounce in 1915, an increase of 16.06c., against 54.56c. received for the metal. Abnormal conditions and prices account for this difference.

IT IS COMPUTED that the horse-power of gasoline internal-combustion engines in the United States is more than twice that of all engines in the country driven by steam. The former include 2,225,000 automobiles, 300,000 motor-boats, 45,000 motor-trucks, and 30,000 farm-tractor engines.

THE STEAM-SHOVEL, it is stated, was first used in Michigan in 1887 by Joseph Sellwood, a pioneer of the Lake Superior region, to load iron ore from stockpiles into railroad cars. Later John Jones, of Iron Mountain, Michigan, a widely-known mine-operator and inventor, employed a steam-shovel in the opening of the Biwabik mine on the Mesabi range in Minnesota.

GASOLINE can be obtained in almost inexhaustible supply from the shale of north-western Colorado, north-eastern Utah, and south-western Wyoming, says the U. S. Geological Survey. A ton of some of these shales yields over a barrel of oil by distillation. Natural gas, kerosene, paraffin, and ammonia could be recovered in addition to the gasoline. In Scotland several thousand men ordinarily are employed at the oil-shale industry.

NICKEL is used extensively to toughen steel for bridge construction. The amount of nickel consumed for armor plate, guns, and munitions of war in general, is only a minor proportion of the total nickel production. A good deal of nickel is diverted to the manufacture of minor articles of hardware, cooking utensils, German-silver specialties, and automobile parts. The output of the mines of the Canadian Copper Co. around Sudbury, Ontario, is shipped as matte of 50% nickel, 25% copper, and 25% sulphur to refineries in New Jersey. The matte of the Mond Nickel Co. goes to Clydach, Wales, for refining.

BISMUTH is not a widely used metal. Its brittleness prevents the use of it for anything that should be tough or malleable. It expands on solidifying from the molten condition. While consumed chiefly in medicine, some bismuth is employed in making low-melting cliché alloys, such as in the automatic sprinklers placed as a protection against fire in warehouses and stores, in fuses for electric wiring, and in solders. A little is consumed in bearing metals.

TORBANITE is the principal commercial oil-shale, so named from the Torbane Hill mine, Scotland. It is a brown, fine-grained, schistose shale, having a fawn-colored streak without lustre; sometimes it resembles coal, and it is mined like coal deposits. To reduce, the shale is crushed into blocks the size of bricks, and fed to retorts from hoppers. Ammonia and crude oil are collected in the condensers, after which the crude oil is refined exactly as oil from wells.

OUTPUT of ore on the Rand averages only two-thirds of a ton per man per day. This low figure is due to the extraordinary hardness of the gold-bearing conglomerate and to the native labor employed. The Hollinger gold mine in Ontario, a medium-sized mine, gets about 2 tons per day. At the Treadwell mines in Alaska, where the lode is wide, it is 5½ tons. The British Columbia Copper Co., which aims at breaking ore in a wholesale manner, gets 11 tons per man at one underground mine. The Utah Copper Co., using steam-shovels, has attained 15 tons per man per day.

ALL MINERALS that carry uranium also carry radium, which is now considered a product of the atomic decomposition of uranium. A test for radio-activity is, however, not a conclusive test for radium and uranium, for thorium also has a decomposition product, mesothorium, which closely resembles radium in its behavior, according to the U. S. Geological Survey. Tests for radio-activity will therefore show only whether the specimen contains radium and uranium or mesothorium and thorium. The appearance of the minerals will generally determine which of the elements is present, but in case of doubt the determination requires more elaborate tests, which should be made by an experienced chemist. To test for radio-activity lay the mineral to be tested on a plate holder containing a sensitive photographic plate, and if uranium is present in any considerable quantity the plate will be light-struck within a period ranging from 12 hours to a week, the time depending on the amount of radio-active matter in the specimen. When objects are laid directly upon a sensitized film or plate deceptive effects are obtained by pressure.

Mining in Southern Arizona

By Charles F. Willis

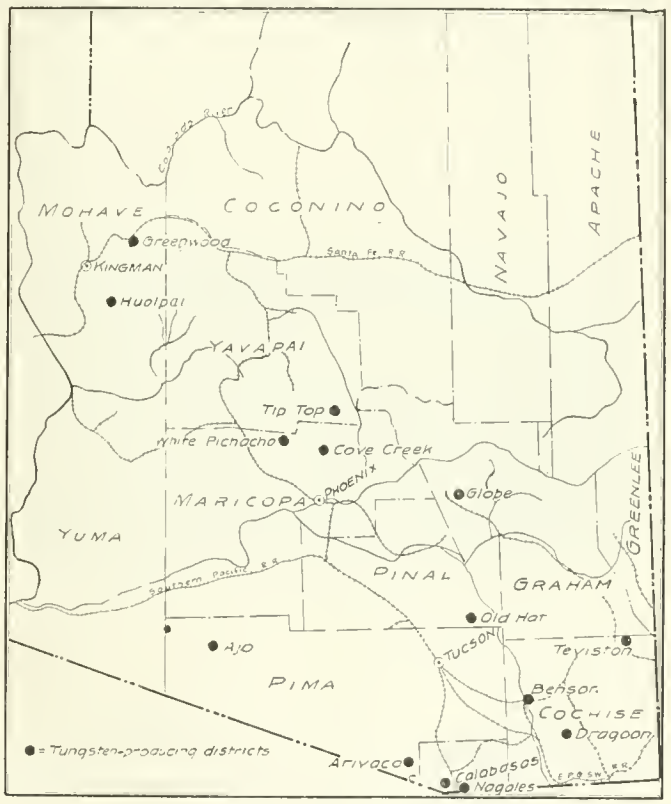
DEVELOPMENTS during the past few months have directed attention to several districts that had been dormant for years. Legends of the wonderful country just north of Mexico, particularly its richness in silver and gems, marked the beginning of mining in southern Arizona. The silver mines of the Patagonia mountains, of Globe, and of Monte Cristo attracted the Spanish explorers, who followed the only feasible route from Mexico, through the valley of the Santa Cruz. They found rich ores that could be taken out on mule-back, but it was not until the '50s that American explorers penetrated the region.

The Ajo mines were located under the laws of the United States by a party of Americans in 1854, and were worked by the Arizona Copper Mining & Trading Co. for half a century, but in a desultory manner. Today the Calumet & Arizona Mining Co. has developed 40,000,000 tons of ore. Under the direction of Dr. L. D. Ricketts, the company has perfected the Greenway leaching process, for the treatment of carbonate ores, with electrolytic precipitation of the copper. A railroad 40 miles long has been built to connect the mines with Gila Bend, so that the old settlement of Ajo, now called Cornelia, has become a thriving city. Work is being rushed on the construction of the reduction plant, and $5,000,000 is being spent in the enterprise as a whole.

The Twin Buttes, another old district, is coming to the front. E. G. Bush and John G. Baxter, with the faith of the true prospector, borrowed $300 with which to do their development work last year. Almost at the grass-roots excellent ore was found, and within three months the Bush-Baxter property was bonded to the American Smelting & Refining Co. for $450,000. Today the Arizonan representative of this company, Julius Krutchnitt Jr., reports that development has been satisfactory, and that 120 tons is being shipped daily to El Paso, this ore running 4 to 4½% copper. Mr. Baxter, however, surmising that there was more than one mine in the district, secured a bond and lease on the Glance, a neglected property belonging to the Twin Buttes Mining & Smelting Co. Again, within three months, he was offered $600,000 for the property, but this time he decided to operate his own bonanza.

At Bisbee, miners are receiving $5.35 and shovelers $5.10 per day. The district is remarkable for the fact that while only nine miles from the Mexican border, none but American labor is employed underground. The Calumet & Arizona Mining Co., which has been operating both its own property and that of the Superior & Pittsburg, has absorbed the S & P. The C & A paid the stockholders of the S & P $21.50 per share, or exchanged one share of C & A for three and a half shares of S & P, giving a bonus of $1 per share for speedy transfer. Although the two companies have been under the same management, the books had been kept separate, involving double clerical work and duplication of taxes, which will now be avoided.

The Arivaca district, including the Guigas mountains and part of the San Luis range, is one of the earliest known mineral localities in southern Arizona. The placers at the foot of these mountains are reported to have financed several Mexican revolutions; they are now



THE TUNGSTEN DISTRICTS OF ARIZONA.

largely owned and operated by the New Venture Placer Mining Co. The gold in these deposits came undoubtedly from the Guigas (meaning 'pebbles') mountains. At the present time this district is more remarkable for its tungsten. Two companies, the National Tungsten Co. and the American Tungsten Co., are employing about 500 men, and maintaining regular shipments of tungsten ore.

The Babaquivari district is in a range of the same name on the west side of the Arivaca valley. The Cababi and Comobabi districts are in the central part of Pima county. This region was the scene of much historic mining and prospecting. Notable in the history of the Southwest is the Picacho mine, whose rich silver ores were sent

far into Mexico for treatment. The network of old shafts, inclines, and drifts has made later development difficult, although the deeper workings have revealed the existence of orebodies that it is believed will rival those of the higher levels.

The Old Hat district has become the scene of renewed activity. The Copper Queen Consolidated has entered the district and has done systematic prospecting. The Daily Arizona Mining Co. has been developing a property on the northern side of the Catalina mountains with favorable results. The Stratton Copper Co. has a good quantity of what, at the present price of copper, is high grade copper ore. This company has built a remarkable road of approximately 18 miles for motor truck haulage. The Old Hat district has also produced some scheelite and hübnerite.

The notable event of the month was the purchase of the properties of the Imperial Copper Co., at Silver Bell, by the American Smelting & Refining Co., and the leasing of the Sasco smelter, with the restoration of the Arizona Southern railroad. The Imperial properties cover about 1000 acres in the Silver Bell mountains, a small independent range, having a granitic base, with limestone and quartzite capping, the latter much eroded and entirely gone at points. There has been faulting and shearing, the orebodies occurring as irregular contact-lenses, having a north-westerly strike with axes parallel with fault-fissures. The granite porphyry in the vicinity of the lenses is strongly mineralized with copper sulphides. The zone of oxidation is comparatively shallow, no deeper than 150 ft. in the principal workings. The oxidized ores that furnished the bulk of past production are mainly cuprite, malachite, and azurite, while the sulphide ores are chiefly chalcopyrite and some bornite. The mines also show some cupriferous silver-lead ore. This property, owned formerly by the Development Company of America, has suffered from the long litigation of the parent company; it is reported to have produced $8,000,000, but a year ago was sold at bankruptcy sale. Immediately following the sale, the American Smelting & Refining Co. secured permission to churn-drill the property in order to check the assay-plans of the former management. It is evident that the results were satisfactory, for the new owners have taken possession. This is the largest developed mine in the vicinity of Tucson, being but 35 miles south-west. The operation of this property in connection with that of the Bush-Baxter mine, recently acquired by the same company, means much to southern Arizona. The leasing of the Sasco smelter from the Arizona Smelting & Refining Co. for $2000 per month means the production of 900 tons of ore daily, and will undoubtedly open a local market for custom ores.

The Patagonia district in Santa Cruz county is a famous producer of copper, gold, and silver. The Old Mowry is a lead mine that was shut-down during the Civil War by the Federal authorities, being suspected of supplying lead for Confederate bullets. The World's Fair mine is now being operated profitably. The Trench, which was operated in the '50s, has been bonded to W. A. Clark of the United Verde and is being developed systematically. The Hardshell and Flux mines, discovered in 1879, were purchased in 1880 by the present owner, R. R. Richardson. Considerable ore has been shipped, and now the mine is being deepened.

It has just been announced that the Empire Zinc Co. of New Jersey will operate the San Xavier zinc-carbonate mine, which they have owned for some time. For several weeks the engineers have been getting the property in readiness for operation and making a preparatory survey either for a railroad or aerial tram of eight miles to the Nogales Branch of the Southern Pacific railroad.

Although, as regards mineral production, Pima county has been behind Cochise, Greenlee, Yavapai, Gila, Mohave, and Pinal counties, the commencement of large-scale operations by such companies as the Copper Queen Consolidated, the American Smelting & Refining, the Empire Zinc, and the Calumet & Arizona promises a new era of successful development.

Accidents at Anaconda

The Bureau of Safety of the Anaconda Copper Mining Co. has compiled the following data on accidents at its properties during 1915:

	Per cent of fatal and serious accidents.	Per cent of all accidents, including slight.
Falling ground and rocks.....	12.8	32.3
Handling timber, tools, pipe, etc.	16.4	17.9
Ore-cars and trains.....	14.8	8.7
Falling timber, tools, etc.....	4.1	4.2
Men falling through floors.....	6.8	3.1

The following tabulation gives the accident rates per 10,000 shifts for each quarter of the year 1915. The accidents considered include all on surface and underground of the classes given that occurred in the metal mining department:

	Fatal.	Serious.	Per cent reduction by comparison with 1st quarter.
First quarter	0.09	1.83	...
Second quarter	0.17	1.52	17.0
Third quarter	0.09	1.03	43.9
Fourth quarter	0.05	0.89	51.4
Average for the year, all mines	0.10	1.32	27.9
Anaconda group	0.10	1.42	25.3
B. & M. group.....	0.10	1.21	32.4
Southern Cross mine....	...	0.57	...

Over 50% of the injuries caused by falling ground was due to carelessness of the men themselves.

New Mexico has an area of 122,580 square miles, which is more than twice that of Georgia. Its population, 400,000, is more than that of Arizona, being equal to Utah or Idaho. New Mexico's output of copper in 1915 was greater than that of Nevada. The State's production of minerals last year was $22,000,000.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

LEADVILLE, COLORADO

INTERESTING NOTES ON LABOR TROUBLE AT THE LOCAL SMELTER.

On Friday, February 25, five hundred smelter-men employed at the Arkansas Valley plant of the A. S. & R. Co. went on strike for higher wages, and an adjustment of the existing working conditions. The following Sunday, E. E. McLaughlin and A. J. Warren, chairman and secretary of the Colorado Industrial Relations Commission, arrived from Denver and took charge of the situation. They stated that the smelter-men had violated the new act that went into force last August, in connection with the workmen's compensation law, and that they were subject to the penalities provided in the law.

The clauses of the law covering the case are quoted below: "Employers and employees shall give at least 30 days' notice of an intended change affecting conditions of employment with respect to wages or hours; and, in every case where a dispute has been made the subject of an investigation, hearing, or arbitration by the Commission, or the board, until the dispute has been finally dealt with by the Commission, or board, neither of the parties nor the employees affected, shall alter the conditions of employment with respect to wages or hours, or on account of the dispute, do, or be concerned in doing, directly or indirectly, anything in the nature of a lockout or strike, or a suspension or discontinuance of work or employment; but the relationship of the employer and employee shall continue uninterrupted by the dispute, or anything arising out of the dispute; but if either party uses this or any other provision of this Act for the purpose of unjustly maintaining a given condition of affairs through delay, such party shall be guilty of a misdemeanor and, upon conviction thereof, shall be punished by a fine of not more than one hundred dollars."

"Any employee, who goes on strike contrary to the provisions of this act shall be guilty of a misdemeanor and, upon conviction thereof, shall be punished by a fine of not less than ten dollars ($10) nor more than fifty dollars ($50) for each day or part of a day that such employee is on strike."

Mr. McLaughlin contended that each and every smelter-man on strike was liable to the rulings of the above law, and that they should be dealt with accordingly. However, the fact that the men were all foreigners, the greater number being Austrians, and that they were not familiar with the law, was taken into consideration. The other members of the commission, Frank P. Lannon and E. L. Williams, together with Attorney-General Farrar, were called to the scene, and it was decided to give the men a chance to return to work before taking legal steps against them.

The Commission held several conferences with the men, and fully instructed them through an interpreter as to the readings of the law and their violation of it. The strikers then contended that they did not strike, but stated that they had simply quit work because they did not wish to labor under the conditions at the plant. A great number of them drew their time-checks and thereby put themselves within the law.

The Commission then adopted a policy urging the men to make known their grievances and to return to work so that an investigation could be legally taken up.

The men stated that they did not want to go to work until they were given an increase of 50c. per day, and the system of hiring and firing had been adjusted. They said that under the present arrangement they were subject to graft on the part of the foremen in the smelter and were under the control of a company store, which, although not in connection with the company, was just as binding. Frank Zaitz, president of the Hart-Zaitz Mercantile Co., the store in question, is accused by the men of forcing them to trade with him or lose their jobs. For several years he has acted as a sort of 'padrone' to the smelter-men, and at the same time it is alleged that he has had an agreement with the company for furnishing labor. This gave him an almost absolute control over the men. He could get them work and if they did not do as he wished he could have them discharged or laid-off, according to the stories of a number of the strikers. It is a known fact that he draws time-checks for the greater number of the men at the smelter through assignments of wages, which it is stated he demands from the men before giving them work. Some of these assignments call for wages over a year in advance. In many cases it is said that the men do not owe him a cent, but that in order to keep their jobs they must allow him to draw their checks

A SMELTER AT LEADVILLE.

and trade at his store. He settles up their accounts every month, and gives the men what is left. He is accused of charging them higher prices for his goods than other merchants and of generally "holding them up" whenever an opportunity presented itself.

Upon getting a statement of these demands from the smelter-men, the Commission began an energetic campaign to persuade the men to return to work, promising that an immediate investigation of their conditions would be started as soon as the strikers obeyed the rulings of the industrial act, namely, to give 30 days' notice before walking out.

Several days of activity among the members of the Commission and repeated conferences with the men proved unavailing, as it appeared that the situation was to develop into violent outbreaks. Many of the men wanted to heed the instructions of the Commission, but a number of agitators stood firm on their demands and refused to go back to work until promised the wage increase. These men it seemed had control, and were threatening any of the others who wished to go to work. Two men who did go back were waylaid and beaten, and as a result others were afraid to risk it. Fritz von Fischer-Ankern, vice-consul of the Austrian legation at Denver, was called to the scene and talked to the men. He tried to make them see the position of the Commission and understand that their conditions would be greatly improved if they would just

revert to work and thereby allow an investigation. Still the men refused to be moved from their stand, and Governor Carey was advised of the situation. He immediately replied that if the men did not go back to work they should be treated as violators of the law, and if Lake county did not have sufficient power to enforce the law, State aid would be sent at once.

The prospect of having the militia intervene aroused a number of local men to action in a final effort to have the matter settled at least temporarily, without the necessity of calling in the troops. A few influential Austrians took a hand in the affair, and gradually persuaded the greater number of the men to return to work for a month, or until such time as the Commission could complete an investigation of their grievances and make its recommendations to the company. By Sunday, March 5, nearly all of the men had returned.

The smelter, which had been reduced to one furnace, quickly resumed its normal activity and early the following week had five again in blast. No damage was done to the plant.

It is the general opinion here that the smelter-men have a number of just grievances which should be investigated by the Commission. The matter of wages will be looked into and comparisons made with other plants in the State, and if the Commission finds that an increase should be made it will be urged upon the company to do so. The system of employment and the company-store matter will be adjusted satisfactorily, it is thought, and the men will secure the privilege to do as they see fit in the matter of trading. There is, however, much to be said in favor of Frank Zaitz and his dealing with the men in his connection with the Hart-Zaitz Mercantile Co. These smelter-men upon arriving here know practically no one, and it is doubtful if they could secure credit from other firms as they are able to from the Zaitz concern. He keeps them supplied with the necessaries of life, in many cases when they are not at work, and relies on his ability to get the men a job and to then draw their checks for payment. Whether this privilege is being abused is a matter for the Commission to decide. The Commission is now busy on the investigation.

PLATTEVILLE, WISCONSIN

NOTES ON IMPORTANT EVENTS IN THE ZINC REGION.

From every point of view February, usually a dull month in the zinc-mining districts of Wisconsin, this year proved a glowing exception. Intermittent periods of severe winter weather, followed by sudden thaws, interfered with milling and left very bad roads. Strikes, especially among shovelers, nearly all of whom demanded increased pay or uniform can rates, threatened for a time to disrupt the entire field. Operators at first refused to meet the demands of the men, and enforced suspensions of operation were made until new gangs of men could be recruited. In some of the districts the disaffection spread to entire working-forces, but the absolute scarcity of men of all classes and continued high prices for zinc ore inspired operators to concede the demands, and the close of the month found the field again harmoniously employed. For the first time in the field drilling-rigs with squads to man them went at a premium, and scores of lessees went begging for outfits, unable to secure any service at all. In the Benton and New Diggings districts every available foot of ground has been secured for mining and prospecting purposes, either by lease or purchase, and many new concerns have made initial investments in drilling-machines in order to get started. Scores of miners are living in tents, while barns and attics provide shelter for many unable to secure houses. Building booms flourished at all of the southern mining centres, including hastily constructed shacks to important municipal improvements. The elaborate drilling program resulted in numerous rich discoveries of both zinc and lead ore in every part of the field. Sales of mining properties were numerous, especially where it was shown that ore could be readily secured by providing the necessary equipment, and capital flowed into the field from many parts. Several new modern mining equipments were started, and millwrights crowded with work have contracts to fill that will take a year to complete. The Inter-State Light & Power Co. of Galena, Illinois, for a year or more past has regarded the abnormal demand for current as a 'war load' and refused to provide increased capacity. Numerous break-downs under the power available, just as prices for ore reached top levels, engendered a feeling among operators that put them in a most belligerent frame of mind, and threats of damage-suits for current being furnished under contract were freely made, with the result that capacity will be doubled. A new battery of boilers of 3500 hp., and a 3000-kw. generator are being installed. Two new separating-plants were started; one for the New Jersey Zinc Co. at Mineral Point, and the other for the Galena Refinery Co. at Galena. The National separating plant at Cuba, treating 4000 tons of crude ore per month installed four additional Dings electro-static machines, raising the capacity to 5200 tons.

Zinc-blende prices were exceptionally good all the month. At the beginning of the month a base range slightly in advance of $100 per ton was paid, rising to $115 and $125 at the middle, falling away to $95 to $110. Miners of zinc carbonate in the northern district had a surprise, one sale being at $60 per ton.

FLAT RIVER, MISSOURI

FLOURISHING CONDITIONS IN THE LEAD REGION.—NEW MILL.—FINE-GRINDING, CONCENTRATION, AND SLIME FLOTATION.

The rising price of lead has greatly stimulated mining operations in this district. During the last year the output of lead has been at a maximum, and has been limited only by the milling capacity of the different companies. Quite a little optioning has been done this winter, and drill-prospecting is being hurried. Most of the known mineral land in the district is owned by five large operating companies, namely, the St. Joseph Lead Co., the Doe Run Lead Co., a subsidiary, Federal Lead Co., St. Louis Smelting & Refining Co., and the Desloge Lead Co. About three or four years ago another company, the Baker Lead Co., controlled by Boston capital, entered the field. This company has operated a shaft near Leadwood, and is now sinking a new shaft south of Elvins. The ore is milled by the St. Louis Smelting & Refining Company.

The Federal Lead Co. broke ground on the first of March for a new 2000-ton mill, just west of Elvins. The company expects to finish it in about four months, in order to benefit by the high price of lead. The mill will be practically a duplicate of the present one in its equipment.

Finer grinding is being considered in this district, and this summer will probably show developments along this line. The Doe Run company has ordered a Marcy ball-mill, the Desloge company a Hardinge ball-mill, and the Federal and St. Louis companies Marathon mills. The present intention is to regrind the Hancock jig-middling, and treat it with tables and flotation.

Table practice is also being changed in some of the mills. The St. Joseph and the Doe Run companies have adopted the Butchart riffle system on their Wilfley tables. This system has enabled them to handle much large quantities on the tables, thus increasing the capacities of the mills.

The mill-slime in the district is being treated by flotation, and metal recovered which in former years was lost. The Doe Run company has just added another flotation plant to its mill at Rivermines. This gives a capacity to treat approximately 600 tons of slime per day.

Labor conditions in the district are good at present. All the companies have raised wages by giving the men a bonus as the price of lead has advanced. Last June a bonus of 10% was added, and another of 10% on February 15. This makes wages higher than ever before. The men seem quite satisfied, and the output per man is at a maximum.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

In accordance with plans approved by the Secretary of the Interior, the investigation of the mineral resources of Alaska by the Geological Survey will be continued this year by 12 parties. Congress has recognized the necessity of preparing in advance for the survey of this difficult field by including the appropriation for its continuation in the urgent deficiency act, which was approved on February 28. This prompt action makes it possible to plan the work in advance of the opening of the field season, and to carry out the plans efficiently and economically.

The work to be done this year includes a detailed survey of the region tributary to Juneau, which is the most important quartz area in Alaska. A continuation of the study of the mineral resources of the Ketchikan district, where there are important gold and copper mines, is also planned. The investigation of the water-powers of south-eastern Alaska will also be continued. Only one party will be employed in the Copper River region. Two parties will work in Prince William sound. Four parties will make surveys in the region directly or indirectly tributary to the Government railroad under construction. One of them will study the new Tolovana placer district, and also make some supplementary investigation of the Fairbanks lode district. The geologist of this party will later visit the Nome district. A detailed geologic survey will be made of the western part of the Nenana coalfield, which is adjacent to the route of the Government railroad. Two other parties will be employed in carrying reconnaissance surveys westward from the railroad route to the Kantishna placer and lode district. It is also proposed to make surveys of the lower Yukon, including the Marshall placer district.

ARIZONA

In Bulletin No. 11 of the State Bureau of Mines, A. C. Rubel discusses tungsten generally, and its occurrence in Arizona. An accompanying map shows the areas in which the mineral is found. Bulletin No. 12, by P. E. Joseph, deals with quicksilver, which is mined in the Sunflower district of Maricopa, and Plomosa district of Yuma county. A list of tungsten-ore buyers is given by the Bureau. Bulletin No. 14, by Frank L. Culin, Jr., deals with magnesite. Bulletin No .16, by the same author, covers mica. There are several deposits of this mineral in Arizona, but none have been much developed. The occurrences are in the north side of the Grand Canyon, Coconino county; in the White Horse Tank mountains, south-west of Phoenix, Maricopa county; Mohawk mountains of Yuma county; and the Santa Catalina mountains, Pima county.

The Bureau has issued a press letter regarding the number of samples sent to it for determination. Many of these are poorly packed and labeled. Questions regarding the minerals present in rocks are permissible, but assaying is not done free.

Cochise County

The following additions and improvements are to be made to the Calumet & Arizona equipment: a 200-ton sulphuric-acid plant, 2 reverberatory and 12 roasting-furnaces, another blowing-engine, enlargement of the sampling-plant and storage-bins, electric transmission-line, and fire-proof storehouse. The design is in charge of A. G. McGregor for Repath and McGregor.

Greenlee County

On March 9 a union employee was discharged by the Shannon Copper Co. for impertinent interference, whereupon the mine, mill, and smelter were rendered idle by a general strike, pending a conference with the manager, J. W. Bennie. The American employees remained at work.

The strike has been settled after a week's stop.

Mohave County

An apex-suit is reported as probable between the Tom Reed and Big Jim companies at Oatman, the former being the complainant.

A new treatment company, under the name of the Lorezona Ore Purchasing & Reduction Works, has been formed and proposes to handle the concentrates and smelting ores from the Kingman-Oatman-Chloride districts. The object of the company is to afford a market for the ores developed by small operators who have not sufficient tonnage opened to warrant the construction of mills. This will undoubtedly add much impetus to the development of mines in that part of Arizona.

After having installed a 25-hp. hoist and a 500-cu. ft. air-compressor, the Times company, four miles from Oatman, has resumed sinking and development. The water-supply is sufficient. Prospects are most encouraging.

The Oatman Pioneer mine, 1¼ miles west of the United Eastern and Tom Reed, has been acquired by the Keith's of Boston. Valuable ore-shoots have been found in this area. The shaft is 400 ft. deep. In the Arizona-Tom Reed, Apex Pioneer, and others farther west development is giving fine results. Well-known engineers reported favorably on the area.

Yavapai County

More discoveries of tungsten ore are reported from the Tule Creek area. The Tule Creek Tungsten Co. contemplates erecting a mill for itself and custom ore.

CALIFORNIA

Amador County

(Special Correspondence.)—Work at the Amador Star mine is progressing rapidly generally.

The Oneta gravel mine, near Charleston, recently uncovered a good deposit. This property is owned by the Oneta brothers.

At the Treasure mine, north of Amador City a contract for building a new mill has been let. Grading is well under way, and mill construction will start in the near future. A large sum of money has been spent on this property in sinking the shaft and prospecting. So much good ore has been opened on the lower level that the company is justified in erecting a mill. J. H. Bell is manager.

Dividend No. 116 has just been paid by the Bunker Hill company at Amador City. During the past 10 years this company has not missed a single monthly dividend. E. Hampton is superintendent.

Amador City, March 11.

Following is the preliminary report of the Plymouth Consolidated for February:

Ore milled, tons	11,000
Value of output	$58,393
Working expense	30,420
Development	5,794
Surplus	$22,179
Other capital expended	121

During 1915 the South Eureka Mining Co.'s income was $582,762, and dividends paid $125,354.

Calaveras County

(Special Correspondence.)—The Utica Mining Co. is now extracting and milling about 6000 tons of ore per month at the Gold Cliff mine. Twenty stamps are dropping at the Utica cross-shaft) mill, on ore from development in that mine. A comprehensive prospecting and development scheme has been followed in the past two years, which will be understood when a few facts relating to the relative positions of veins in the two mines are described. The Gold Cliff and Utica veins are about 3000 ft. apart on the surface, converging somewhat in their southern trend, and also as depth is attained. Development tends to show that within a short distance from the bottom of the present workings, these two veins will come together as a large one. The pitch of the Utica vein, at or near the surface, is 60° to the east, while at the 2400-ft. level it has a pitch of 70°. The Gold Cliff, on the other hand, at or near the surface has a pitch of 55° to the east, and at the 1900-ft. level has changed to 40°. The present lower workings of the Utica show the vein at that point to be about vertical, with a probability that at the depth of 2700 ft. the two veins will junction, when, it is anticipated the value will be greater, and a larger body of ore than ever will be found. Fred J. Martin is superintendent.

Angels Camp, March 1.

Eldorado County

At the Georgia Slide mine, near Georgetown, 60 men are employed, with a pay-roll of over $6000 per month. A mile of pipe has been laid. 10-stamp mill is in course of erection, and driving an adit is under way in charge of J. C. Ingersoll.

Glenn County

Early in April the California Chrome Mining Co. will commence shipping chrome ore to Fruto from its mine 19 miles distant. The first contract will be 5000 tons.

Nevada County

The Buckeye quartz and Cold Springs gravel properties, and other claims, totaling 1000 acres, a few miles north-east of Nevada City, have changed hands. F. S. Burr and S. L. Bright of San Francisco represent the new owners.

Plumas County

Diamond-drilling the ore-shoot in the Walker mine gives an average of 7.28% copper, 2.7 oz. silver, and $1.11 gold per ton over a length of 200 ft. Machinery for the tramway and 100-ton flotation-plant is arriving.

San Bernardino County

A rush has set in for a gold district 25 miles north of Barstow. A. A. Turner of the Goldstone mine has brought in rich ore to Barstow.

San Luis Obispo County

Eastern capital last week bought the Oceanic quicksilver mine for $400,000. San Francisco people were interested in the property. In 1914 this county produced 1336 flasks of metal, mostly from the Oceanic, which is equipped with a 50-ton Scott furnace, 2 D-retorts for soot, and a small mill.

Siskiyou County

On account of the heavy snow-fall in this county there will be an abundance of water for mining this season.

Engineers are examining the Blue Ledge copper mine at Copper. At one time this property employed over 200 men.

Trinity County

(Special Correspondence.)—Three miles north-west of Carrville, on Coffee creek, at the mouth of Morrison gulch, the Trinity Development Co. is to install a large dredge now being constructed in Ohio.

The old Golden Jubilee mine, six miles north of Carrville, is being re-opened by the California Extraction Co. Fifteen men are employed, the number to be increased when snow disappears. A compressor and two water-Leyner drills are used.

Carrville, March 4.

Tuolumne County

Under the leasing system last year the Jumper mine at Stent yielded gold worth $100,000. The royalty is 25%. Ore is treated at the company's mill.

COLORADO

Clear Creek County

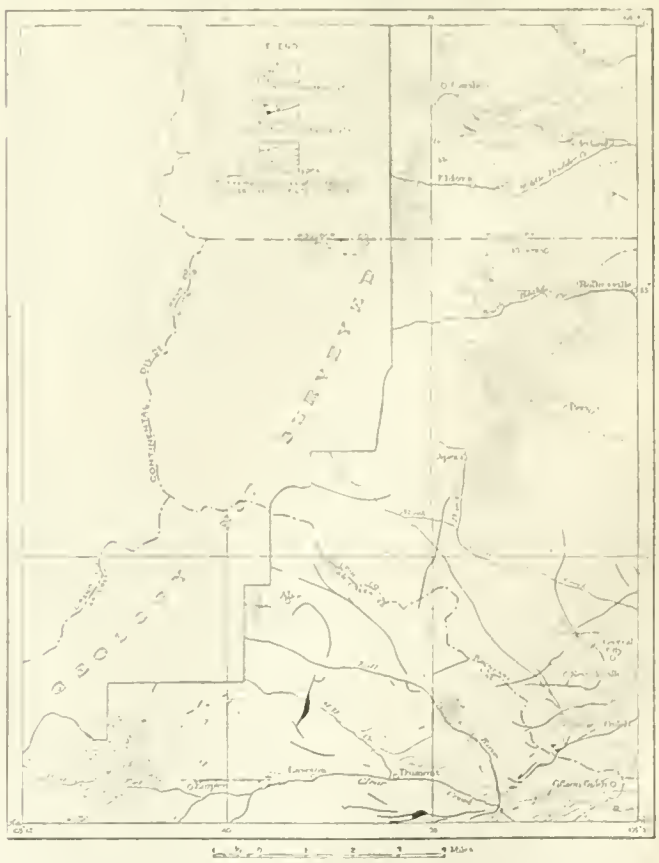
(Special Correspondence.)—Since the Argo mill was provided with flotation apparatus 92% recovery of the metallic content of the ores treated is reported by the manager, J. A. Pearce. The plant is being operated three 8-hour shifts, dealing with 150 tons per day. Most of the supply comes from the Gunnell mine.

Idaho Springs, March 13.

Gilpin County

A shipment of 112 tons of radium ore, worth approximately $85,000, was received last week at the Colorado School of Mines at Golden. It is the largest shipment ever made in Colorado. The ore came from the Colorado-Gilpin Gold & Radium Mining Co., and is destined for the U. S. Bureau of Mines at Denver, after it has been concentrated at the plant of the School. The shipment is estimated to contain 715 milligrams of radium.

Bulletin 620-M of the U. S. Geological Survey, 'Preliminary Report on the Economic Geology of Gilpin County, Colorado,'



GEOLOGIC FEATURES OF PART OF GILPIN COUNTY.

by Edson S. Bastin and James M. Hill, has been published. With plans it covers 29 pages. Charles W. Henderson assisted in some of the field-work. In the PRESS of September 18, 1915, an abstract of this paper was given with a map, as the preliminary notes had been published in *Economic Geology*.

Teller County (Cripple Creek)

The Vindicator company has secured an option on a large brick building and ground at Goldfield, owned by the Arkansas Valley Light & Power Co., presumably for a flotation plant to treat the former's low-grade ore.

IDAHO

Lemhi County

During 1915 the Gilmore Mining Co. produced 10,173 tons of gold-silver ore, yielding $114,539 net. The Latest Out, adjoining, produced 31,000 tons of 30% lead ore, and the Gilmore company is exploring to cut the downward extension of this vein.

Shoshone County (Coeur d'Alene)

On March 23 the Success company paid 3c. per share, equal to $45,000.

On March 11 about 4000 men working at mines tributary to Wallace received their pay, including the 50c. a day bonus for high lead prices. The lowest average wage was $116 for February.

The Black Horse mine and mill are to resume operations at an early date by the Murray Hill Mining Co., organized by C. E. Mallette of Spokane. Zinc concentrate will be sold to the U. S. S. & R. company.

In the Pine Creek district a 13-ft. lode has been opened, 9 ft. assaying from 30 to 50% zinc, the remainder being of good grade for a mill, in the Little Pittsburg mine. It is owned by Gus Smith of Spokane, but is under option to the Colonial Mining Co. of Wallace.——In the same district 8 ft. of 42% zinc ore has been cut in the Constitution mine. Thirty men are employed. The company has decided that a 100 or 150-ton mill will be erected as soon as advisable.——There are 30 four-horse teams hauling ore from the Little Pittsburg, Highland Surprise, and Constitution mines. At the Pine Creek siding the railroad is erecting ore-bins. It seems that the district will have a line built through it this year, as somebody has secured right-of-way for a road from the mouth of the creek to the Constitution, and for three miles up the west fork. The C. M. & St. P. railroad is thought to be interested.

It is reported that Pine Creek antimony producers will make no more shipments until they receive better prices for their product. They claim that the smelters are making too much profit by paying low prices.

As has been mentioned before, the Anaconda company has purchased the Douglas lead-zinc mine for $360,000. A mill is to be erected, concentrate going to Montana for reduction to metal.

On March 20 the Hecla Mining Co. pays 10c. per share, or $100,000, making $300,000 for 1915, and $4,055,000 to date.

MICHIGAN

The Copper Country

It is reported that the Calumet & Hecla company has offered $59 per share and some stock arrangement for the Tamarack property.

On March 12 the four-stamp mill of the Trimountain company was destroyed by fire. The loss was $200,000. The plant will be re-built.

MISSOURI

Jasper County

Zinc-ore prices were lower at Joplin last week, a decline of $15 per ton. Producers do not feel that they are getting enough for their ore, and there is talk of a curtailment. Smelter representatives, on the other hand, maintain that the metal situation is so uncertain that they are not justified in paying higher. Evidently there is a wide variation of opinion between buyers and producers as to what constitutes an equitable price for ore under existing conditions. In this respect it is interesting to recall that the smelters all along have set forth the so-called uncertainty of the spelter market as being the chief reason for their refusing to advance ore prices higher than they have been; yet the reports of the various smelting companies show that most of them have reaped much larger profits, proportionately, than have the mine operators. A fact that is not to be overlooked, however, and one that the smelters advance is that prior to the sharp advance in zinc the smelters, like the mine operators of that period, were running on either limited margins of profit, or were operating at an actual loss, according to the *Joplin News Herald*. The output of the Missouri-Kansas-Oklahoma region was 7442 tons blende, 292 tons calamine, and 1146 tons lead, averaging $90, $72, and $89 per ton respectively. The total value was $809,411, and for 10 weeks, $8,259,652.

On a lease at Prosperity the Franklin Mining Co. is to erect a 400-ton mill, driven by two 250-hp. Bessemer engines. The mine contains a large quantity of 4% blende ore.

A 1000-ton mill is to be erected by the Coahuila Lead & Zinc Co. at Duenweg. A 250-hp. Corliss steam-engine and Sullivan straight-line 1200-cu. ft. compressor are part of the machinery.

MONTANA

Fergus County

During February the Barnes-King properties produced 6049 tons of ore yielding $43,800. Development in the Shannon ground is good.

Granite County

A recent addition to the geologic map of the United States, just published by the Geological Survey, is the folio covering what is known as the Philipsburg quadrangle, in south-western Montana. The area covered is 827 square miles, which includes several important metalliferous mining districts, among them the Flint Creek (Philipsburg) and Cable (Southern Cross) districts. The folio is the result of geologic investigations by W. H. Emmons and F. C. Calkins. The Flint Creek district is one of the most productive silver-mining regions on the continent. During most of the period from 1888 to 1893 it led all other districts in the United States in output of silver. In 1867, soon after the first discoveries, the Hope mill, which is still standing, was built to reduce the silver ores. The town of Philipsburg grew up about this mill and has maintained itself ever since as the principal settlement of the region. Much of the ore found in the Hope mine was so rich that it could be readily melted down to bullion in an ordinary blacksmith's forge, and the Granite-Bimetallic vein contained what is probably the largest body of high-grade ruby silver ore ever discovered. It has yielded more than 1000 tons of metallic silver that had a value of about $32,000,000. Extensive bodies of ore still remain in this district, but since the decline in the value of silver in 1893 they have been worked to a moderate extent only. Rather curiously, the Cable, and adjoining districts, although only 10 miles from Philipsburg, produce gold almost exclusively. They are also among the first discoveries in this region and are more active now that at any former period.

Lewis and Clark County

The Helena Mining Bureau is to hold regular monthly meetings to keep up interest in the mining industry. Through this institution has resulted development of the Head mine; the Eastern Belle, the final payment upon which has just been made by Huffaker and Hill; the Conrad-Perry property; the Allen group of claims, and others in the Scratch Gravel district, as well as at Unionville, Marysville, Alhambra and elsewhere in the Helena district. New properties are being listed with the Bureau which may be purchased or otherwise examined. A lot of interesting news is reported from these districts.

Mineral County

At the Tarbox mine near Saltese the shaft is being sunk from 400 to 700 ft. A mill is to be erected to treat second-class ore.

Silverbow County

The February pay-rolls at Butte were the largest on record, totaling $1,800,000. Of this the Anaconda disburses $1,200,000, Butte & Superior $235,000, and North Butte $120,000.

NEVADA

Humboldt County

On April 1 the Seven Troughs Coalition pays 24c per share.

The 150-ton mill of the Rochester Mines Co. is to be enlarged to 300-ton capacity, at a cost of $75,000.

At the tungsten mine of J. W. Patterson and W. Nelson, four miles west of Toy, a 15-ton mill is to be erected. Thirty inches of ore assays 5% tungstic acid, and 72 in. contains 1%. The vein at the surface is in a contact of lime and granite.

Mineral County

At the Silver Dyke tungsten property at Sodaville there are 85 men employed, soon to be increased to 150. Large shipments are made regularly.

Nye County

The geology and ore-deposition at Tonopah is discussed by J. E. Spurr in a 57-page paper contributed to *Economic Geology* for December, 1915. He gives a history of geologic investigation at Tonopah since 1902, progress of development and modifications of geologic views, results of recent study, Mizpah trachyte, calcitic andesite, analyses of rocks, Montana breccia, West End rhyolite, Midway andesite, mineral veins (those that have made Tonopah are confined to the Mizpah trachyte), periods of vein-deposition, temperature of rocks, and the complex faulting.

Considerable importance is attached to the Murray vein in the Tonopah Extension mine, where at a depth of 1540 ft. it is 32 ft. wide of good grade.

Fifteen tons of ore daily is being broken from the vein recently cut at 950 ft. in the Rescue-Eula. One lot returned $21.50 per ton at the mill. The vein is 5 ft. wide, the ore containing black sulphide, ruby, and nearly pure silver.

Tonopah mines last week produced 9521 tons of ore worth $196,638.

During February the Belmont produced 252,822 oz. bullion from 12,300 tons, with $108,221 profit. The Tonopah Mining Co. shipped 142,295 oz. from 6896 tons, with $50,635 profit.

TEXAS

Brewster County

(Special Correspondence.)—An investigation of the property of the Terlingua Quicksilver Mining Co. has recently been completed by Edward Thomson of New York for people in that city. Reports obtained from a reliable source show it is likely that another of the few remaining idle properties will soon be on the producing-list again.

H. Watenberger, of Kansas, who owns some valuable claims adjoining the Chisos Mining Co.'s holdings, is also contemplating an early resumption of work; so is the Dallas Mining Co. of the Big Bend district.

The Study Butte Mining Co. reports good progress and results with its development. One shipment of metal has been made, and the company expects to be making them regularly from now on.

Terlingua, March 8.

UTAH

Beaver County

The Majestic Mines Co. reports that between September and February the Old Hickory mine produced 4103 tons of ore yielding 5759 oz. silver and 249,945 lb. copper, netting $17,483 at the smelter. Work at the Hoosier Boy, Harrington-Hickory, Vicksburg, and O. K. mines has been satisfactory.

Salt Lake County

During 1915 the Utah-Apex company produced 4000 oz. gold, 560,000 oz. silver, 2,400,000 lb. copper, and 32,000,000 lb. of lead. The lead output is now at the rate of 50,000,000 lb. per year.

Summit County

Preliminary work has been started on the Daly-Judge electric smelter.

Development in the Three Kings is reported as good. Two strong fissures have been cut.

In the suit of the Conkling Mining Co. v. the Silver King Coalition Mines Co., an extra-lateral dispute, the U. S. Court of Appeals decided that the plaintiff owns a quarter and the defendant three-quarters of the property, reversing the previous judgment of the District Court. About $1,000,000 of ground must be adjudicated.

WASHINGTON

By April 1 mining companies operating in the Coeur d'Alene, Idaho, and British Columbia will have paid $3,188,834 in dividends for the first quarter of the year. Of this amount $2,287,885 was contributed by seven Idaho and $900,949 by six British Columbia companies, and it will increase the grand total of net profits for eastern Washington, interior British Columbia, western Montana, and all of Idaho to $86,557,070, including those companies now dormant or absorbed by other corporations. The following table shows the amount of dividends that will be paid in the first quarter of the current year by the operating companies, together with the grand total to April 1:

Coeur d'Alene

Company.	1916.	Grand total.
Bunker Hill & Sullivan	$327,000	$17,100,000
Caledonia	208,400	1,091,131
Federal	120,000	15,405,545
Hecla	300,000	4,055,000
Hercules	600,000	8,600,000
Consolidated Interstate-Callahan	697,485	3,245,930
Stewart	.....	2,043,425
Success	135,000	1,730,000
Total	$2,387,885	$53,271,031

British Columbia

Company.	1916.	Grand total.
Canadian Consolidated M. & S.	$175,282	$ 2,495,418
Crows Nest Coal	93,189	2,276,861
Granby	224,978	5,951,901
Hedley	120,000	1,883,520
Le Roi No. 2	.....	1,546,749
Mother Lode	137,500	137,500
Rambler-Caribon	.....	420,000
Standard	150,000	1,950,000
Total	$900,949	$16,661,952
Grand total	$3,288,834	$69,932,983

Ferry County

(Special Correspondence.)—It is reported that a contract for the first 250 ft. of a 1000-ft. vertical double-compartment shaft in the ground owned by the Republic Consolidated Mines Corporation has been let to George S. Bailey, the trustee in bankruptcy of the Republic Mines Corporation. The former company owns the Lone Pine, Pearl, and Surprise claims, but on which a shaft is to be sunk information is not yet available.

On March 10 an explosion occurred in the compressor-room of the power-house at the Knob Hill mine. The only person in the room was Joe Wiseman, the engineer, who saw a small place on fire. Instantly the explosion followed, and the whole room was filled with smoke and fire. Wiseman, a careful man, was blinded with the smoke, but attracted a number of workmen who were coming out of the mine. He was severely burned. The compressor-room was consumed, but the building adjoining was saved.

Some machinery has been hauled from the Great Northern Railway depot to the San Poil mine for the West Side Mining Co., a new corporation here.

Republic, March 10.

The old San Poil mine and mill at Republic has been taken over under a five-year lease and bond for $150,000 by the West Hill Mining Co., recently organized by Inland Empire men. The bond calls for yearly payments of $30,000, and 10% of the smelter returns for ore shipped is to be applied on the purchase price. D. M. Drumheller, Jr., is manager for the new corporation, and he already has put 20 men on preparatory work. The mill, a 75-ton daily capacity cyanide plant, will not be started yet, but may be operated later. A contract has been secured from the Canadian Consolidated company for 2000 tons of ore monthly, to be treated at its smelter at Trail, B. C., and the first shipments will be forwarded in a few days. The San Poil is a gold producer, the product, according to engineers' reports, assaying from $7 to $15 per ton. It was extensively developed by the former owners, underground work and equipment costing not less than $300,000. It is said that there are 30,000 tons of ore blocked out ready for extraction above the 300-ft. level. The new operating plans contemplate extending the 400-ft. level to cut the shoot showing in the upper workings, and later a shaft will be sunk to 800 ft. depth.

CANADA

British Columbia

On March 31 the Hedley Gold Mining Co. pays its quarterly dividend of 3%, and an extra of 2 per cent.

The Silver Hoard Mining Co. will erect a 200-ton mill near Ainsworth this summer. George Chew is president and general manager.

The Slocan Star mine at Sandon has been examined, and the company will re-model and enlarge its mill to 250-ton capacity, to treat the silver-lead and zinc ores. Bonds worth $80,000 were issued last week for this purpose.

On account of the bad weather in January the Standard Silver-Lead company suffered a loss of $26,329. About $10,000 will be paid by the Canadian Pacific railroad for five cars of concentrate lost on the lake. February will also be a poor month. On April 10 will be paid 2½c. per share, or $50,000.

Ontario

As explosives and steel prices have advanced so much, the higher quotes for silver have not balanced this increase at Cobalt, so economy is the order of the day.

During February the Nipissing high-grade and low-grade mills treated 124 and 6954 tons of ore, yielding $72,146 and $99,710 respectively, a total of $171,856. The refinery shipped 535,514 oz. silver from all sources. No. 81 shaft, to develop the Cobalt Lake fault-vein, is down 310 ft. The fault was cut at 270 ft., being of no value.

KOREA

The Seoul Mining Co., operating the Suan Concession in Whanghai province, Chosen, reports the following results for February:

Ore treated, tons	14,420
Mill operating, days	24
Bullion	$ 62,500
Concentrate	$ 57,950
Total recovery	$120,450
Expenses	55,000
Operating profits	$ 65,450

Copper is figured at 12c. per pound.

MEXICO

Sonora

The Moctezuma Copper Co. at Nacozari decided to send its employees to Arizona, on account of the Mexican trouble. The general manager, J. S. Williams, Jr., and General Calles conferred on the question.

PERSONAL

Philip Argall is at New York.

Horace V. Winchell was at Salt Lake City this week.

Ernest Bamberger, of Salt Lake City, is at the St. Francis hotel.

C. E. Juhlin has been examining the Burning Moscow mine, in Utah.

E. L. Larison and F. F. Frick of Anaconda are at the Bellevue hotel.

F. C. Alsdorf is examining properties in Nevada and northern California.

James Hoatson, of Calumet, Michigan, was in San Francisco last week.

D. M. Riordan is expected in San Francisco on his return from New York.

John Cooper has passed through New York on his way from London to Zacatecas.

R. R. Leslie, manager of the Butters Divisadero mine, in Salvador, is here on a holiday.

R. S. Botsford has gone to the Bodaibo region, in Siberia, to report on dredging conditions.

Karl Eilers, a director of the A. S. & R. Co., has been in San Francisco on a tour of inspection.

John R. Mitchell and P. H. Argall have been examining mines along the Mother Lode and in Nevada.

H. R. Bostwick, A. R. Weigall, and J. F. Mitchell-Roberts sail on the *Tenyo Maru* for Korea on March 28.

Frank O. Jasmer has returned from the Republic of Honduras and expects to go to Mexico in the near future.

F. C. Lincoln, of the Mackay School of Mines, Reno, is gathering information and statistics on Nevada mining.

George T. Coffey, superintendent of the hydraulic department of the Yukon Gold Co., has returned to Dawson from Oakland.

H. A. Guess, formerly consulting engineer, has been appointed managing director of mining department of American Smelting & Refining company.

E. E. McCarthy, dredge superintendent for the Yukon Gold Co., arrived from New York in San Francisco March 15, where he will be for two weeks at the Palace hotel.

W. A. Neill, for many years engineer of the mining department of Allis-Chalmers Co., has moved to Denver and become associated with the Dorr Cyanide Machinery Company.

William F. Jahn, for the past three years mill superintendent for the New York & Honduras Rosario Mining Co. at San Juancito, Honduras, C. A., has resigned and will leave shortly for the United States.

F. H. Brownell of Seattle, chairman of the board of directors of the Federal Mining & Smelting Co., will succeed Harry L. Day of Wallace, Idaho, as president and general manager. H. A. Guess of Wallace becomes managing director.

A. L. Blomfield, for many years in the employ of Bewick-Moreing & Co., as metallurgist, and for the last eight years mill superintendent of the Golden Cycle mill at Colorado Springs, has become associated with the Dorr Cyanide Machinery Co.

S. R. Elliott of Negaunee, Mich., is now general superintendent of Cleveland-Cliffs Iron Co., a new position that takes some of the work formerly directed by M. M. Duncan whose title changes from agent to general manager. A. J. Youngbluth has been made purchasing agent. The company now controls over 20 mines.

The regular meeting of the Missouri Mining Association was held on March 13, at the School of Mines, Rolla. An address was given by Philip N. Moore, first vice-president of the A. I. M. E. Following this, an enjoyable smoker was held. Officers of the Association are as follows: L. W. Eilers, president; J. G. Reilly, vice-president; W. A. Shaw, secretary; and H. A. Kluge, treasurer.

THE METAL MARKET

METAL PRICES

San Francisco, March 21

Antimony, cents per pound	41
Electrolytic copper, cents per pound	27.75
Pig lead, cents per pound	7.50—8.45
Platinum, soft metal, per ounce	$88
Platinum, hard metal, 10% iridium, per ounce	$95
Quicksilver, per flask of 75 lb	$210
Spelter, cents per pound	22
Tin, cents per pound	46
Zinc-dust, cents per pound	30

ORE PRICES

San Francisco, March 21

Antimony, 50% product, per unit, of 1%, or 20 lb.	$2.25
Chrome, 40% and over, f.o.b. cars California, per ton	14.00
Magnesite, crude, per ton, f.o.b.	8.00
Magnesite, plastic, no iron and lime, calcined, ton	25.00—30.00
Magnesite, refractory, 1% iron, dead-burned, ton	35.00
Manganese, 50% metal, 8% silica, per ton	12.00
Tungsten, minimum 60% WO_3, per unit of 20 lb.	65.00—75.00

At Boulder, Colorado, 60% tungsten ore jumped from $75 to $90 per unit last week.

New York, March 15.

Antimony ore is firm at $2.70 to $2.75 per unit.

Tungsten ore for forward delivery exceeds $70 per unit, and spot, if offered, would easily bring $80.

Spot 80% ferro-manganese, a product of the blast-furnace, has been sold in car-load lots at $350 per ton. Ferro-manganese containing 50% manganese, is held at $5 per unit. Spiegeleisen, containing 20% manganese, has sold at $60 per ton. All of these products, indispensable in the making of steel, are exceedingly scarce.

EASTERN METAL MARKET

(By wire from New York.)

March 21.—Copper producers are firm but quiet; independents control the lead market; zinc is firm and more active.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending	
Mch. 15	56.75	Feb. 9	56.79

After a quiet but steady market, silver has suddenly moved up. There has been a large outflow of silver from the Indian currency reserve for various purposes, amounting to 65,500,000 oz. Shipments of metal from London to India to February 23 are 7,260,000 oz. less than in the period of 1915.

Silver worth $258,700 (462,000 oz.) was shipped last week from San Francisco to China.

COPPER

Prices of electrolytic in New York, in cents per pound.

Date.		Average week ending

Braden produced 2,842,000 lb. in February (29 days), against 4,556,000 lb. in January (31 days).

Miami expects to produce 50,000,000 lb. in 1916.

Rio Tinto has declared $8.10 per share on the ordinary shares, against $1.80 in the first half of 1915.

Reports from the copper companies for 1915 are now coming to hand and will be reviewed in the 'Press' as early as possible.

LEAD

Lead is quoted in cents per pound, New York delivery.

Date.		Average week ending	
Mch. 15	7.25	Feb. 9	6.12
" 16	7.35	" 16	6.26
" 17	7.45	" 23	6.30

June	3.90	5.75	....	Dec.	3.80	5.34	....

On account of the advance in lead, Joplin producers consider $100 per ton for 80% product justified, and expect to see that figure soon.

The Consolidated Mining & Smelting Co. of Canada pays $2.50 per share on April 1, a total of $175,282.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. Prices, in dollars per flask of 75 pounds:

Week ending			
Date.		Mch. 8	250
Feb. 23	300	" 14	235

June	38.60	90.00	.....	Dec.	53.10	123.00	.....

The market continues weak. It is reported that Great Britain has eased the embargo on metal from Europe, which may result in imports to the United States, further lowering the price.

The New Idria company pays $1 per share ($100,000) on March 31. The Oceanic mine in San Luis Obispo county, California, has been sold for $100,000. Its output is over 1000 flasks per year.

ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery, in cents per pound.

Date.		Average week ending

Tin is firm at 52 cents.

Eastern Metal Market

New York, March 15.

The lead market has run away, despite all efforts of the leading producer (the A. S. & R. Co.) to hold it in check. The spot supply is scarce, and it has been eagerly sought by both domestic and foreign buyers. Interests on the Pacific Coast have offered 8c., delivered on the Coast, for metal intended for export to Japan, China, and Russia. This price is equal to 7.50 to 7.60c., St. Louis. The A. S. & R. Co. has advanced its nominal quotation to 7c., New York, but is practically out of the market. Copper is dull, but prices are firm, a slight weakness which developed last week quickly disappearing. Zinc has declined steadily for days, but the bottom has apparently been reached. The domestic demand is light, but a more depressing influence is the decline of £25 per ton in the London market in less than 10 days. Tin has touched 56c., and is still strong because of the scarcity of the supply available for March delivery. Antimony continues strong. Aluminum is a little weaker.

Exports of metals in unmanufactured form are not so heavy compared with those of recent months, but large quantities are going abroad in the form of munitions. The aggregate value of munitions exported in the week ended March 11 was $17,370,243, against $11,418,241 in the previous week, and $5,997,439 two weeks ago. Shipments of cartridges in the week ended March 11 totaled $1,729,556, against $696,774 and $93,984, one and two weeks ago. The value of other munitions are proportionate. For the seven months ended January, 1916, exports of miscellaneous iron and steel totaled $64,844,131, while for the same period ended January, 1915, they were $8,554,873.

The steel market is a run-away, and prices are difficult to gauge.

COPPER

Since the recent strike at the Ansonia mills of the American Brass Co. the demand for copper has been light, and for the past few days the market has been very dull. The strike only lasted a week, but it seems to have frightened consumers into stopping to realize the prices they were paying. A further influence on prices has been the congestion of freight on the New York, New Haven & Hartford railroad, which has halted deliveries from time to time. The embargo was raised for a period of four days ended at midnight March 14, and in this time a great deal of copper, as well as other metals and materials, were forwarded to their destination. In the latter part of last week the market weakened a little because second-hands were offering at concessions. It was possible to shade 26.50c., for near future deliveries, although the larger sellers adhered to their minimum quotations. Consumers are well covered for the present, as they should be in view of the vast movement of a few weeks ago, consequently there is little or no buying of spot copper. The next large buying movement probably will be for deliveries in June and later. Spot electrolytic hangs around 27.50c., cash, New York. Lake is nominally quoted at the same figure. Electrolytic at London is unchanged at £136. Exports up to and including March 14 totaled 6833 tons.

ZINC

Except for steady recessions in price the zinc market has been without feature during the past week. Needless to say, the demand has been dull. The quotation for prompt yesterday was 16.75c., New York, and 16.50c. St. Louis, both of which were about ¼c. above the quotations of the previous day. April and May were quoted at 16c., St. Louis, and June at 15c. It is felt that the bottom has been reached, and that from this time on quotations will advance, or at least hold their own. Since March 6, when the British Ministry of Munitions permitted the resumption of trading (under certain restrictions) on the London Metal Exchange, spot zinc has declined from £110 to £85, a drop of £25. Though details are lacking, it is felt here that the Ministry is making a minimum price effective, and is doing it successfully, which was not done in copper. Exports of this month, up to and including the 14th, totaled 906 tons.

Sheet-zinc is quoted at 25c., f.o.b. mill, carload lots, 8% off for cash.

LEAD

The market is a run-away one of the worst type. Spot lead is scarce, and both domestic and foreign buyers are clamoring for what is to be had. Interests on the Pacific Coast have been heavy buyers for export to Japan, and to Russia, by way of Japan, and have bid 8c., delivered on the Coast. This is equal to 7.50 to 7.60c., St. Louis. The result has been a complete upset to Eastern prices. The A. S. & R. Co. raised its nominal quotation yesterday to 7c., New York, and 6.92½c. St. Louis, (an advance of $8 per ton) but it is not selling at these levels. The independents are selling what they have at 7.50c., New York, and up to 7.62½c. St. Louis. The average of St. Louis prices has run higher than those at New York, and it is exceedingly hard to tell just where the market stands. The average New York price yesterday was 7.25c., and that at St. Louis 7.37½c. It is plain that efforts to restrain the market from running away have been entirely unsuccessful. The London market, contrary to that for spelter, has gained strength in the past week, and now stands at £35 5s. for spot. Exports this month, up to and including yesterday, totaled 1678 tons.

TIN

Spot tin is scarcer than ever, and it is increasingly difficult to obtain licenses to ship from London. American consumers are partly to blame for the situation. A few of them whose wants were well covered with tin they had in warehouse have obligingly helped out some of their less fortunate friends, thereby violating the agreement they entered with the British authorities. Last Thursday (the 9th) the market was highly excited, probably 500 tons changing hands at prices that ranged from 52 to 56c., all in the course of the afternoon of that day. The trouble is that brokers fear they will be caught short on their commitment for the month, and this is certain to happen if they sell metal which cannot be replenished before the end of March. Arrivals of the month only total 368 tons, but there is afloat 6735 tons. Relief for the present situation hinges to a great extent on the arrival of the steamer *Suruga* from Singapore with 1135 tons. She was to have arrived the 8th, but has been delayed, and it is uncertain whether her cargo will be available for March delivery. The quotation yesterday was 54c., but strong at that figure. While the situation is a problem for the moment, it is a passing one, as the large quantity of tin afloat indicates.

ANTIMONY

The market continues firm and the quotations for Chinese and Japanese grades show no change. Spot is quoted at 44 to 45c., duty paid. March and April shipments from the Far East have sold at 34½c. Needle antimony is in demand, and March shipment from the East has been done at 23½ cents.

ALUMINUM

Spot aluminum, 98 to 99% pure, is easier at 57 to 60 cents.

BOOK REVIEWS

THE MECHANICAL WORLD POCKET DIARY AND YEAR BOOK FOR 1916. P. 230. Ill., index. The Norman Remington Co., Baltimore. For sale by MINING AND SCIENTIFIC PRESS. Price, 25 cents.

This is the twenty-ninth year of the publication of this valuable pocket-book. Some material has been added and other parts brought up to date. It contains a number of tables and other data, principally useful to the mechanical engineer, but of value to the engineer in other lines. A diary for 1916 is included. Altogether the purchaser certainly gets a great deal for his money.

CONCRETE. By John C. Trautwine, Jr., and John C. Trautwine, 3d. P. 126. Ill., index. Trautwine Co., Philadelphia. For sale by MINING AND SCIENTIFIC PRESS. Price, $1.

This book contains the portions of the 'Pocket-Book' that relate to concrete. The first section reprinted is on strength of materials, the next sections are, in order, cement, sand, mortar, concrete, and reinforced concrete. The notes on the last named, while necessarily condensed, contain a good summary of the principles of design in that material. Next comes a division on experiment and practice, which contains a summary of the data obtained concerning concrete and related subjects by a number of observers. Divisions on specifications and on cost data are included and there is also a price-list, bibliography, and index. The book should be of as much value to those interested in concrete construction as the regular pocket-book is to engineers in general.

DAMS AND WEIRS. By W. G. Bligh. P. 206. Ill., index. American Technical Society, Chicago. For sale by MINING AND SCIENTIFIC PRESS. Price, $1.50.

This is a brief but fairly comprehensive treatise upon the subject. The design of gravity dams of masonry and concrete is first considered and examples with profiles given of a number of dams actually constructed. The effect of percolation under porous foundations is discussed. The next division is overfall dams and weirs, then single and multiple-arch dams, and hollow-slab buttress dams. Submerged weirs founded on sand and methods of preserving stability in spite of percolation are then considered. The last division is open dams or barrages. Earth dams are not considered anywhere in the volume. The book is well illustrated. It would have been made more interesting, at least, if the geological situation of the various structures had been always given.

PRINCIPLES AND PRACTICE OF COST ACCOUNTING. By F. H. Baugh. P. 166. Index. F. H. Baugh, Baltimore. For sale by MINING AND SCIENTIFIC PRESS. Price, $3.

There is a familiar story concerning the man who installed a cost-keeping system in his factory, but who was unable to tell whether or not it helped his business because the entire force had been obliged to suspend business to work on the cost system. With due allowances for exaggeration, it is undoubtedly true that many manufacturers have failed to get the best returns from their plants because cost systems seemed to them nothing but a useless mass of printed form and filing-cases. The author of the present volume has wisely confined himself to an explanation of the principles underlying cost keeping with only enough concrete examples to illustrate these principles, leaving the arrangement of details for a particular factory to the reader. As a further aid to clearness, 'efficiency engineering,' or as the author prefers to call it, 'factory management' is separated from cost-keeping, and the latter subject only is discussed.

RECENT PUBLICATIONS

MINERALS OF OREGON. By Graham John Mitchell. University of Oregon Bulletin. P. 61. Eugene, 1915.

ALPHABETICAL HAND-LIST OF NEW ZEALAND TERTIARY MOLLUSCA. By Henry Suter. P. 28. Tables. Government Printer, Wellington, 1915.

GEOGRAPHY OF THE FOX-WINNEBAGO VALLEY. By Ray Hughes Whitbeck. Wisconsin Geological and Natural History Survey Bulletin XLII. P. 109. Ill., maps, index. Madison, 1915.

PRELIMINARY REVIEW AND ESTIMATE of mineral production of British Columbia in 1915. By Wm. Fleet Robertson. Bulletin No. 1, 1916. P. 50. British Columbia Bureau of Mines, Victoria, B. C., 1916.

The total production was $29,299,564, an increase of $2,910,739, of which placer gold was $180,000 more, lead $145,922, copper, $3,884,749, and zinc $1,208,378.

MAGNETIC AND OTHER PROPERTIES OF IRON-SILICON ALLOYS, MELTED IN VACUO. By Trygve D. Yensen. University of Illinois Bulletin No. 83. P. 67. Illustrated. Urbana, 1915.

It is shown that silicon increases the mechanical strength of iron in almost direct proportion to the amount added, until the maximum strength is reached with a silicon content of about 4.5%. The elastic limit of this alloy was shown to be 94,000 lb. per sq. in. and its ultimate strength 105,000 pounds.

THIRTY-SIXTH ANNUAL REPORT of the Director, George Otis Smith, of the Survey for the fiscal year ended June 30,1915. P. 186. Maps, index.

This publication contains a review of the immense amount of work done by the department, and shows that it is of great importance to the country.

PRODUCTION OF METALS AND ORES IN 1913 AND 1914. By J. P. Dunlop. P. 11.

A total of 113,579,697 tons of ore was mined in 1914. The metals were valued at $795,704,240.

ZINC AND CADMIUM IN 1914. General report. By C. E. Siebenthal. P. 56. Chart.

A RECONNAISSANCE OF THE COTTONWOOD-AMERICAN FORK MINING REGION, UTAH. By B. S. Butler and G. F. Loughlin. With notes on history and production by V. C. Heikes. Bulletin 620-I. P. 62. Map.

A timely discussion of a district of great promise. Abstracts will be made at an early date.

NOTES ON THE FINE GOLD OF SNAKE RIVER, IDAHO. By J. M. Hill. Bulletin 620-L. P. 24. Maps and diagram.

THE AZTEC GOLD MINE, BALDY, NEW MEXICO. By Willis T. Lee. Bulletin 620-N. P. 6. Illustrated.

Interesting notes on an old producer recently re-opened.

EDITORIAL

T. A. RICKARD, Editor

HONDURAS passed a new law on February 15; this is intended to check the holding of mining property without working. Forfeiture follows inactivity. Moreover, the amount of territory to be granted for mining purposes is now limited to 200 hectares, or 494 acres; nor will locations be allowed on ground already the site of a town. Finally, a 5% *ad valorem* tax is levied on gold and silver exports, and a specific tax of 10 pesos, or $3.84, per ton on refinery products and precipitates for export.

ARIZONA holds the first place among the States of the Union as a producer of copper. In 1916 the total output is anticipated, by the Arizona State Bureau of Mines, to reach 268,500 tons, as compared with 207,440 tons in 1915 and 182,600 tons in 1914. The Phelps-Dodge group is credited with 70,000 tons and the Inspiration with 55,000, the latter being the chief factor in the increase to be made by the State as a whole. Arizona produces about one-third of the United States output and one-fifth of the world's supply of copper.

REVIVAL of prospecting may bring clashes with the Forest Service, owing to lack of public knowledge concerning the rules governing mineral exploration on Forest Reserves. We are informed that the Forestry Relations Committee of the American Mining Congress, under the chairmanship of Mr. Carney Hartley, at Denver, is prepared to furnish information on the subject in such a way as to facilitate prospecting and prevent friction with the duly constituted authorities. Write to him if you need information on the subject.

STATISTICS are out of repute in these days, when figures are juggled either to conceal ignorance or to promote a policy. The Department of Commerce is being attacked for issuing a statement that American dye-works are producing coal-tar colors at the rate of 15,000 tons annually, when expert unofficial information shows that only 6500 tons of dye-stuff is now produced in this country. We agree with *American Industries* that the Federal government ought to set a better example of accuracy in these matters.

ONE-CENT postage is again being advocated by the association formed for that purpose at Cleveland. It is hoped to obtain this reduced rate for local delivery at first and extend the concession for all domestic letters later. Fifty-three separate bills for this purpose have been introduced in Congress during the present session. It is stated that the 2-cent rate is just twice more than the cost, and that the Government earns a surplus of $75,000,000 per annum on its letter postage. It is claimed by the advocates of 1-cent postage that the Post-Office was not organized to make a profit but to serve the people. Cheap postage is a great stimulant to social and industrial progress.

SILVER rose to 60¾ on the 24th instant. The demand from India has improved and an increased amount is being absorbed for subsidiary coinage in Europe. In any event, it is a good thing for the Western miner, who wins silver nowadays largely as a by-product. The biggest producer of silver in the United States is the Anaconda Copper Mining Company, which contributes 8,000,000 ounces annually to the mints. Among purely silver mines, the Nipissing, in Canada, yielded 4,610,050 ounces last year and the Canadian Mining Corporation, also at Cobalt, 4,503,000 ounces. The Tonopah Belmont normally produces 3,700,000 ounces per annum, while the total output of Nevada last year was 14,500,000 ounces.

APPARENTLY the scientific commission sent to the Panama Canal has not been able to give a particularly cheerful report on the geologic conditions modifying the stability of that great highway of maritime commerce. The slides that were the cause of the recent block are being removed at the rate of 1,000,000 cubic yards per month, and 9,000,000 yards will have to be dredged, but traffic can be resumed long before this work has been completed. A re-opening is announced for April 15. Sliding of the ground, in the Culebra cut particularly, will continue to give trouble, but to a diminishing degree and not enough to interrupt navigation seriously. A repetition of the recent experience is considered most unlikely. In order to minimize the unfavorable conditions it is necessary to employ every practicable device that will divert the water falling as rain on the sliding ground. This can be done, so the scientific commission suggests, by bordering the slides with vegetation, closing peripheral cracks, draining the threatened areas, establishing open drains in the great slides themselves, and using tunnels or 'adits' for a similar purpose. The structural weakness of the rocks of the Canal Zone is recognized, also the possible effect of earthquakes in starting slides, but it is expected that the remedial measures mentioned, and the relief of pressure by unloading certain areas, will suffice to protect the great water-way. About seven feet of water falls in eight months of the year in the Culebra district. No wonder that it is so difficult to control the underground seepage, for during the rainy season the level of ground-water is practically at the surface, making the country nothing better than

one big morass. All of which recalls the alternate plan for building a canal in Nicaragua.

NO SURPRISE need be felt that President Wilson should have issued a warning against the sinister influences that are seeking to embroil the United States in war with Mexico. During recent weeks the disreputable portion—much the larger—of the daily press has been publishing all kinds of fictitious stories about events in Chihuahua and elsewhere in Mexico, it has indulged in a lot of nonsense and some plain lying about the American expeditionary force, its movements, and its purposes. Undoubtedly there are "persons along the border who are actively engaged in originating rumors of the most sensational sort" and there are others distant from the border who are playing the same game "for the purpose of bringing about intervention in the interest of certain American owners of Mexican properties." The interests of the mining profession, and those of this technical publication, would, we believe, be advanced by an intervention that would ensure law and order in Mexico, but we have no right to jeopardize the political welfare of the United States and the lives of thousands of our fellow citizens in working insidiously to bring about such a climax. We believe that it is inconsistent with the honor of the United States to interfere in Mexican affairs so long as we recognize the Government of that country, except in so far as that Government gives consent. The time may come when the logic of events will compel drastic action; meanwhile it is our duty to support the President and the moderate policy endorsed by Congress.

THOSE who remember the beginning of the business developed by Meyer Guggenheim's seven sons—now reduced to five—and the first organization of the smelting consolidation in 1898, will appreciate the bigness of the operations now conducted by the American Smelting & Refining Company. The report for 1915 just issued exhibits steady growth and a marked recovery from the depression of 1913 and 1914. A total income of $18,245,731 in 1915 compares with $12,825,530 in 1914. A net profit of $13,873,676 last year compares with $9,589,630 the year before. Metal stocks aggregating $23,618,862 indicate the hostage to fortune that such an enterprise is compelled to carry. From four to five millions is spent annually on the purchase of new property and the construction of additional plant. In Mexico, of course, the company's operations have been unproductive and unprofitable recently. Despite the gloomy outlook, fresh property has been acquired in that distressful country, and Mr. Daniel Guggenheim, the president, expresses his confidence that such investment ultimately will prove advantageous. During the past year the company constructed a tin smelting and refining plant at Perth Amboy, New Jersey, zinc smelting plants at Salt Lake City, Utah, and Sand Springs, Oklahoma, besides a copper refinery at Tacoma, Washington. With this latest addition to its productive capacity the company will be able to smelt and refine 500,000 tons of electrolytic copper per annum, which is equal to half the normal copper production of the world.

DEALINGS in metals in Great Britain have been placed under severe embargo by the Government under an Order in Council. According to *The Financial Times*, this prohibition of speculative dealings in copper, lead, spelter, and iron—tin is omitted—has received public approval in so far as it affects the gambling in war commodities, but grave doubts are expressed as to the check upon 'hedging' operations on the part of consumers and the transactions based upon metals in ores and concentrates while yet in process of treatment. It is claimed that the abnormal prices for zinc and copper, for instance, are due not to speculative dealings in London, but to 'cornering' tactics in New York. It is asked, how can the British government expect to restrain the quotations for copper and zinc when two-thirds of the production of these metals is controlled in the United States? Concurrently, the London *Mining Journal* lays stress on the fact that the control of spelter was at Frankfurt before the War and at New York since then, and yet the British government has failed to grapple with the problem of a domestic smelting of the Australian output, although urgent representations have been made to that effect. The *Financial Times* expresses the fear that the result of interference with the metal trade will be to centralize European dealings at Rotterdam or Amsterdam, where the Dutch have already got a good grip on the tin market. Indeed, the War is going to have a far-reaching effect on the metal trade.

DISCUSSION is good for the correction of error and the disciplining of prejudice. This week the department of our paper devoted to this purpose is enriched by contributions from a number of well-known professional men. Mr. David Cole, himself a busy metallurgist, compliments Professor Austin by making some interesting corrections in regard to the practice at Anaconda. Mr. J. R. Finlay, recently elected president of the Mining and Metallurgical Society of America, corrects an inaccurary of our own in regard to the highest price paid for copper. In response to his mention of the economic consequences of the War upon the metal markets, we shall welcome a discussion of the subject, to which we also made reference in these columns in our last issue. The note by Messrs. Grothe & Carter is interesting, and we may take the opportunity of adding that a letter just received corrects the name of the engineer who devised the make-shift stamp-shoe. It should have been Herbert P. Orr. To Mr. K. C. Li, one of the accomplished Chinese mining engineers to whom we appealed for help in persuading the Chinese authorities to modify their mining regulations, we are indebted for a sympathetic treatment of an international difficulty. Undoubtedly our people often make the mistake of introducing a political element into their business and they are much too apt to despise any methods that are not exactly like their own. For instance, as Mr. E. T. McCarthy suggested in the discussion on Chinese mining

regulations before the Institution in London, they overlook the probability that the evasion of the Oriental is not without method, that the intellect of the educated Chinese is of a very high order, and that the imposition of prohibitive regulations may be only a polite method of effecting a deliberate purpose, namely, of blocking the mining enterprise that threatens foreign complications and domestic unrest. Mr. B. Read contributes an eminently sensible letter on share dealings, treating the subject in a manner entirely consonant with our own views, often expressed. His comments are particularly timely just now when share quotations are inclined to soar recklessly. In regard to the metal quotations, concerning which Mr. Joseph Ralph writes, we are unable to reply explicitly. The New York Metal Exchange, mentioned by Mr. Ralph, is not recognized usually in the settlement for metals in ores, because it is not considered to reflect accurately the current dealings in such metals. Usually its quotations go up quicker and come down slower than those quoted by the technical press. We give consumers' prices as ascertained by our own representative, who is in no way connected with any metal-dealing agency. He discusses the peculiar condition of the lead market in this issue. The whole question of metal quotations needs careful examination. The prices are made not by brokers but by dealers, who are themselves speculators. It would be well if one of the engineering societies would take the matter in hand and appoint a committee to investigate.

Mine Accident Insurance

The useful work of the Industrial Accident Commission is in danger of being discredited by an unreasonable and unfair imposition on the mines operating in this State. Under Chapter 176 of the laws of 1913, known as the Workmen's Compensation, Insurance, and Safety Act, a fund was created to furnish insurance against the liabilities arising thereunder. Under Section 36 of this Act it was stated further that the purpose of this State Compensation Insurance fund was to make provision against the expense of defending any suit for damages, but it was also explained that it was "the intent of the legislature that said fund shall ultimately become neither more nor less than self-supporting." In December 1914, after a hearing, the Commission made a rate of 5%, or $5 per $100 of monthly payroll, for such insurance as is carried by the metal-mining companies operating in California. At that time the insurance companies offered to accept the same risk at 3¼%, and owing to this lower rate they secured most of the business being done. We are informed that they are not only now willing to write such insurance at a rate even less than that quoted at the end of 1914, but did so in 1915. When it became evident that the excessive rate demanded by the State defeated its proper purpose, an effort was made successfully to pass a bill in the 1915 session of the Legislature empowering the Insurance Commission, after a public hearing to establish a minimum rate for all companies carrying insurance under the Act. On October 1, without any hearing whatever, so far as can be ascertained by those most interested, the Commission arbitrarily established the rate at 5%, which minimum has since been increased to 5¾%, thereby endeavoring to force the mining industry to pay the State 2½% more than the rate at which perfectly solvent and reliable companies are willing to underwrite insurance, basing their rate of 3¼% on their experience not only in California and not only in 1914 and 1915, but in other States and for a much longer period of time. The question may be asked whether the mining industry should be compelled to tax its pay-roll 2½% in order to support a State institution that aims to maintain an insurance trust arbitrarily and without advantage to the community? The affair constitutes a grave scandal, which bids fair to destroy the good-will and co-operation that seemed assured between the mine operators and the Accident Commission.

American Capital on the Rand

American participation in gold mining on the Rand is presaged by the recent announcement that Lewis & Marks, a South African firm of considerable repute, had enlisted the interest of several financiers in New York, notably the house of Adolph Lewisohn & Sons, in a proposal to engage in the development of properties at the extreme eastern end of the Witwatersrand goldfield. Mr. William W. Mein, formerly manager of the Robinson mine, has gone to Johannesburg to make an investigation. This, of course, is an interesting event, but it will not be the first occasion on which American capital has participated, for we know that a few well-informed speculators have bought sundry blocks of Rand shares during recent years, notably in the Modderfontein, Brakpan, and other splendid mines in that part of the goldfield to which chief attention has been directed of late. Some of these big mines, such as the Modderfontein group, afford a kind of security unusual in mining. They are well explored and so systematically developed as to give ample assurance of an enormous tonnage of ore having a gold content that has been determined by careful sampling, and capable of being exploited at a cost the exact amount of which can be stated with unusual accuracy. This kind of property is as nearly an investment as a gold mine can be. That does not mean that there may not be an error in the estimate of either the yield or the cost over a long period of years, but the chances for such error have been reduced to a minimum. In short, it is the least risky kind of mining. The factors of uncertainty are labor troubles, fire underground or above, and caving of the workings, all of which are contingencies inseparable from this form of industry—and others also. And then there is one more source of danger to the shareholder who really 'invests' his money in a high-class South African mine, and that is consolidation of the sort that swamped the East Rand Proprietary and Crown Mines, whereby rich ground was

agglomerated with poor ground in order to enable the holders of the latter to get rid of a white elephant and make an advantageous deal. The later history of the Rand can furnish several instances of such abuse of public confidence by financial houses in this way; indeed it is not too much to say that most of the big consolidations were hatched in *vernukerij*, as the Boers call it. However, the more we remember the less we forget, as Kipling says, and if past experience is not too lightly disregarded, it will be difficult to repeat the trick. Making a discount for this contingency and for other possible mishaps, we can still say that the use of capital in such mines is highly attractive. It is possible that the incidence of the War may enable the American financier to participate on favorable terms. The new departure appears to be in excellent hands. We await the sequel with keen interest.

The Qualities of an Engineer

We have received a post-card from the Carnegie Foundation for the Advancement of Teaching requesting us to indicate the relative importance we assign to groups of qualities, which, it is stated, were mentioned in the course of the replies given a year ago to a similar circularization on engineering education. The qualities are grouped as follows:

CHARACTER, integrity, responsibility, resourcefulness, initiative.

JUDGMENT, common sense, scientific attitude, perspective.

EFFICIENCY, thoroughness, accuracy, industry.

UNDERSTANDING OF MEN, executive ability.

KNOWLEDGE of the fundamentals of engineering science.

TECHNIQUE of practice and of business.

Partly because we find ourselves unable to answer offhand and partly because the subject is one of general interest, we propose to discuss the matter with our readers. They will agree that it is worth while to ascertain what are the qualities and aptitudes in demand "in sizing up young men for employment or promotion," as the post-card says. But here we part company with the worthy gentlemen who have formulated the enquiry, for many of the qualities enumerated by them are not required of young men, nor are they associated in their mental equipment in any such way as appears to be suggested. We do not know what is meant by "young men" in this context. To a man of 70 his junior of 50 seems young; to the youth of 25 the latter is old. The inquiry may refer to men just graduated from college or it may mean all those who occupy subordinate positions, as is hinted by the word "promotion." Most of us have known one or two men who at 30 years of age exhibited a precocity of powers that was as admirable as it was abnormal. Such are not typical and the appraisal of them cannot be covered by a post-card. In short, the gentlemen who posted that disturbing missile should start their campaign of enlightenment with a few definitions. That applies to the qualities that they have grouped. Either they give certain words an unusual significance or they have linked qualities that have no close connection with each other. Judgment and perspective are the product of experience; so are understanding of men and executive ability. These qualities may be latent, but they are rarely apparent until a man matures. Nor need executive ability be found in him who understands his fellow men; the latter calls for sympathy, the former for decision. If character is to be identified with integrity, certainly it need not be allied with initiative. A criminal may have initiative *ad libitum*. Apparently character means honor and honesty on the post-card. To us character stands for reliability. One can predicate how a man of character will act under given conditions; a man lacking character is entirely undependable. Common sense and perspective are not related; a man with plenty of common sense may see no farther than his mental foreground, while he with the larger view might yet be unpractical in small matters. In short, the best way to begin a discussion, or an enquiry, is by defining the terms to be used.

However, let us disregard these obscurities and proceed to give attention to the obvious purport of the enquiry. If a young man, say 25 years of age, were to come to us for employment on the staff of a mine or smelter, we should look for intelligence, the desire to learn, a willingness to assist, and loyalty. Thoroughness and accuracy would be in the sequel. As the young man became older and gained in experience, we should look for signs of rarer qualities, such as initiative, judgment, and executive ability. Of course, "the knowledge of the fundamentals of engineering science" must be assumed, as we are supposed to be dealing with young "engineers." We do not understand why the post-card gentlemen should place this kind of knowledge fifth among the qualifications for "engineering success," nor why the last group should be subordinated. For the rest, the manifold work of life calls for diverse qualities; for instance, the two representatives of the American Institute of Mining Engineers included in this Committee on Engineering Education illustrate a typical difference of useful qualities. One of them is a professor, distinguished by scientific insight into the essential principles governing the metallurgy of iron and steel; the other is a mine promoter, endowed with a remarkable understanding of men and their ways. These two have little in common save continuity of purpose and the fact that each started with a "knowledge of the fundamentals of engineering science." In no occupation is there greater scope for many qualities than in mining, and the business related thereto, but success appears to depend upon the power to develop the particular qualities required for the special work each man undertakes—not from choice, it may be. Continuity of purpose counts enormously. The man who "keeps his eye on the ball" is apt to make the strokes that win. A good 'follow through' is essential. The ability to keep one's head in a moment of unaccustomed success or unexpected failure is another factor that makes for ultimate effectiveness. But most of all continuity of purpose, assisted by good health, and luck.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

The Washoe Reduction Works

The Editor:

Sir—In reading Professor Austin's last article describing the present practice in the coarse concentration and flotation plant of the Washoe reduction works, I note some inadvertent errors of statement which I think should be currently corrected:

In his description of the initial process the author leaves the impression with his readers that Hancock jigs are still extensively used in the rehabilitated mill, which is not the case. Professor Austin's written description evidently refers to, and is accurate for, Section No. 1. This section was remodeled in accordance with the Great Falls flow-sheet before flotation had been considered in any way by the Anaconda engineers. In this section Hancock jigs were installed and are still used, but the other seven sections remain practically unaltered down to the point where hydraulic desliming by the Anaconda type classifier is introduced.

The flow-sheet by Mr. Wiggin that accompanies the article accurately portrays the various steps in the process used in the seven sections that were remodeled after flotation had routed the forces of the old order of things, for Anaconda engineers immediately recognized that with flotation on guard many simplifications of process were possible. For this reason, multiple-stage crushing, elaborate hydraulic classification, and complicated methods of concentration went out of style suddenly at Anaconda as elsewhere within the very large field so quickly dominated by what you have pleased to name "the new metallurgy." What happens above the final grinding stage does not matter as long as the insolubles in the concentrate removed are kept within the proper limits, and this meant that the fine points of difference between types of jigs, hydraulic classifiers, and their flow-sheets, which had occupied the stage so long, were of minor, if any, importance. The old equipment of coarse and medium jigs was well adapted for the purpose of impoverishing the ore preparatory to final re-treatment by flotation.

In the last paragraph of the article referred to, the author states that the concentrate as dewatered by the Oliver filter is sent to the smelter carrying but 10% of moisture. By reference to the flow-sheet it will be noted that the moisture is given at 18%, which is more nearly correct.

As the case now stands flotation concentrate may be dewatered in Dorr thickeners to a product that will carry an extreme working minimum of 25% moisture. With this percentage of moisture the product will be fluid enough to be handled in launders with a grade of not less than 1 inch per foot and may be readily pumped when necessary.

Mr. Oliver's drum type of vacuum-filter seems to be the best method we have for reducing the moisture, but the degree of success as expressed in the difference between 25 and 18% seems to be relatively poor. It often costs more money to install the apparatus necessary to remove the moisture from flotation concentrates than it does to provide the frothing apparatus needed to produce them, and a great deal more room is required for these auxiliaries than is needed for the frothing machines themselves. There is a crying need for improvement in the end processes auxiliary to the new art. If the inventors who are trying to perfect "different" frothing machines would turn their attention to defrothing and dewatering machines, there would be less competition and more chance for success.

DAVID COLE.

El Paso, Texas, March 8.

Small Machinery

The Editor:

Sir—In your issue of January 29 appears a letter from Mr. Edgar Hall, writing from Queensland on this subject. That letter is very much to the point and describes just my experience. For years I have tried to make mine-machinery manufacturers see the importance of producing small units for small mines. New mines, as a rule, are not next to trunk lines, nor do millionaires discover or open prospects. In such countries as this, so rich in mineral wealth, but poor in cash, population and transportation facilities, it is still more important to have small units of machinery.

The use of machinery in this country is very limited, not from ignorance, for 90% of the miners know of its existence and would willingly install up to their capacity, which averages 5 to 25 tons per day, but reliable manufacturers do not produce complete units for such small fry. Complete practical small units would have a big sale in all these backwoods regions. By complete unit I mean power, transmission, rock-breaker, stamp-mill or other grinding outfit, concentrator, jigs, flotation, etc., any combination to reduce the weight of the mineral to be shipped from the mine. If any of the mine and mill supply firms would unite the best machinery manufactured into complete small units and undertake to supply these in a compact and light form, I have no

doubt whatever that in a few months many such would be sold even during the War.

R. F. Lees.

Lima, Peru, March 1.

These opinions of mining-machinery buyers in criticism of the manufacturers and selling agencies are interesting. We hope others will contribute.—Editor.

Appraisal of Mining Stock

The Editor:

Sir—Although no sharp line can be drawn between speculation and investment, the speculator generally buys in anticipation of the enhancement of the value of his stock, thereby making his profit, while the investor is content with the dividends alone. Even when buying as an investor, an element of speculation is always involved by reason of the periods of financial prosperity and depression that are usually reflected in the price of stocks. In one year the price may vary over a margin far exceeding the amount of the annual dividend. During periods of depression the stocks are sometimes quoted at a price that does not even reflect the amount spent on development and equipment, let alone the value of the property itself.

But whether or not the trading is due to speculation or investment, there seems to be a tendency on the part of the public to over-value all stocks in general, and mining stocks in particular. It is doubtful if any appraisal is made, as it is improbable that the average investor has sufficient knowledge of the subject of mine valuation to make a proper appraisal even though data were at hand. Usually the data consist of periodic reports of operating companies. Some companies issue reports that are models of what such reports should be, while others are lacking in the necessary information.

The valuation of mining property presents unusual difficulties, as the risks to which the revenue is subjected and the peculiar character of the property itself, necessitate the introduction of certain principles not common to the valuation of other properties. The stock quotation in itself is not sufficient for an appraisal. In addition, the amount of the annual dividend must be known and the life of the mine at least approximated. Many times the purchaser endeavors to justify the high price of the stock by the high rate of annual dividend or the long life of the investment. In reality, long life adds little to the present value and the rate of the annual dividend may be real or apparent depending on whether or not the market value or the par value of the stock is used as a basis of appraisal. The purchaser must take into consideration the fact that, in buying stocks in the open market, he must pay the price as listed on the stock exchange, regardless of the par value.

In mining, unlike many other kinds of investment, provision must be made for the return of the capital invested. As a result, some confusion exists owing to the introduction of more than one rate of interest. There are two distinct directions in which interest must be computed, namely: the internal influence of interest on the redemption of the capital, and the rate of return on the investment after providing for redemption of capital.

If, at the present rate of production, the life of a mine is estimated at 10 years, the rate of the annual dividend must be 18.3% in order to pay 10% on the investment and redeem the capital at 4%, because 45.4% of the annual dividend must be placed in the sinking fund for the redemption of the capital. If, however, the life of the mine is prolonged to 20 years, the rate of the annual dividend need be only 13.4% while 25% of the annual dividend returns the capital at the end of that period.

Just what rate of interest to demand in a mining investment is the crucial question. The rate must take into consideration the nature of the investment with a return commensurate with the risk. With many sound investments offering 5 and 6% at almost no risk, the mining investor is certainly entitled to a more remunerative rate. In the case of a prospect or a small mine in the early stage of production, where the value is wholly prospective, the rate on the investment must be extremely high in order to justify the price. In producing mines where many of the speculative factors have been eliminated by a well established production, the return on the capital invested can be fairly well defined. The cumulative rate of interest, that is, interest on the sinking fund, is fairly well established by savings-banks at about 4% per annum. Well secured stocks and bonds are not available for sinking-fund purposes because the value of a sinking fund lies in the periodic additions to the amounts previously deposited.

The introduction of interest refinements in any appraisal depends much on the nature of the investment under consideration. The value of these factors lies in their assistance in determining the number of years of life required to yield a given interest on the capital invested, and in addition, furnish annual installments, which, if re-invested in a sinking fund, will redeem the original capital at the end of that period.

A stock with a par value of $2 paying an annual dividend of $1, is listed on the stock exchange at $4. The rate of the annual dividend is 25% on the market value and 50% on the par value. In order to pay 10% on the investment and also to furnish annual installments that, re-invested in a sinking fund at 4% will redeem the original capital at the end of the period, requires a life of 6 years. If the stock is quoted at $8, the life required is 24 years. In other words, if the present value is doubled, the life must be quadrupled in order to justify the price if the amount of dividend remains the same.

A long life adds little to the present value and, at the same time, the redemption factor ceases to be of importance. Increase the life of the above annual dividend to 30 years, and the present value is then $8.49, while a further increase of 10 years increases the value but 56c., a total of $9.05. If, however, with the assurance of 40 years of life, 7% is deemed sufficient return on the capital invested, then the present value is $12.42, and the amount that must be added annually to the sinking fund for the redemption of the capital is but 13c., or

13% of the annual dividend. Decrease the life to 10 years, then the present value on a 7% remunerative and a 4% cumulative basis is $6.52 with a 54c. contribution to the sinking fund. As the life increases, the amount that must be annually added to the sinking fund rapidly decreases in accordance with the operation of compound interest. In 10 years, 8.3c. is required to redeem $1 at 4%, 30 years requires 1.8c. while 40 years needs an annual contribution of only 1c. On a 5% accumulative basis, 10 years requires 7.9c., while 40 years reduces the amount to 0.8c.

Although long life adds little to the present value, this present value is very much of a factor in modifying the remunerative and cumulative rates of interest used as a basis of appraisal. A 20-year annual dividend of $1 with interest on the investment at 10% and a redemption of the capital at 4%, has a present value of $7.49. On a 7% remunerative and a 4% cumulative basis, the present value is $9.65.

The value of any stock is based upon its present and prospective capacity to yield dividends, although all stocks are not equally valuable. This discrimination is the essence of any valuation and involves economic considerations of the greatest importance.

Metal Prices

The Editor:

Sir—I note your editorial in the copy of March 11, in which you state that copper is at the highest price since 1873. I think you are a little inaccurate in this, due probably to a conclusion brought about by the depreciated United States currency in war times. Dr. Douglas called my attention to that some years ago and I have recently looked it up. I find that the London price for 'tough' copper (I don't know exactly what that means), in January and February, 1864, was £113 per ton, corresponding to about 24½ cents in American money, per pound. In 1873 the same brand was quoted in London at a high price of £97, corresponding to a little less than 21 cents per pound. Thus you will see that the price of 55 cents, which you mention as having occurred in 1864, is plainly due to depreciation of the currency in which it was quoted.

To the best of my knowledge and belief, copper and lead are both at the highest price since the Napoleonic wars. In fact, it is doubtful whether lead is not at a higher price that it ever sold for before in London; the highest that I find for it being £35 15s. in 1806. Copper, however, was considerably higher during the Napoleonic wars than it is now, although it started from a higher level before those wars. For instance, in 1790 it was quoted at £86 per ton and reached a maximum of £198 per ton during the latter part of 1805 and the early part of 1806. The average price in London on this occasion in 1913 was about £69½ for standard copper, say, £72 for electrolytic. Thus, while this present price of electrolytic copper in London, which is supposed to be about £136 plus freight from New York, is the highest since that time, it is not so high either actually or relatively to former prices as it was during the Napoleonic period.

The question of the stimulation of prices by great wars is an interesting one, and while I understand that your policy is not to say anything about the War from a political standpoint, I suggest that the subject is worth discussion from an economic standpoint and I would be glad if you would publish this letter.

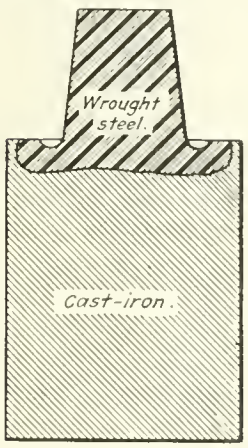
Improvised Stamp-Shoes

The Editor:

Sir—During a period when it was impossible to import steel shoes and dies for stamp-batteries owing to lack of communication, Mr. Hubard P. Orr, mechanical engineer in charge of the shops and foundry of one of the large mining companies here, successfully tided over the shortage of shoes by means which it seems to us are worthy of record.



The necks of worn-out shoes, after being thoroughly cleaned on the face, were put into sand, the surface liberally sprinkled with borax and hard iron poured centrally into the mould formed by a pattern of the shoe, the result being complete fusion of the iron to the steel neck. See sketch enclosed. These shoes are running at present without showing any sign of weakness.

This may have been done elsewhere, but had not been heard of here and no less credit belongs to Mr. Orr.

Chinese Mining Regulations

The Editor:

Sir—Your editorial on this subject in your issue of March 4, affords me an opportunity of passing a few words of comment.

I quite agree, in a broad way, that the obnoxious regulations imposed upon mining capital in China were, and still are, very detrimental to the development of our national resources and the tremendous possibilities associated with it. Foreign capital certainly has so far avoided Chinese mining, or has only approached it in almost negligible quantity, but notwithstanding this, those few who did venture have, I think it safe to assert, received a handsome return on their capital.

That the mining laws do require a careful and thorough sifting by a capable board is my considered judgment. An ideal board to take charge of the revision of the regulations should, I think, be composed of four kinds

of metalers). Chinese mine-owners, experienced mining engineers, legislators familiar with mining laws, and persons familiar with Chinese mining customs. Such a board, if in earnest, would be possessed of everything necessary to accomplish the desired object, and fill in the gaps which are so conspicuous in the existing regulations.

As a mining engineer myself, I feel that the sooner the Chinese authorities become apprehensive of the beneficial effect it would have on our country and the sooner they do away with the present easy going individuals who head some of the wealthiest institutions, the sooner will the dawn of a new era descend upon us and bring with it prosperity and wealth to the Chinese merchants, as well as to the Chinese workmen.

If I am not intruding too much on your valuable space, perhaps I might add that my advice to foreigners who go into China for the purpose of investing in Chinese mines would be to debar themselves completely from the idea of introducing a political element into their business, for any purpose whatever. The Chinese business-man is not a politician, he dislikes the game intensely, but at the same time, like any other man, he favors not the foreigner who tries to become master in his (Chinese) home. I do believe that some good is bound to come as a result of your persistent soundings and your appeal to the youthful and educated Chinese students, who have distinguished themselves in the American and European universities to assist in the rejuvenating of China. This appeal should deeply resound in the hearts of every one of them. In conclusion, I would add that my only desire is that the echo should be carried deep into the ears of those in whose hands the destiny of our country lies.

K. C. Li,
Secretary Hunan Mining Board.

New York, March 16.

Metal Quotations

The Editor:

Sir—Will you be good enough to explain the existing differences between copper prices as stated in the daily press and those quoted in the trade journals. As yet the highest weekly average for electrolytic has been 27.25c.; for example, in the week ending February 23, and the average for the month of February, 26.62; yet the Associated Press has been consistently advising a figure of about 28.50 for the past several weeks. This matter has become so monotonously misleading that I asked for explanation from the editor of the *Salt Lake Tribune*: in reply to which I was informed that the Associated Press simply advise the actual market conditions on the New York Metal Exchange and reflect existing conditions. Approximately there is a difference at the present time of 2c. per pound on electrolytic as between the advices daily given by the Associated Press and what is reported in the trade and professional journals. What I would like to know is: When the Associated Press advises that the metal exchange quotes copper as "Steady; electrolytic, near by, 28.00 to 28.50," as is the case this morning, can a person buy at a less figure or not? If the metal can be bought for approximately 2c. per pound less than this purported market price—and it evidently can be so purchased, and is—then where is the basis for the fictitious 28 or 28.50? And that the term 'fictitious' is not an exaggerated one any seller of crude copper ore can readily ascertain for himself by the simple process of making shipments.

This difference has not always existed in such a marked manner; and although the two authorities have rarely been in exact alignment with each other, yet when copper was in the neighborhood of 15c. the difference would be only about 25% of what is the case now that a 'daily quotation' of 28.5c. is in evidence. I have before me as I write a settlement sheet with electrolytic at 17.28, when the previous week's average was about 17.60; another settlement quoting 15.85 with a previous week's average of 16.50; and away down the list the greatest difference is about 0.85 of a cent. But now we have persistent 2c. differences.

Joseph Ralph.

Salt Lake City, March 16.

Alunite in Utah

The Editor:

Sir—In editing my article on 'Mining in Utah,' which appeared in your issue of March 18, you have made me say that "the recent investigations of the newer discoveries of alunite at Marysvale resulted in the conclusion that they were not of commercial value," when what I did say was that "the recent investigations of the newer discoveries of alunite at Marysvale and in Beaver county, resulted in the conclusion that the Beaver County deposits were not of commercial value." I trust you will make the correction that a wrong may not be done the owners of new alunite discoveries in the Marysvale district.

L. O. Howard.

Salt Lake City, March 21.

[Marysvale is in Piute county and close to Beaver county; hence the confusion.—Editor.]

Cobalt's silver production in 1915 was 23,730,839 oz., worth $11,742,463. Nine companies there produced over 1,000,000 oz. during the year. The Mining Corporation ranked next to Nipissing, with an output of 2,776,589 oz. from the Townsite mine and 1,566,206 oz. from Cobalt Lake. Seneca-Superior, which only recently took a place as a successful producer, ranked fourth or next to the Kerr Lake company. Temiskaming's output was 1,486,400 oz. exceeding La Rose or McKinley-Darragh-Savage. Dividends from the Cobalt mines for 1915 amounted to $4,441,948, making a total return to shareholders of $59,660,912.

Nickel-copper ore raised in Canada in 1915 was 1,325,973 tons. The Canadian Copper Co. smelted 865,169 tons and the Mond Nickel Co. 407,144 tons.

The Flotation Process—III: Patents

By T. A. Rickard

*THIS is the part of the subject of which we have heard the most; indeed, until recently the literature of the flotation process was closely identified with the records of patent litigation. That is why the scientific principles are as yet so little understood and the technology of the process has made such scanty progress. The aim of a patent specification is to disclose just enough to prove originality. In many cases this has been done to the apparent satisfaction of the Examiner of Patents without conveying all the facts essential to a clear understanding of the operations involved. The description given in a modern patent is cryptic; it is couched in a quasi-legal jargon that assists obfuscation. I refer to processes only, for the disputes over flotation patents have arisen over methods, not machines. The apparatus required had already been used in other branches of wet metallurgy, so that we have been spared one source of trouble, at least.

The litigation, which is now a serious obstacle to the free development of the process, has arisen largely from confusion of ideas as to the underlying causes of flotation. The patentees did not understand the phenomena with which they played. Those to whom they sold their patents knew even less. The interpretations of attorneys and judges have elucidated the law but confused the physics. No clear adjudication of rights is possible so long as claims and counter-claims are based on an ignorance of the rationale of the process.

As the flotation process of today is essentially that of making a mineral-buoying froth in modified water, it is not necessary for me to make further reference to the patents granted for the use of purely surface-tension effects. It would seem permissible also to omit further consideration of the bulk-oil methods, but, as a matter of fact, none of these operated without the aid of air, although the patentees were quite unaware of it, and it was from these bulk-oil methods that the frothing process was developed fortuitously.

The first patent for the use of oily substances and coal-tar products in the concentration of ores was that granted to William Haynes, an Englishman, in 1860; but this is now only of academic interest. Next comes the patent of Carrie J. Everson, dated August 24, 1886, the application having been filed on August 29, 1885.[1] The Everson patent refers to the selective action of oil for "metallic substances" and the increase caused in that selectiveness by the addition of acid. The pulp is stirred so as to bring "the mineral" in contact with the oil and acid, producing a "stiff mass." The use of "about a barrel of oil to the ton of ore" is mentioned, indicating a ratio of about 17%. Other statements indicate that she used as little as 5% of oil per ton of ore. The separation of the oiled mineral from the unoiled gangue is described thus: "In practice, the concentrate, after thorough agitation of the mass and detachment of the sand, will in this case be preferably removed by means of a constant overflow of water from a washing-out vessel, by which overflow the concentrate will be floated off." These last words constitute the only direct reference to the floating of the concentrate.

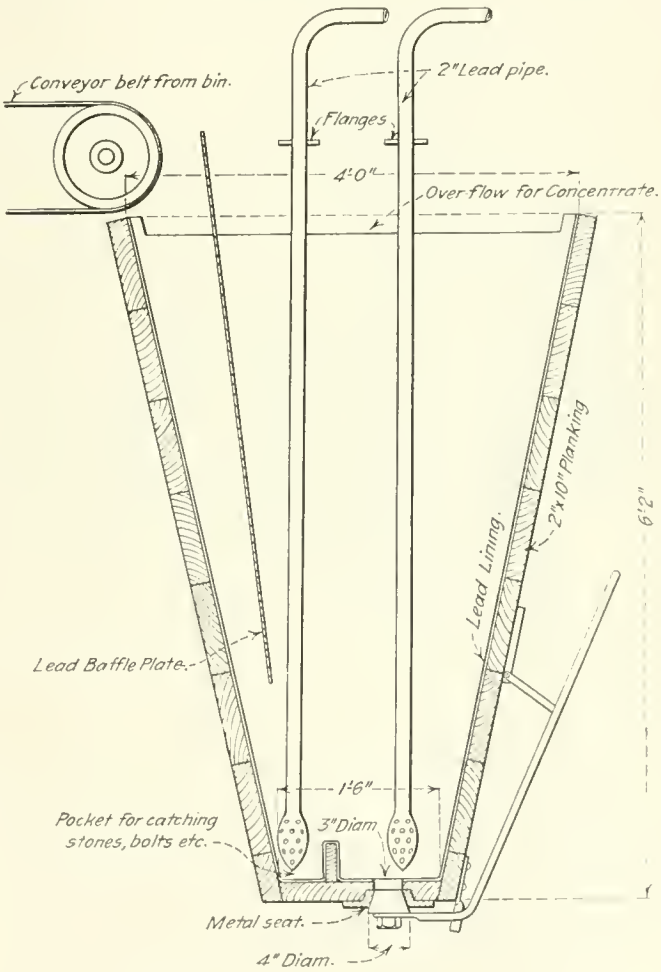

FIG. 10. THE POTTER APPARATUS.

A great deal more has been read into this patent than could ever have been in the mind of the patentee. It is difficult to read her description without cocking one eye at the present practice of flotation, whereby some of Mrs. Everson's phrasing is given a significance to which it had no possible claim 30 years ago. The proportion of oil used, even the maximum, would not suffice for the

*Part of a paper under the same title read before the March 1916 meeting of the Canadian Mining Institute.

[1]The date of application is the more important, as being the one from which priority of invention is measured.

operation she had in mind, namely, the floating of the heavy sulphides by direct aid of the buoyancy of oil. Her maximum proportion of oil represents a mere fraction of the quantity required for this operation. She disclosed no notion of the assistance to be obtained from air, in the form of bubbles, although, of course, this was her principal flotative agent. The process described by her is quite impracticable on a large scale, and it never was operated save in a crude experimental way. Nevertheless the exigencies of patent litigation have caused the opponents of Minerals Separation to idealize both Mrs. Everson and her metallurgical adventure, as they have also created a romantic story of the supposed epoch-making discovery. She is represented as a school-teacher, a Miss Everson, who as the sister of an assayer, washed some greasy ore-sacks and saw the sulphides floating on the contaminated water. Even the idea of agitation was suggested by the activity of her hands in the wash-tub. Therefore "it only required the customary acuteness of observation of the Western lady school-teacher to grasp the essential facts of sulphide flotation."[2] This is pretty, but not scientific. The "essential facts" are a bit too slippery to be grasped firmly even today. In thinking acid necessary, she was wrong. It is known now not to be an essential. Even the use of oil as a direct means of buoyancy has receded into the background; if she had understood the rationale of her own operations she would have known that it was not so much the selective adhesion of the oil to the mineral particles that gave her the requisite buoyancy as the greater selectiveness of the air bubbles made by agitation in water modified by the oil. Carrie Jane Everson had no idea of the frothing process. Her methods may have involved bubble-levitation, but she did not know it, and her description would not suggest it to anyone not versed in much later knowledge. The effort to feature this lady as the inventor of the frothing process cannot commend itself to an unprejudiced student of the subject.

It is interesting to add that the "Miss Everson" of the story was really a Mrs. Everson; the wife of a Chicago doctor; she was not a school-teacher; her brother was not an assayer; and there is no reason for regarding the story of the ore-sacks as anything more than the fiction of an irresponsible scribe.[3] Mrs. Everson died at San Anselmo, California, on November 3, 1914.[4]

Next comes the British patent of January 8, 1894, granted to George Robson,[5] an Englishman, who did his experimental work at the same place and on the same ores as the Elmore brothers, at the Glasdir mine, near Dolgelly, in Wales. He disclaimed "the use of acids or salts and also the method of washing away the gangue with water," effecting "the separation of the metallic matter by the mixture of oils alone." He does not specify the quantity of oil, but I am informed that it was in the ratio of 3:1, three tons of oil to one of ore. This was true bulk oil flotation and it proved an abject failure.

Then came Francis Edward Elmore, on April 10, 1899, duplicating his British patent of October 18, 1898. His method has been described already. It only remains to say that in so far as this method proved more practicable than that of Robson, the result was due to the fact that the Elmore brothers were capable engineers and therefore designed a more suitable plant. The patent ignored the use of air; the intention was not to emulsify the oil and not to aerate the pulp, but this theoretical condition was never fulfilled, as is clear from the fact that the flotative action was 150% more than that calculable from the difference of specific gravity between the oil and the water. On January 3, 1903, A. Stanley Elmore took out a British patent for an apparatus for excluding the air during the operation. He effected his purpose by sealing all the open vessels with a ring or surface of oil; from which it is evident that at that time he and his brother endeavored to base their method wholly on bulk-oil flotation.

In January 1902, Charles V. Potter, an Australian, obtained a British patent for the flotation of sulphides in a hot acid solution. He used a stirrer, and he claimed that the solution would "react on the soluble sulphides present to form bubbles of sulphuretted hydrogen on the ore particles and thereby raise them to the surface."[6]

In November of the same year, 1902, Guillaume D. Delprat, the manager of the Broken Hill Proprietary mine, applied for a similar patent, except that he used salt-cake instead of sulphuric acid. Litigation ensued, followed by a compromise, eliminating Potter. In later patents both Potter and Delprat introduced the use of oil, finding it beneficial.

In his first American patent, No. 735,071, filed on January 2, 1903, Delprat states that the process "depends upon the ore particles being attacked by the acid to form a gas. Each ore particle so attacked will have a bubble or bubbles of gas adhering to it, by means of which it will be floated and can be skimmed or floated off the solution." ("Ore particles" means blende and galena at Broken Hill.) Here is a pretty good recognition of bubble-levitation, only he supposed the sulphides, not the gangue, to be attacked by the acid. In another place he says specifically: "The sulphides in the ore are rapidly attacked by the acid and gas-bubbles formed on them, that quickly carry them to the surface." In this patent he claimed the use of nitric acid and a suitable nitrate, such as sodium nitrate, the latter being intended "to increase the specific gravity of the bath." What reaction was to follow between the sulphides and the dilute nitric acid is not clear. It has been recorded[7] that in the early days of the Potter-Delprat methods it was supposed that the acid liberated hydrogen sulphide from the sulphides, when sulphuric acid was used, without attacking the gangue. Those who first scouted this idea sug-

gested that carbon dioxide was generated by decomposition of a carbonate coating on the sulphides, due to weathering of the ore, arguing therefrom that it was necessary for the gas to be produced at the surface of the sulphide particles themselves. All of these explanations[8] are now on the scrap-heap of discarded theories.

These patents of Potter and Delprat have been labelled variously under 'acid-flotation' and 'surface tension'

methods. Delprat's apparatus does indeed suggest a process of the Bradford or Wood type, but, of course, both he and Potter depended for their results on the liberation of carbon-dioxide gas from the gangue, which, at Broken Hill, contains a large proportion of carbonates, notably calcite, siderite, and rhodocrosite. From any of these a hot sulphuric-acid solution would release the gas that promptly attached itself to the metallic surfaces of the galena and blende.

Meanwhile Alcide Froment, in Italy, had got hold of the bubble idea, which is the real basis of the flotation process as it is understood today. He invented his meth-

FIG. 12. THE CHIEF MINERALS SEPARATION PATENT.

od in 1901 and filed his claim for a British patent on June 9, 1902. This patent was duplicated in Italy, but *not* in the United States. The fact last mentioned is important. Froment claimed that his process was "a modification of what is known as the oil process of ore concentration," meaning that of Elmore, for the bulk-oil method had been tried at the Traversella mine, in Italy, where Froment was engaged as an engineer. His plan was to generate bubbles of gas by the reaction between sulphuric acid and the carbonates in the gangue, adding limestone when the ore did not contain enough carbonate. He argues that "if a gas of any kind is liberated in the mass, the bubbles of the gas become coated with an envelope of sulphides and thus rise readily to the surface of the liquid where they form a kind of metallic mag-

[8] In his book Mr. Hoover states (page 13, second edition) that Goyder & Laughton, in their patent of July 31, 1903, "were the first to disclose the principle governing Potter's and Delprat's acid-flotation process, namely, that the action of the acid on the ore generated gas-bubbles to which the sulphide particles attach themselves, and were floated to the surface." What they said was that "the physico-chemical action develops the formation of gas-bubbles adhering to particles of certain of the finely-divided minerals and causing such particles of certain minerals to rise to or near the surface of the solution." But this does not make it clear that the bubbles are obtained by the decomposition of the carbonates in the gangue; it is more nearly compatible with Delprat's idea that they were generated by the action of the acid on the sulphides themselves.

ma." It will be noted that he says "gas *of any kind*." As the children say, in a familiar game, he was "very warm" just then, for he had only to invoke the aid of air to have described the essential principle of the later phase of flotation. He also states that the sulphide particles when "moistened by a fatty substance" have a tendency "to unite as spherules and to float upon the surface of the water." His brief description closes with the statement that "the rapidity of the formation of the spherules and their ascension is in direct ratio to the quantity of gas produced in a given time." As to the oil, the only mention of quantity is made in describing a test tube experiment in which he uses "a thin layer of oil." This phrase has been variously interpreted, according to the exigencies of litigation, but it refers obviously to a minute proportion. In the directions given by him to the Minerals Separation people when they bought his patent rights on November 17, 1903, he specified 1% of mineral engine-oil for ore containing up to 5% of metal, 1½ of oil for ore containing 10%, and so on, up to ores containing 50% of metallic lead, which would require 3½% of oil. As oil flotation was understood at that time, this marked a great reduction in the proportion of oil. However, the more interesting point is Froment's failure to perceive the possibility of using air as the gas for making his bubbles. He depended upon chemical action to furnish him with the necessary gas. Nevertheless Froment deserves a high place in the roll of flotation pioneers, for he made an important step forward. He furnished the link between bulk-oil and air-froth flotation.

The next chapter in the story marks a retrogression. Under date of November 28, 1902, Arthur E. Cattermole obtained British patents No. 26,295 and 26,296, both of which were acquired by John Ballot and associates in December 1902, preparatory to the formation of the company—Minerals Separation, Ltd.—organized to exploit them. In August 1903 Cattermole revised and amplified his previous claims in British patent No. 18,589, which was duplicated in the United States under date of September 28, 1903, as No. 777,273. This last is the principal patent covering the so-called granulation process.

Cattermole prefaces his description by reference to the selectiveness of oil, when emulsified, for sulphide particles, such selective action being intensified by the acidulation of the water. He then proceeds to say that if the mixture be thoroughly agitated, there is a tendency for the metalliferous particles, now coated with oil, to adhere together, forming granules[9] that sink and are readily separated from the lighter gangue by an up-current of water. In his description of the operation he says that "the granules, with a certain amount of heavy sands, sink to the bottom and are discharged (see Fig. 11) through a pipe G^1 into the vessel A^7, while the lighter sands are carried away by the upward current and discharged through outlet G^2 to a light-sands tank J." In the drawing, A^1, A^2, A^3, A^4, A^5, and A^6 are mixing vessels, G and K are classifiers, E is a tank containing oil emulsion. He refers to the quantity of oil several times in vague terms, explaining, however, that it should be "insufficient to materially lessen the specific gravity of the metalliferous mineral particles." Finally, he specifies the proportion as "usually an amount of oil varying from 1% to 6% of the weight of metalliferous mineral matter present in the ore." This can be interpreted variously; if it refers to the sulphides to be concentrated, then an ore containing 20% blende would require from 0.8 to 1.2% of oil, equivalent to from 16 to 24 lb. oil per ton of ore. On the other hand a 2% chalcocite ore would need only 1.6 to 2.4 lb. of oil per ton of ore, which approaches the proportion now used.

This Cattermole process was the subject of lengthy experiment in the London laboratory of the Minerals Separation company, where all sorts of variations in temperature, acidification, oiling, and mixing were tried by Arthur H. Higgins under directions from H. L. Sulman and H. F. K. Picard. It was not until March 1905, that is, nearly 2½ years subsequent to the patenting of the Cattermole method, that it was found advisable to float the 'granules' rather than sink them, whereupon ensued "the startling discovery of the agitation-froth process" as W. H. Ballantyne has described it. A similar discovery was made contemporaneously at Broken Hill, but there, according to James Hebbard, it was not so "startling;" it was the result of strenuous efforts to make a workable process out of the impracticable method devised by Cattermole. See Fig. 12 and 14.

This 'discovery' led to Minerals Separation's basic patent U. S. No. 835,120, of May 29, 1905, which duplicated the British patent No. 7803 of April 12, 1905, taken out in the names of H. L. Sulman, H. F. K. Picard, and John Ballot. In this patent the aid of chemically-generated gas is discarded definitely, in favor of air-bubbles. This seems to me a matter of far greater importance than the reduction in the proportion of oil. The patentees say: "It is to be understood that the object of using acid in the pulp according to this invention is not to bring about the generation of gas for the purpose of flotation thereby, and the proportion of acid used is insufficient to cause chemical action in the metalliferous minerals present." This differentiates the method from those of Potter, Delprat, Froment, and De Bavay, the addition of acid being therefore presumably to assist the selective oiling of the sulphides. The patentees also state that "a large proportion of the mineral present rises to the surface in the form of a froth or scum which has derived its power of flotation mainly from the inclusion of air-bubbles introduced into the mass by the agitation, such bubbles or air-films adhering only to the mineral particles which are coated with oleic acid." The last clause had better have been omitted, for it is only conjecture, as to the truth of which there is room for plenty of doubt, but the clear description of air as the main agent of flotation is most important—far more important as regards the rationale of the process, than the diminution in the proportion of oil.

As to this, it is stated that if the proportion of oil

[9]The 'granules' may be contrasted with Froment's 'spherules.'

mentioned in the previous Cattermole patents "be considerably reduced—say to a fraction of 1% on the ore—granulation ceases to take place, and after vigorous agitation there is a tendency for a part of the oil-coated metalliferous matter to rise to the surface of the pulp in the form of a froth or scum." One per cent on the ore is equal to 20 lb. of oil per ton; a 'fraction' of 1% is anything between 20 and 0 pounds per ton. In enforcing the right to the collection of royalties, the Minerals

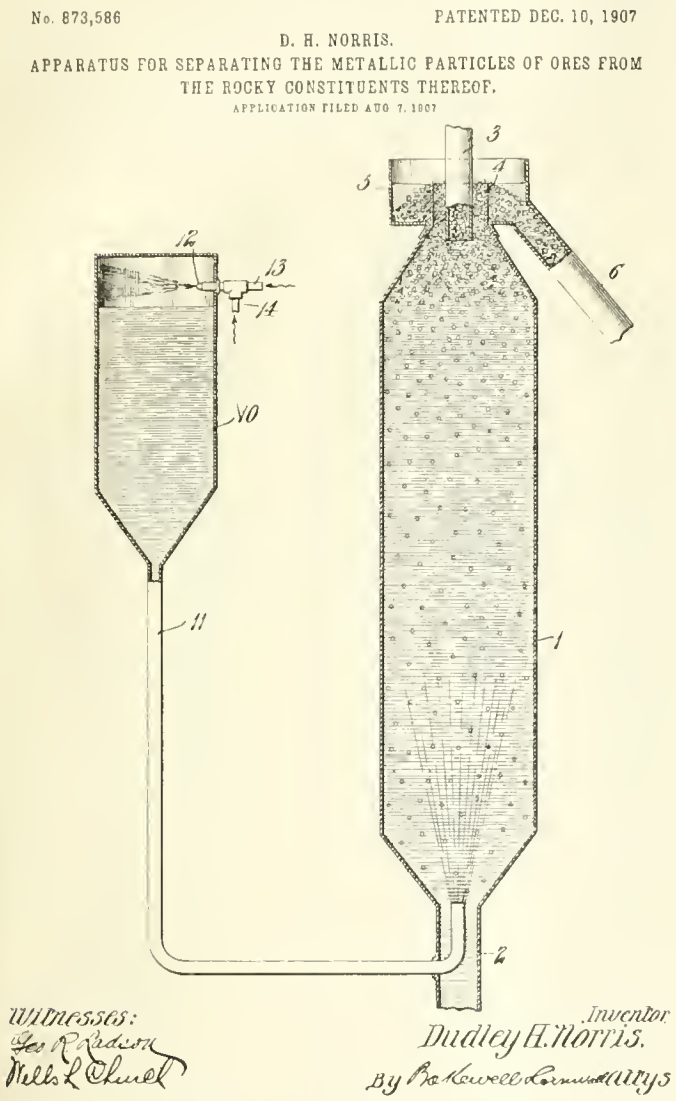

Fig. 13. THE NORRIS PATENT.

Between the Froment patent of 1902 and the Sulman-Picard-Ballot patent of 1905 comes the Kirby patent U. S. No. 809,959 of December 14, 1903, granted on January 16, 1906. This is interesting as specifying gentle agitation and the use of a gas, making it possible to use thin oils instead of the viscous oils of the prior (Elmore) art. The claim is made that 'the injection of gas, preferably air, into the mass, assists in the flotation of the hydrocarbon-coated particles." The mention of air, as

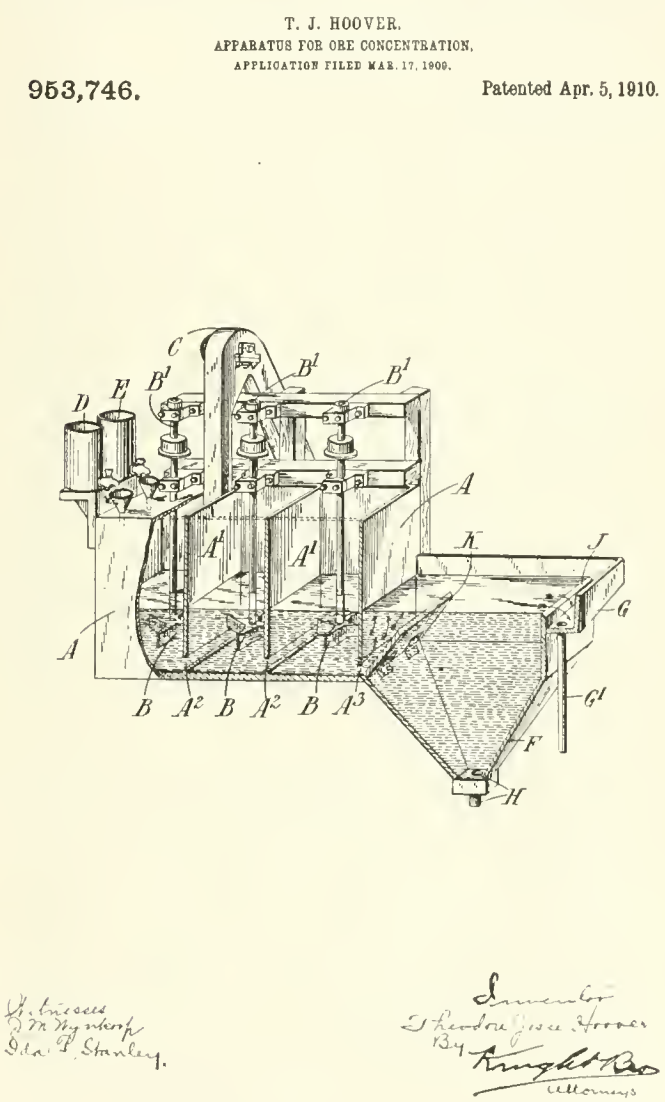

Fig. 14. THE HOOVER APPARATUS PATENT.

Separation company has rested its claim mainly on the reduction of oil, claiming that it produces a series of phenomena quite different from any of the other methods employing larger proportions of oil, and, concurrently, insisting that such superior effects as are produced by the use of the reduced quantity of oil are unobtainable when the larger proportions of oil are used. Thereupon, of course, it has been claimed, by those desiring to ignore the Minerals Separation basic patent, that neither the Cattermole nor the Froment methods demanded a quantity of oil notably larger, for the minima prescribed by these earlier inventors come under 20 lb. of oil per ton of ore. However, this matter is still *sub judice*, so it is best let alone for the present.

an assistant flotative agent, is more important than the reference to the kind of oil.

The actual part played by the oil has been misapprehended from the very first, the earlier investigators using not enough to produce bulk-oil flotation, while the later metallurgists have employed much more than was needed for bubble-levitation. The relative importance of the part played by air was persistently ignored until a late date and even then it was under-estimated. It is interesting to note that the two first patents in which air was specified as a gas suitable for flotative effects were those of F. E. Elmore and the firm of Sulman & Picard. Francis E. Elmore obtained a British patent for his vacuum-oil method under date of August 16, 1904, and

duplicated it in the United States as No. 826,411 of July 10, 1905. Sulman & Picard obtained a British patent for their perforated coil patent under date of September 22, 1903, duplicating it in the United States as No. 793,808 of October 5, 1903.

The Sulman & Picard patent just mentioned has been claimed by the Miami Copper Company as the one covering their operations with the Callow pneumatic cell.[10] In No. 793,808 the inventors "utilize the power which is possessed by films or bubbles of air or other gas of attaching themselves to solid particles moistened by oil or the like." They also state that they add oil "in quantity insufficient to raise the oiled mineral by virtue of the flotation power of the oil alone. A suitable gas is generated in or introduced into the mixture, such as air, carbonic-acid gas, sulphuretted hydrogen, or the like. For example, bicarbonates or carbonates, either soluble or insoluble in water (preferably the latter) or easily decomposable sulphides and the like may be used with acid solution." Thus they lessen the emphasis on air as the prime agent. The description also refers to the oiled metalliferous particles as "attaching to themselves, with a greater comparative strength than the gangue particles, the films or bubbles of gas which exist in the mass and are thus raised to the surface of the liquor by gaseous flotation." Yet we are told that the metallurgists who prepared this excellent description of the bubble-levitation method made "a startling discovery" of the frothing process eighteen months later. This U. S. patent 793,808 is more than a year junior to Froment's British patent, and contains an echo of it in the introductory announcement.

Elmore's vacuum-oil process marked another inadvertent step toward the recognition of air as the most important flotative agent. He utilizes the air naturally dissolved in water, releasing it for his purpose under a vacuum. The patent states that "under a vacuum or partial vacuum, air or gases dissolved in the milling water are liberated. These liberated gases may be augmented by the generation of gases in the pulp, or by introduction from an external source." Elmore invented a most ingenious machine for his purpose. In so far as he depended upon the air in a pulp that had undergone mixing with a quantity of oil relatively small (as compared with his bulk-oil method) he furnished a notable metallurgic sign-post, but it is necessary to remember that he mixed his crushed ore in acidulated water and that the acid would cause the generation of carbon-dioxide gas, thus explaining his reference to "air or gases."

The first inventor to break away from the use of either acid or oil and to make a clear claim for air as his sole flotative agent is Dudley H. Norris, in U. S. No. 864,856, under date of November 19, 1907, also in No. 873,586, of December 10, 1907. See Fig. 13. In his first patent he described a method for "introducing water containing air in solution into the lower end of an open-ended receptacle into which is introduced a flowing mixture of pulverized ore mixed with oil and water, thereby exposing said mixture to the continuous action of infinitesimally small nascent bubbles of air." He does not specify the use of acid and he distinctly says that he does not wish it to be understood that his method "is limited to the use of oil, as the method can be practised successfully without mixing oil with the pulverized ore and water." Incidentally, his method is worthy of friendly interest, for he has declared his intention to render the use of it free of tonnage royalty.

Having got rid of acid and oil, we have now reached the point where modified water mixed with the crushed ore in the presence of air suffices to form bubbles sufficiently lasting to buoy the metallic particles to the surface of the liquid.

[10]Note the sloping launder-like vessel used by both.

Metal Price Increase

The following table shows the great increase, in cents per pound, since the War commenced, according to *The American Metal Market*:

Metals	Before the War July 31, 1914	Now March 6, 1916	Increase, per cent
Lake copper	13.00	27.50	111
Electrolytic copper	12.75	27.50	116
Casting copper	12.62½	26.12½	107
Sheet-copper	18.50	34.00	84
Tin	33.00	48.50	47
Lead	3.72½	6.60	77
Spelter	4.85	19.25	297
Aluminum	17.25	63.00	265
Antimony	5.50	45.00	718
Copper wire	14.25	29.25	105
High-sheet brass	13.87½	40.00	188
Sheet-zinc	7.00	25.00	257
Iron and steel products			
Bars	1.15	2.25	96
Plates	1.15	2.35	104
Shapes	1.15	2.25	96
Pipe (⅜ to 3-in.)	1.95	2.55	31
Wire (nails)	1.55	2.40	55
Sheets (28 gauge)	1.80	2.60	44

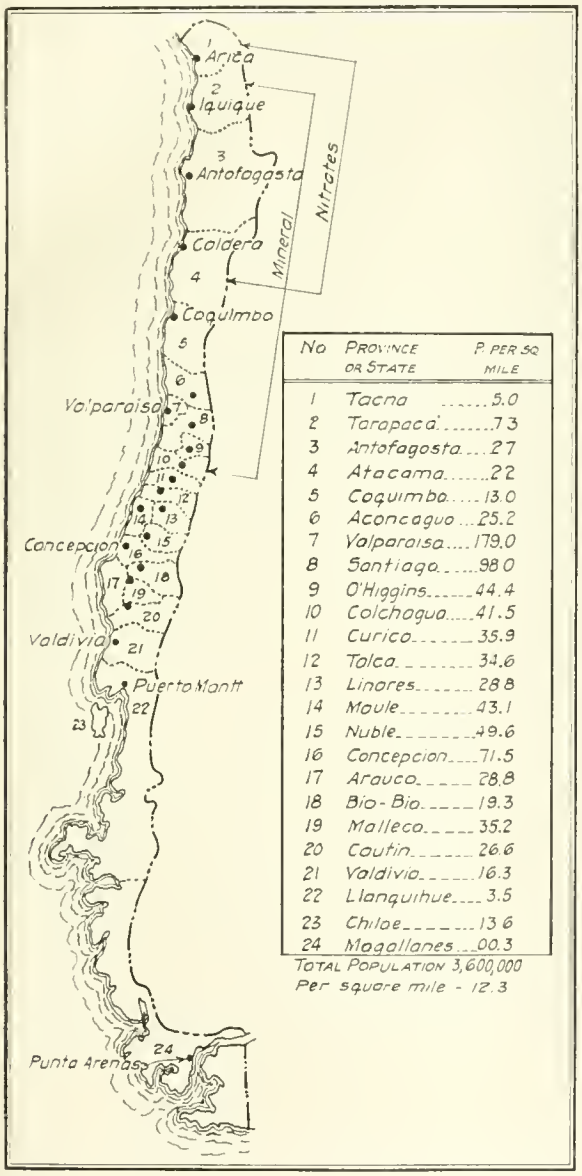
No. 2 foundry, Southern, Cincinnati	13.25	17.90	36

MINERAL PRODUCTION OF QUEBEC in 1915 was valued at $10,796,348, against $11,732,783 in the previous year. The falling-off was mostly in asbestos, which declined from 114,115 tons worth $3,544,302 to $2,895,935. Structural materials declined considerably. Chromite increased from $1210 to $221,287, the value of 14,076 tons, according to the superintendent of mines, Theo. C. Denis. Copper and sulphur ore rose over $200,000, and magnesite more than $135,000.

The Mineral Industry of Chile

By Lester W. Strauss

THE revival from the disturbed economic conditions, as the result of the 'Great War,' has had its effects in Chile, whose predominating revenue is due to the export tax on nitrate. This tax amounts to 80% of the total custom duties of the country and approximately



MAP OF CHILE.

The Braden mine is in the province of O'Higgins. The Chuquicamata mine is in the province of Antofagasta.

50% of the total Government income. The notable progress in 1915 has been the increase in production of nitrate and copper, now both handicapped by the scarcity of transport facilities for shipments abroad. The increased output of copper is from the Braden Copper Co., Chile Copper Co., and various local smelters. There appears to be another extensive low-grade copper property to be added to the type of deposit exploited at the Braden and Chuquicamata mines, as the result of the exploratory work of the Andes Exploration Co. The property in question, the Potrerillos, is at 13,000 ft. altitude; it is reached from the port of Chañaral, in Atacama, and has been under development for two years by the Anaconda Copper Co. Otherwise no new properties of magnitude have been developed, but several 'possibilities' are under option to American interests.

The nitrate industry, which was hard hit, as a result of the world crisis, at a time when production was attaining proportions commensurate with the most economical results, has made a good recovery from the depression, only to be confronted by a dearth of shipping facilities and excessive freight-rates. The present situation tends toward curtailment of production to prevent an accumulation of stocks, as a further decline of prices would compel the shut-down of many plants and a reversion to conditions that existed when the War broke out, namely, an exodus of labor. In August 1914 an arrangement was effected by the Government to aid producers by advances on the nitrate delivered at the various ports; up to date over 80% of the funds advanced have been returned with interest. On December 31, 1914, only 38 plants were in operation as compared with 127 at the end of 1913, and 115 at the end of 1915. The following figures (in quintals of 46 kilo. = 101.44 lb.) indicate the effect of the War on the industry and the recovery that has been made since August 1914:

	1913	1914	1915
Production, Jan.-July	35,388,811	37,862,106	15,610,634
Exported, " "	30,481,463	30,538,756	22,878,761
Production, Aug.-Dec.	24,877,584	15,649,115	22,557,869
Exported, " "	29,047,647	9,611,717	21,104,899
Total production	60,266,395	53,511,221	38,168,503
" exported	59,529,110	40,150,473	43,983,660
Production, December 1915			5,538,151
Exported, " "			5,174,087
" January 1916 (est.)			6,200,000
Stocks, December 31 (est.)	10,396,000	23,556,000	17,099,000
Exported to United States:			
January-July	9,398,404	8,026,675	10,950,930
August-December	4,314,379	3,642,850	7,474,941
Export, Jan.-Dec.	13,712,783	11,669,525	18,425,871

The United States is the largest purchaser since Germany has been eliminated from the market.

The rising prices of coal and fuel-oil, in particular, as well as other supplies, has resulted in higher operating costs, and the scarcity of shipping has placed the nitrate industry in a trying position. The sudden withdrawal of the Panama Canal as a shorter route, due to the big slides in October, made itself appreciated in the decline of the price of nitrate; numerous ships were tied up at

Colon and Balboa until it was definitely known that no traffic was possible. The loss by demurrage was accentuated by the additional cost in the long trip through the Straits of Magellan. The following figures give some idea of the fluctuations in the price of nitrate (duty paid alongside) per 46 kilo and freight rates per 2240 lb., in U. S. currency, during the past three years:

	1913	1914	1915
Price of 95% nitrate, prompt delivery quotation on December 31	$1.92	$1.38	$1.61
Freight rates (steamer carriers) quotations on December 31	7.20	20.40	30.00

Beginning in January 1915, the price rose steadily, reaching $2.28 in October; but the closing of the Panama Canal and the freight-famine caused a decline to present prices. Many of the plants are shipping double-refined nitrate above 96% $NaNO_3$, which averages 8 cents more per 46 kilo., and affords a slightly higher marginal profit. His Excellency Sr. Luis Sanfuentes, who became President of Chile in December 1915, has taken much interest in arriving at a practical means of lifting the accumulating nitrate stocks. The endeavor to utilize the twenty-odd German steamers—disregarding the sailing vessels—that are lying in various Chilean ports must first meet with some approval from the British and German governments. The latter is doubtless not inclined to sell or risk its merchant ships, which will be needed once peace is attained. Recently Gibbs & Co. (an English firm) bought a small steamer (3000 tons capacity) from the Compañia Sud Americana de Vapores, a Chilean company, the sale of which caused much local discussion. The British government is subsidizing numerous steamers of the Pacific Steam Navigation Co.'s fleet that have been plying on the West Coast, but many of these ships will continue in the service as heretofore.

Through the efforts of Sr. Agustin Edwards, Chilean Minister to England, arrangements are being brought to a successful issue whereby the British government will effect lower freight-rates. This circumstance should reflect in higher prices for nitrate on the Coast. There appears to be a general tendency on the part of the producer not to sell ahead. It behooves the Chilean government to help exportation by reason of the increased revenue from the tax imposed.

The Chilean government has offered two of its transports (total 15,000 tons capacity) as nitrate-carriers to the United States, terms being on a ton-rate. Three bids were made: the bid tendered by Gibbs & Co. has been accepted, being 117.5 shillings ($28.20) per long ton by the Straits of Magellan, or 102.5-107.5s. ($24.60 to $25.80) by the Panama Canal, the charter being granted for two trips, the return cargo to be optional to the Government. The lower rate by the Canal is to a port on the Gulf of Mexico; the higher rate to a port on the Atlantic Coast.

The Dupont Nitrate Co., the one company owned by and operating with capital from the United States, produced about 530,000 quintals of 97%, or double-refined, nitrate, being the output from their Delaware and Carolina properties; another property was purchased early in the year. The company is also an extensive buyer of nitrate.

There continues to be considerable Governmental discussion as to effecting an organization that would eliminate the speculative movements in the price of the nitrate, which fluctuations do not benefit the producers but disgust the consumer; this elimination of the middleman will lead to a better appreciation of nitrate through the control of, and steadiness of, the selling prices.

Some experimenting has been done at various plants toward increasing extraction; the Hardinge mill and Butters filter have given encouraging results at one plant. Numerous schemes have been suggested.

Despite the part success in Germany of the production and application of ammonium sulphate (at a probable higher cost than Chilean nitrate), that country will undoubtedly be again in the market, once peace is assured, which is evidenced in the purchasing of nitrate ground by German interests.

The bright spots are in copper and iron mining. The production of copper has probably attained the high mark of 1876 (52,308 metric tons). The iron mines continue to be in the development and construction stage. It is an interesting fact that capital from the United States is responsible for the advances made in the extensive developments of these metals in Chile. The total copper exported from Chile during 1915 as compared with 1914 is given below, also the copper produced during the respective years. These figures cover bar copper, copper matte, and minerals.

	1914 Metric tons	1915 Metric tons
Exported	40,444	45,022
Produced	44,665	52,000*

*Estimated.

The total copper production of Chile from 1811 to 1915, inclusive, has been 2,387,000 tons. The 1915 production places the country as the third in rank of the world's copper producers. It seems likely that operations for 1916 may result in exceeding Japan's production (68,072 tons for 1914) and entry to second place. Nearly 50% of the 1915 production is from properties (Braden and Chile Copper companies) controlled by capital from the United States.

The largest copper producer, as yet, is the Braden Copper Co., being responsible for 30% of the country's total output. The following figures indicate the scale of operations during 1914 and 1915:

	1914 Short tons	1915 Short tons
Ore hauled from mine	894,491	1,198,167
Ore milled	900,299	1,195,858
Concentrate produced	84,783	104,847
Concentrate smelted	87,925	102,868
Blister produced	14,152	17,647

"The adoption of nodulizers in December 1914 to dry the flotation concentrate and reduce the sulphur content (from 28 to 18%) has given excellent results. The concentrate agglomerates into masses up to a foot in diameter. Four nodulizing-kilns will be in use; three capable of handling 215 tons of concentrate, resulting in 180

tons of nodules, per 24 hours are actually in service. The kilns are oil-fired; the gases pass through a dust-chamber and out to a stack. Nodulizing has resulted in better smelting work and lower costs, the latter due to less coke consumption in the blast-furnaces. Some of the concentrate (50 tons per day) is sintered; the sulphur content is reduced from 28 to 12%. Raw concentrate is also smelted, about 85 tons per day."* The acid plant has proved itself a success, but leaching of the concentrate has not been started on anything but an experimental scale. The acid production at present is in excess of requirements for the Minerals Separation process. It has been unofficially stated that the mill will be increased to 6000 tons daily capacity and such improvements effected as to increase the monthly output to 2500 short tons of copper; during the last quarter of 1915 the monthly output was at the rate of 1800 tons of metal.

The operations of the Chile Copper Co. at Chuquicamata began in May and have been undergoing the usual experiences of a new treatment plant operating under novel conditions. Since August the monthly output has been about 1500 short tons of ingot copper. The deposit is stated to contain over 400,000,000 tons of 2% copper ore, which makes it the premier property of the world as regards tonnage of commercial mineral.

All the smelters in the country, with the exception of the Braden plant, are custom plants. These are now increasing their outputs, aided by the high freights on shipments of ore to the United States and England. Freight on bar copper to the United States is £5 per long ton; minerals pay from £4 to £5 per ton, in sacks. Contracts for large tonnage are said to exist at lower figures. There are four active smelters producing bar copper, as follows, in metric tons of fine copper.

	1914	1915
Gatico	2388	3000
Catemu	3537	3500
Natalgua	2481	3500
Lota	3503	3948*

*Includes purchased matte.

The first and last are situated on the coast (the Lota smelter is close to the coal mines it controls); the other two are inside from Valparaiso. Catemu and Naltagua are planning to smelt with reverberatories, using native coal, probably to be pulverized, in view of the high price of coke.

The most important matte-producing smelters are as follows, the production being given in metric tons of fine copper.

	1914	1915
Chañaral	1499	2500
Caldera	3004	3400
Carrizal	969	1000*
Panucillo	2482	2700

*Estimated.

With the exception of Carrizal, the other plants produce matte varying from 46 to 50% copper; Carrizal matte is under 40% copper.

*This and the following data have been extracted from the November issue of the *Teniente Topics*, published by the staff of the Braden Copper Company.

Other smelters exist, but they have been either in intermittent operation or are small producers.

Coke costs 85 to 100 shillings ($20.40 to $24) per long ton, aboard ship, as against 35 to 40s. ($8.40 to $9.60) in normal times.

Of the smelters mentioned above, the year 1916 will show increased production at the following:

The old Gatico furnace, 140 by 38, has been lengthened to 213 by 38, which, it is stated, will increase the monthly tonnage treated from 3000 to 5000 tons, resulting in an output of 400 metric tons of copper per month; new converter-stands, blowing-engine, and accessory plant have been installed. The mines controlled have been undergoing vigorous development and preparation.

The directors of the Sociedad Industrial de Atacama are planning to convert the matte produced at Caldera, at present about 600 tons per month.

Improvements under consideration are anticipated to raise the individual yearly output at Catemu and Naltagua to 5000 metric tons of copper.

The Guayacan smelter, near Coquimbo, has been idle owing to the re-organization now under way. The smelter of the Compañia Minera de Calama, near Calama, has been operating spasmodically and is now shut down during a period of restoration. There are several properties that treat their mineral in small furnaces and sell the resultant matte to local smelters making bar copper.

The mines that have no smelting plants and formerly shipped their products abroad are hard hit by the high cost of freight, barring the few which have had long-time freight contracts. The less fortunate companies are shipping to local smelters. The principal districts from which ores are being shipped are Tocopilla, Collahuasi, Chuquicamata, Copiapó, and Los Condes.

Silver mining continues to be a declining industry; the famous Huantajaya and Santa Rosa districts near Iquique and the Compañia de Minas de Beneficiadora de Taltal, inside from the port of Taltal, are responsible for more than 65% of the total silver produced exclusive of that contained in blister copper, matte, and mineral exported. Figures for 1915 are not available at present, the following data are of interest:

	1913	1914
	Oz.	Oz.
Total silver of commercial value	940,000	882,000
Total silver reported	1,272,000	1,176,000

Several properties are under development in the once famous Chañarcillos district.

Gold mining is an unimportant industry, in which vein-mining contributes less than placer work.

	1913	1914
	Oz.	Oz.
Total gold of commercial value	14,540	10,670
Total gold reported	22,340	24,000

Less than 3% was locked up in copper products. No mills of note are in operation.

Lead mining is of interest because of the gold and silver in the lead ores. In 1913, 74.5 metric tons of lead was exported, as compared with 68.8 tons in 1914. One

zinc property produced in a small way, but the War cut off its market, as the sorted product was shipped to Germany. In 1913, 50 metric tons of zinc mineral was exported, compared with 8 tons in 1914.

The values of the principal metallic and non-metallic minerals produced during 1913 and 1914 are as follows (data for 1915 not available yet):

	1913		1914	
	Quantity	Value	Quantity	Value
Gold	1,116,929 grams	$275,200	1,016,896 grams	$200,000
Silver	39,563,564 "	502,900	36,581,083 "	130,800
Copper	42,263 tons	11,413,700	44,665 tons	11,318,900
Iron	14,100 "	101,520	63,505 "	157,240
Coal	1,283,150 "	8,778,800	1,086,946 "	7,829,000
Nitrate	2,772,254 "	114,771,300	2,463,356 "	101,982,940
Iodine	436,971 kilo.	1,818,400	488,952 kilo.	2,068,270
Borax	50,225 tons	2,531,360	31,907 tons	1,608,110
Sulphur	6,647 "	287,150	10,008 "	132,350
		$140,510,330		$126,327,610
Total value including items not mentioned above		$141,661,517		$127,332,972

The coal mining industry, confined to the southern part of Chile, is responsible for 1,086,946 metric tons in 1914; the coal is semi-bituminous, fairly high in ash and not of high steam-raising quality. It is used principally on coast steamers and the Chilean State Railways. The excess demand for coal has created a market for imported coal, chiefly English and Australian (the tonnage from the United States is small), exceeding 1,000,000 tons per year. The War has affected this importation, causing a scarcity and high prices, primarily due to lack of ships; this condition has been accentuated by the temporary closing of the Panama Canal. Local coal is selling at present for 30 shillings ($7.20) per ton on board ship at the ports of the principal mines. The price in normal times is 22s. ($5.28) per ton. Australian and English coal is up to 80s. ($19.20) per long ton, and scarce at that price, as against 29 to 32s. ($6.96 to $7.68) in normal times. These high prices would appear to be an inducement to ship coal from the United States if steamers were available and the passage through the Panama Canal open to large carriers. The development of this business would create a return freight for nitrate. The scarcity of high quality steaming (bituminous) coal is not likely to be relieved during the War.

Petroleum has also risen in price, California crude oil being quoted at 56 shillings ($13.44) per metric ton on the coast, while 30s. ($7.20) prevailed in normal times.

Of more than passing interest is the establishment of the National City Bank of New York in Chile. The Government has granted the necessary authorization so that the opening of the head office and its branches are to follow soon; the capital of the branch is to be $1,000,000. The advent of 'dollar credit' should do much to foster commercial relations between Chile and the United States.

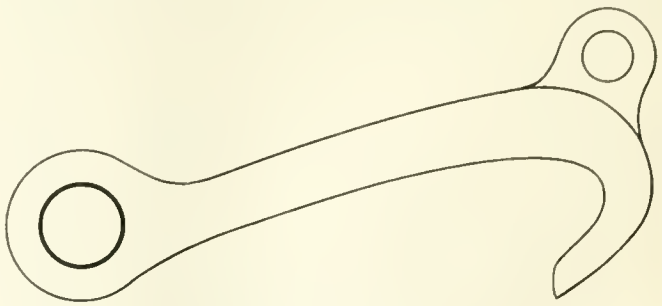
During 1915 there have been discussions at various times as to imposing export duties on copper minerals and products, also on iron ores. It is not likely that such a step will be taken. At present the following export taxes exist:

Nitrate	$0.56 per	101.4 lb.	(46 kilo.)
Iodine	0.46 "	2.2 "	(1 ")
Borax	2.38 "	2204.6 "	(metric ton)

The year 1913 represents the highest production as yet attained; in 1903 the total value was $64,356,541.

Coupling-Hook for Electric Locomotive

The accompanying coupling-hook is used in disconnecting a train of mine-cars from the electric haulage locomotive when the train is connected to the end of the motor opposite to that at which the motorman's seat is situated. To effect this disconnection, the motorman pulls a cord that is attached to the hook of the offset eye—the other end of the hook is attached to the chain coupling of the motor. This causes the hook to turn in



IMPROVED COUPLING-HOOK.

the connecting-chain link and to disengage from it. The use of this hook makes it unnecessary for a man to get his hands between the motor and the cars, and in some cases it saves the labor of one man on the train. The hook is particularly satisfactory for the uncoupling of a train when it is in motion, as the former way of accomplishing this by hand was dangerous. The hook is used in the Leonard mine of the Anaconda Copper Mining Co. and was the invention of John R. Jones, a motorman. The excerpt is from *The Anode*.

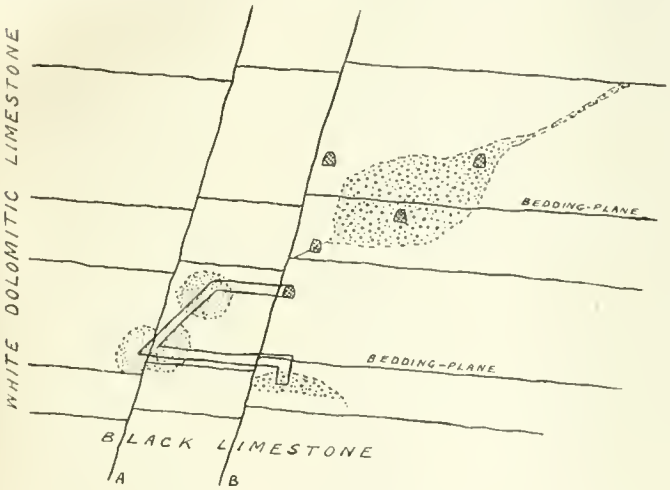
THE Matahambra copper mine in Pinas Del Rio, Cuba, is shipping 6000 tons of high-grade copper ore per month to the United States. This will be increased to 9000 tons in a few months. The company is about to erect a concentration plant.

Platinum at the Boss Mine, Goodsprings, Nevada

By Frank A. Crampton*

IN September, 1914, the announcement was made of a discovery of ore of the platinum group in the Boss mine at Goodsprings, Nevada. For one reason or another very little that is worth while, although much in quantity, has been written about the mine, and it is the purpose of this paper to supply first-hand data hitherto unavailable.

This mine was located in 1885 as a copper claim, and was worked in a desultory manner until 1914, when gold was found. In September of that year, in an assay of a sample of shipping ore, platinum was noted by H. K. Riddal, assayer for the owners. This, in itself,



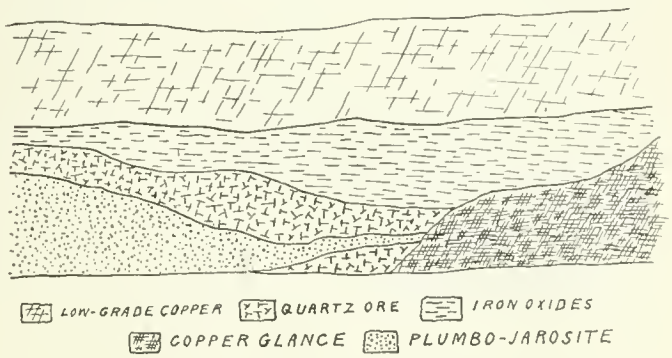
SECTION OF THE BOSS MINE.

does not appear out of the ordinary, but when it is considered that platinum was known to at least two engineers eight years prior to this fact, the fact seems worthy of comment. The explanation is simple. The owners were not sampling and assaying frequently, if at all.

The mine is situated in the Yellow Pine mining district of Clark county, Nevada, 12 miles west of Jean and 8 miles south-west of Goodsprings. The property lies on the west slope of the Spring range, the general geology of which has been described by J. E. Spurr in Bulletin No. 208 of the U. S. Geological Survey. The formation is distinctly sedimentary, consisting mainly of limestone, sandstone, and occasionally beds of conglomerate or shale. The upper rocks of the range nearest the mine are dolomites of Middle Carboniferous age. Between these beds distinct layers of cherty and dolomitic limestone occur. Many fossils are found, principally crinoids, though I have found what was apparently a trilobite. These fossils are peculiar to the chert and shale, but there are fossils in the upper dolomites. Underneath is a blue, fine-grained, crystalline limestone of Middle Carboniferous or Pennsylvanian age.

The beds are badly faulted and broken by a complex system of folding. The folding is due to a number of quartz-monzonite intrusions and to a general uplift caused partly by an extinct volcano, the Little Devil peak, eight miles south-west of the Boss.

It is chiefly in the dolomitic limestone that the ore is found, this rock being easier of replacement by mineralizing solutions, but the shaly and cherty dolomitic limestones are also somewhat mineralized. On the bedding contacts of the dolomites and the dolomitic shales and cherts a distinct replacement has occurred at places where the solutions have been restricted in their flow. So far as mine development shows, there is no ore in, or below, the beds of darker limestone, though in some of



CROSS-SECTION OF BOSS OREBODY.

them ore exists on the contacts of these beds. This fact is notable, particularly where the white and blue limestones form contacts with quartz-monzonite porphyry, the matrix in such cases being usually the porphyry itself, and so differs from the other mines in there being no appreciable replacement of limestone.

The mineralization apparently was a sequel to a minor but general settling of the country, yet prior to any marked upheaval; consequently the bedding-planes at the time of the mineralization, though locally faulted and shaken, were normally in a horizontal position. The mineralizing solutions followed the bedding-planes, as they afforded more easy passage. These replaced the dolomite. In several instances the solutions have left the bedding to follow more open fractures. As a rule the replacement along the bedding is of minor importance. The chief factor in any replacement is a tightening in the channel of flow. This system of mineralization is confusing, and often leads to the erroneous idea that the ore has been confined to fractures and faults, whereas such is not the case.

Along the mineralized beds the thickness of ore may

*Superintendent, Platinum Gold Mining Company.

vary from a thin seam to many feet, depending upon the character of the limestone through which it passes, its susceptibility to replacement, and its porosity or shattered condition. There is a distinct system of replacement, but owing to tightening of the beds and the more open faults, to the more open beds and the tighter bedding-faults, there is apparently no conformity. The mineralizing solutions, replaced in the beds above, dropped to the beds below through bedding-faults, there to follow a bedding-plane and again to drop. The result resembles step-faulting.

The orebodies are similar in so far as the mineralization took place in practically the same manner and under like conditions. The mineralizations do not seem to have had the same source; at least, they happened at periods widely separated. The solutions apparently have followed bedding-planes, mineralizing them to a slight extent; when they came to open beds, they followed these downward; and as the dolomitic or shaly limestones were reached, they made large replacements, and continued downward and horizontally along and through the other beds, to repeat the mineralization again under favorable conditions. It is at these points, either where the solutions were forced to seek a bedding-fault or at the foot of the fault where they had again to follow a bedding-plane, that a marked replacement is visible. It does not necessarily follow that there would be a replacement in the bedding-faults or near them; many small replacements have occurred in minor bedding-faults, but none of any consequence has been noted. Some large replacements have been found in the bedding-planes, but as a rule any replacement along a bedding-plane is of minor importance. The chief factor in any of the replacements is a tightening in the channel of flow.

There are three definite systems of faulting. The most important has a course of N 55° E; the second approximately N 5 W, and a third series N 25° E. The great fault is easily traced for several miles and steps on the north-west side, a distance not determined, through 12 or 15 ft. The lateral thrust of this is normal and 10 ft. to the north. The second series appears at frequent intervals and displaces the orebody at each intersection, vertically about 5 ft. and laterally 8 ft. These faults are irregular in dip.

It is important to note here that the minor faults apparently played no part in the mineralization; that they were subsequent to the mineralization is proved conclusively by the fact that brecciated ore is occasionally found in the fault-zone, and in some instances many feet from known ore. The faults have played a minor part, however, in a secondary replacement and re-deposition of metals, as some kidneys of the oxides of iron and copper occur close-by. None of these are of any consequence or of commercial size or value, the largest does not exceed a few cubic feet, although some of the kidneys assay high.

The fault system is important, for two miles distant on the great fault is the Oro Amigo, a prospect in which ore carrying platinum has been found. Still nearer the Boss and about a mile away is another, the Betty Brown, which shows traces of these metals. That two other prospects along the same fault show platinum ore is significant, but the connection is not clear.

At the base of the mountain below the Boss occurs an intrusion of quartz monzonite porphyry. This forms a sheet between two beds of the darker lime-stone, and apparently does not penetrate to the upper beds of lighter dolomite. This porphyry outcrops at several points along the line of the great fault, but always to the north, while the ore lies south. The fault, no doubt, is due directly to some intrusion, and it is logical to assume that the one from which the outcropping sheets of quartz-monzonite porphyry originated was the cause.

Generally speaking, the mineralized body of the upper level is highly oxidized and constitutes a zone of low-grade copper carbonate. Underlying this in the more shallow workings is a core of quartzose material with a soft filling of gray or yellow powdery material. This is described by Adolph Knopf in Bulletin 620A, of the U. S. Geological Survey, and determined by analysis, as bismutho-plumbo-jarosite. Merging into the gray quartz as depth is attained are limonite, hematite, and magnetite. These form small seams at the outer extremity of the ore-zone; in depth they gain magnitude, the gray quartzose bismutho-plumbo-jarosite in turn becoming less. As this disappears, chalcocite takes its place. The chalcocite ore increases in proportion when iron oxides disappear. The upper capping of low-grade copper appears to be uniform in size while the other ores vary as described. It is worthy of note that cross-sections at all points in the main orebody, though the composition of it may differ, will appear nearly uniform. There is no large mineralized zone exposed on the second level. The mineralized masses below the second level and on the third have been so thoroughly leached that they cannot be considered as ore. They consist of limonite, magnetite, and hematite, with a thin casing of malachite. Throughout this mineralized zone the platinum and gold are present in traces only, while copper, except in isolated kidneys is less than 2%. This is substantiated by the occurrence of chalcocite ore beneath this zone and 40 ft. south. This ore contains platinum to less than 0.05 ounces, and gold of the average gold content, but is comparatively high in silver. On the chalcocite, much as placer gold in creek-beds, is a seam rich in platinum, but in the bulk-ore there is none. This is important, for it suggests re-precipitation. Assays show that platinum and palladium are concentrated with the high-grade copper ore on the upper levels. That the platinum has not migrated to the levels below would indicate a leaching under different chemical conditions and at different periods of time. The upper part of the mineralized body usually carries but little gold and platinum, while the base of the deposit holds the high-grade seams. Contrary to general belief, the Boss is not a high-grade mine, and with the exception of a single pocket that contained a few hundred pounds of very rich stuff, the occurrence

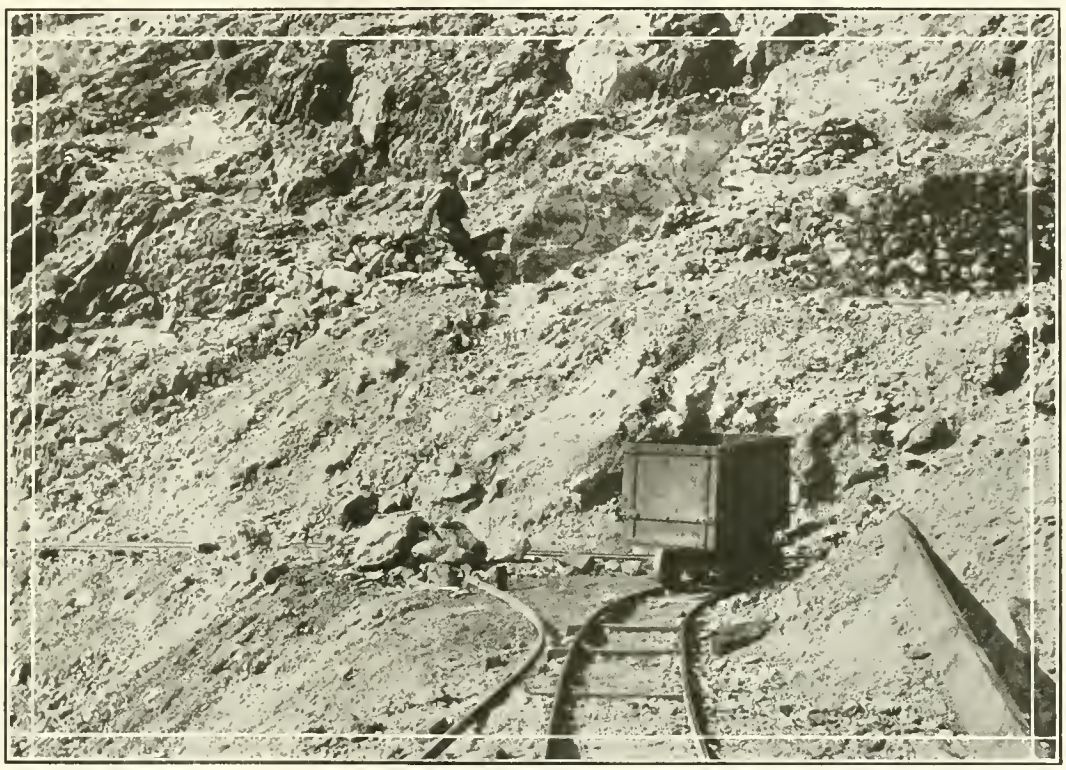
of the high-grade plumbo-jarosite is confined to a seam rarely as much as an inch thick.

Two ore-shoots are defined. The copper one, generally speaking, caps the gold-platinum pipe. The upper zone is much leached, the copper having been precipitated in the form of malachite on the limonite that forms the upper portion of the higher-grade quartzose pipe. As depth is attained, the leaching is less apparent, and the copper forms a mass containing more chalcocite, with some native copper. The leached portions of this mass assay 6% copper, 0.12 oz. gold, and 0.04 oz. platinum per ton, while the enriched and less leached portions show copper 17%, gold 1.2 oz., platinum metals 1.72 oz. This would seem to indicate that the copper minerals are responsible for the presence of platinum. Possibly the leaching and enrichment of the copper ore caused a segregation of the platinum metals, for in many samples the gold is negligible and the platinum high. In one instance a sample showed 0.32 oz. gold and 58 oz. platinum metals. At the extreme east of the ore-zone some chalcocite was found that assayed only 0.04 oz. platinum.

The fact that in different sections the same types of ore vary greatly in platinum content is confusing. A possible explanation is offered by the fact that as depth is attained the valuable contents become less segregated and more uniform, owing to the mineralized zone becoming more compact and the possibilities for leaching less throughout the mass. The quartzose material forming the core or pipe contains the greatest amount of platinum. This pipe is of a grayish vesicular quartz in the centre of which is the plumbo-jarosite, a soft gray to yellow or green powdery material crumbling to the touch and with the soapy feeling of silver chloride.

The vesicular quartz forms the greater portion of the orebody, but assays the lowest: gold 1.40 oz.; platinum 0.84 oz.; or about $60 per ton. The enrichment throughout is uniform and seems to indicate a definite mineralization. The plumbo-jarosite is erratic, varying between $10 and $200 per ton; this does not include the high-grade seams that form a mere fraction of the ore. On account of their extreme thinness, true samples are nearly impossible, but the ore varies between $6000 and $48,000 per ton, according to the width. The thinner the seam the higher the assay. This is by far the most important segregation of metals in the mine. The quartz has apparently held its grade consistently while the softer plumbo-jarosite underwent a re-deposition and a decided segregation.

It is probable that leaching and chemical action are responsible for the ore, and that the deposit was principally of copper. The preponderance of platinum in chalcocite and plumbo-jarosite, or in the core of quartzose material, leads to the conclusion that during the migration the copper and platinum metals made enrichments and (note Knopf) consequent segregations. The chalcocite deposition occurs in the extreme innermost working and at the maximum depth. The plumbo-jarosite ore occupies the same relative position in the mineralized body that the chalcocite does at greater depth. This, in turn, would indicate that the ore was at one time chalcocite but an additional leaching and chemical action carried away the copper, leaving the plumbo-jarosite as residue. This theory is borne out by the occurrence of chalcocite on the third level, where it carries little or no platinum except in a superficial seam. That the mineralized bodies on the third level carry little or no platinum metals would indicate that the segregation of the rare metals is in the ore-zones above, and most decidedly in those nearest the surface.



ENTRY AT No. 1 LEVEL, BOSS MINE.

The smooth face of rock 10 feet above the car marks the face of the big fault.

The occurrence of platinum metals in ore, particularly in ore of copper or nickel is not unusual, but no ore hitherto known has contained the metals in high enough proportion to make it commercially valuable. The Boss, in this respect, stands alone. Platinum is known in the nickel ores of Sudbury, Ontario, and at the New Rambler mine in Wyoming, at the latter, however, the rare metals do not appear to be uniform throughout the mass. Only one ore occurrence similar to the Boss has been known, but the total value and tonnage was insignificant. This was at Broken Hill, Australia, and was described by James F. Kemp, U. S. G. S. Bulletin 193, pages 84 to 86.

Authorities differ as to the origin of platinum ores, but the general opinion prevails that the known deposits originated from thermal springs. This theory does not seem applicable to the Boss, and it is quite certain that the platinum was once disseminated with copper throughout the mineralized zone, and that subsequent leaching and re-precipitation is responsible for the exceptional segregation of platinum metals, as found at this mine.

Manganese Mining in Brazil

*Imports of manganese ore into the United States have been irregular during recent years, the quantity in 1914 being 283,294 long tons. Of this, 113,924 tons came from Brazil. During 1915 Brazilian imports were of considerable importance, but were checked by shortage of ships, yet they contributed 90% of the imports to this country. Production of Brazil has increased to meet the large demand, the output in 1915 being 350,000 tons, an increase of 80,000 tons over 1914, and 170,000 tons over 1913, according to Joseph T. Singewald, Jr., and Benjamin Miller.

Except a small quantity of manganese from the State of Bahia, the output comes from Minas Geraes. The two productive districts are Miguel-Burnier and Lafayette a Queluz, 20 miles apart. The former is at the southern edge of the iron-ore region of Minas, and the latter a short distance south of it. Save the Rodeio, all operations in the Miguel-Burnier area are controlled by Carlos Wigg. The Rodeio has a monthly output of 1000 to 1200 tons; the other property produces 100 tons per day.

The Burnier manganese ore occurs in the Itabira iron formation, which is a sedimentary series of Algonkian age. It is the same formation that includes the great iron-ore deposits of this part of Brazil. Near the manganese mines it shows a rapid succession of itabirite, schist, calcareous schist, and limestone, mostly the first named.

At the Section 9 mine the manganese bed is from 33 to 50 in. wide, and 2000 ft. long. The mines are usually started as open-cuts, but as the orebodies are so narrow, underground work soon takes their place. The walls are soft, and considerable timbering is required. The ore is mostly of finely crystalline compact manganese oxides, with many lumps like those found in the brown iron ores. The ore contains 50% manganese, 1% silica, and 0.03 to 0.05% phosphorus.

The Queluz district is now the most important area. The principal mine is the Morro de Mina, producing 700 tons daily, owned by the Campañhia Morro de Mina, a Brazilian concern. The Mineraçâo de Agua Preta, a German corporation, produces 2000 tons per month of rubble ore from the east end of the Morro de Mina. A Belgian company, Société Anonyme de Manganese de Ouro Preto, mines 3000 tons monthly from its property south of Lafayette. A number of other mines are idle in this district.

Geologically the Queluz deposits are quite different from those at Miguel-Burnier. They occur in supposed Archean rocks consisting of granite, gneiss, and schist. The ore occurs as elongated masses of more or less lenticular shape within these rocks. The immediate wall-rock is thoroughly decomposed. Horses of similar material occur in the orebodies. The ore is similar in appearance to that of the Burnier district. The manganese content is from 48 to 52%, silica 2%, and 0.07 to 0.09% phosphorus.

The Morro de Mina is the largest manganese deposit in Brazil. In 1915 it yielded 200,000 tons, and 1,000,000 tons to date. Reserves are 10,000,000 tons, the largest in the world, according to the manager, J. de A. Lustosa. In the ore-bearing area of 300 by 800 metres are four important lenses. Mining is mostly by open-cut and by hand. Costs in 1914 were 60c. per ton. Freight to Rio de Janiero is $1.50 per ton and from there to the United States, $5 per ton. About 500 men are employed, who are well treated by the company. All ore is passed over a 2 cm. screen, the oversize being shipped. The undersize, about 15% of the total, containing 35% manganese, is stored for future washing or other treatment.

*Abstract from *The Iron Age*.

Ontario had 17 productive gold mines in 1915; of these 12 were at Porcupine. The Hollinger produced $3,000,000 from ore averaging $9.67 per ton; the Dome $1,325,000 from ore averaging $4.79; the Acme $900,000 from ore averaging $9.69; the McIntyre $747,000 from ore averaging $7.31; the Porcupine Crown $600,000 from $12.92 ore. The Tough-Oakes mine, at Kirkland Lake, produced $551,000 from $21.04 ore, or practically an ounce per ton. The mines of the Porcupine district have paid about $5,000,000 in dividends from 1910 to date. The 1915 gold production of Ontario was $8,386,956 or 44% of the total for Canada.

Mizpah trachyte, in which the principal large and rich silver veins at Tonopah are found, consists of 65.5 to 76.25% silica, 12.84 to 18.5% alumina, 0.1 to 3.86% ferric oxide, 0.16 to 1.8% iron oxide, 0.09 to 1.7% lime, 0.16 to 1.5% magnesia, none to 2.99% sodium oxide, and 3.2 to 6.31% potassium oxide.

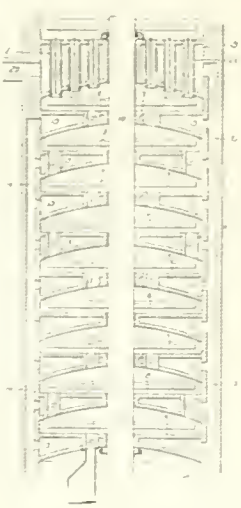
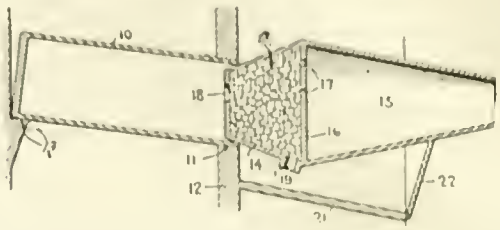
1. A concentrating table having a lateral reciprocatory motion and a series of settling areas, lateral ridges defining said areas and terminating at the concentrates discharge side of the table, said ridges being oblique to the direction of motion of the table and having oppositely sloping sides, riffles on the apices of the ridges and terminating short of the concentrates side of the table, means for discharging wash water on the ridges adjacent to the aforesaid side of the table beyond the riffles, and riffles in the settling areas parallel to and co-extensive with the first-mentioned riffles.

1,169,444.—Treating Metallic Sulfids, &c. Utley Wedge, Ardmore, Pa. Filed June 5, 1913.



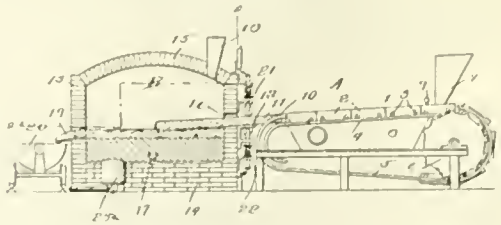
1. The within described continuous process of producing metal from sulfur compounds containing the same, said process consisting in first subjecting the compound, at a temperature sufficient to vaporize the sulfur, to an atmosphere containing a reagent which will oxidize the metal without promoting the oxidation of the sulfur, and then continuing the subjection of the oxid thus formed to a reducing atmosphere at a temperature sufficient to convert the oxid to metallic form.

1,167,925.—Apparatus for the Extraction of Zinc. Martin M. Pearlman, Clarksburg, W. Va. Filed Mar. 9, 1915.



1. The combination with means for the extraction of zinc including a retort having an open outer end, of a combined filter and condenser consisting of a hollow casing provided intermediate its ends with a transverse partition dividing the casing into an inner filtering chamber and an outer condensing chamber, the inner end of the casing fitting within the open end of and engaging the walls of the retort to form a closure for the same.

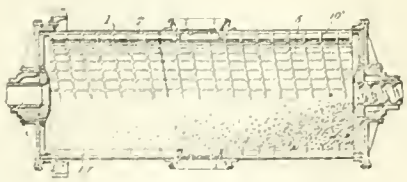
1,169,384.—Apparatus for Sintering and Smelting Ores. Arthur S. Dwight, New York, N. Y. Filed Mar. 31, 1910. Serial No. 552,579. Renewed June 12, 1915.



1. In an apparatus of the class described the combination of a moving platform adapted for the conveying of a continuous layer of ore, means for sintering the ore on the platform into a continuous cake, and means for passing an electric current through a portion of the cake adjacent its advance end, substantially as set forth.

2. In an apparatus of the class described, the combination of a means for forming and continually advancing a continuous layer of ore, means for sintering the advancing layer into a continuous cake, and means for passing an electric current through a portion of the cake adjacent its advance end, substantially as set forth.

1,169,276.—Construction of Tube-Mills and Linings Therefor. David Jack Nevill, Denver, Colo., assignor to The Stearns-Roger Manufacturing Company, Denver, Colo., a Corporation of Colorado. Filed Mar. 18, 1913.



1. In a grinding mill, a shell or casing, a lining therefor comprising a plurality of juxtapositioned sections, each section comprising a plurality of segments provided with longitudinal teeth and a transverse reinforcing rib, and means to expand said segments circumferentially in said shell or casing, said means comprising wedge shaped keys adapted to be inserted in positions laterally of the sections and having their outer faces substantially flush with the outer face of the lining sections.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

ELY, NEVADA

NOTES ON THE TUNGSTEN AREAS OF WHITE PINE COUNTY.

Mining of tungsten ore bids fair to be the largest industry in White Pine county, excluding operations of the Nevada Consolidated Copper Company.

It is reported that tungsten has been found in the Hamilton district, 45 miles west of Ely.

In Robinson canyon, 3 miles above Ely, just west of the old stage-station, Mr. Beech has found some hübnerite.

At Cherry creek, 50 miles north of Ely, west four miles through Cherry Creek canyon and two miles north on the west side of the range, the American Smelting & Refining Co. has taken over a large scheelite prospect. A Mr. Kimball of Salt Lake City optioned it to Nelson and others, for $30,000, making a 10% cash payment, then turning it over to the A. S. & R. Co. for $70,000. Recently the company has been moving freight from the railroad station to the mine, preparatory to active operations. Kimball retained a part of the ground, organized a company, sold some shares at 5c. each, and his development was so promising that he raised the price to 75c. Another company is being organized by Cherry Creek people for other claims nearby. Across Steptoe valley, from Cherry creek, on the east side of Shell Creek range, tungsten has been found.

Twenty-five miles south-east of this place, at Tungstonia (the Sims-Olsen property) for several months A. R. Shephard has been developing a hübnerite prospect. In the past two months, he has had a mill at work, making shipments of over 60% product. This is the largest producer known in this area, and probably in the United States. The main vein is 12 to 20 in. wide, traceable on the surface for 3000 ft. There are several other veins from 2 to 5 ft. wide.

Some 40 miles south of Tungstonia, at Sacramento pass, the Doyle Mining Co., organized and controlled by a San Francisco firm, has been operating a scheelite property several months. A small mill is operated.——South of Sacramento pass, 20 miles, on the west side of Snake range, and under Mt. Wheeler, the U. S. Tungsten Co. has been working a mill for many months with satisfactory results. The daily yield is about 1000 lb. of over 60% concentrate. Recently the company commenced some placer work (ground sluicing) and is finding a good deal of tungsten, including some large nuggets, without having reached bedrock. Both north and south from the U. S. T. Co.'s property, for some 8 or 10 miles in each direction, many prospects have been found and located.

In the neighborhood of Scheelite, a new camp on Willard creek, north from the U. S. T. mine, some Salt Lake City people have been developing all winter, under the management of A. D. Meyers. They have ordered a mill, which they intend to erect as soon as the condition of the roads permits its transportation.——There is considerable work being done on many prospects in this vicinity. South of the U. S. T. mine, some 20 odd miles, in the old Minerva district, 30 years ago work was done on several low-grade silver veins, which were abandoned. This was located late last fall by rancher Hudson as a silver property. Millick brothers and Jappy Fox found scheelite in the dumps, and a 5 to 6 ft. vein was opened in several places, containing 1% scheelite, with bunches of high-grade ore. They jumped Hudson's location, claiming that it was not properly staked, later agreeing to pay him $10,000 when sold. W. Stewart recently sold the property to Salt Lake City and Boston people. A payment of $3000 cash was made (which is 1% of the total price) over a period of 5 years, with a 20% royalty applying to the purchase price. These people say that they will install a mill in the near future. In four days two of the Millick brothers recently panned 265 lb. of concentrate from old dumps that assay 60%, worth about $600.

Over the range from the Minerva district, on the east side, and 8 miles west of Garrison, is the Bonita scheelite property of J. D. Tilford. About 8 or 10 months ago, he bonded and leased it to a San Francisco firm, who erected a small mill, and worked it until the water for steam and milling operations froze. Last month they gave up their bond and lease, owing to disagreements and the meddling of the owner.

South of the Bonita, at the head of Big wash, under Mt. Washington, at an elevation of 9500 ft., W. L. Chapman and A. D. Taylor late last fall discovered the best and highest grade scheelite prospect in the county. The deep snow in January drove them out, after having made several shipments of better than 70% crude ore. This week they are digging out the snow for an active campaign. About 40 miles south-west of the U. S. T. mine on Mt. Patterson, just across the line in Lincoln county, several veins of hübnerite were found late last fall. Many prospectors are going into the hills, though a little early, as only about one-third of the ground south-east exposures are now free of snow. It is probable that many of these large gaps will be filled in with new discoveries, making one of the largest tungsten areas in the United States.

On March 24 the Consolidated Tungsten Mines Co. was organized at Ely, with a capital of 500,000 $1 shares, to develop 30 claims on Williams creek, 45 miles south-east of Ely. J. D. Murphy is manager. A number of hübnerite veins have been opened, containing 1.4 to 13.39% tungsten. Mining is done by adits. Nevada Consolidated people are largely interested.

DEADWOOD, SOUTH DAKOTA

CUSTOM-MILL INVESTIGATION.—FREE ASSAYS FOR PROSPECTORS.—LITIGATION CLOSES MINE.—NORTH HOMESTAKE.—WOLFRAMITE FROM THE HOMESTAKE.

At the regular monthly meeting of the Deadwood Business Club it was proposed that investigation be made of the possibilities of erecting and operating a custom-mill at Deadwood. Considerable discussion ensued, and the matter was finally turned over to the mining committee, with a request that it look into possible ore-supply, cost of plant, and other matters. Preliminaries are well in hand, and as soon as the snow disappears from the mountains, the committee will get in the field and examine various properties which might be tributary to the mill. At a recent meeting of the committee there were present a number of mine-owners including Charles A. Chase general manager, and E. R. Graham, superintendent, of the Mogul Mining Co. The latter stated that at the Mogul they were prepared to receive, and were at present treating custom-ores; were willing to give financial assistance to lessees to enable them to secure machinery, tools and equipment; and to find lessees who would take over and operate properties that contained ore. It was also announced at the meeting that the Golden Reward and New Reliance mills treated custom-ores. Ore transport to the railroads received some consideration at this meeting, and Mr. Graham suggested that the com-

mittee examine into the feasibility of securing a motor truck which might be used in hauling ores at various near-by points. He thought that a 5-ton truck could be used to advantage, and would be of great benefit to mines that were from 2 to 5 miles distant from the railroads, such haulage, he thought, could be done at ½ to ⅓ the cost of haulage by horses. Altogether it appears that the discussion started will be of value to the mining industry. It will at least give some advertisement to the properties that the Club's committee will examine, even though the mill should not be built.

At a recent meeting of a joint committee from the Deadwood Business Club and the Lead Commercial Club with State Regent Albert Anderson and Dean O'Hara, of the State School of Mines, details of a plan were practically completed by which the institution will make assays of gold and silver for 25c., and qualitative determinations for tungsten free of cost. The samples must be sent to the School by the secretary or some other officer of one of the Black Hills commercial clubs, it being the intention of the School to extend this service to worthy prospectors. It will thus devolve upon the clubs to see that the School is not imposed upon. Further, it is the intention of the clubs to pay the fees to the School, so that the prospector will not be under any expense. This is the result of an effort made by the clubs to secure a free assaying service for the gold and tungsten seekers. The School is doing the work under authority given in a law passed by the State legislature in 1903, which established a State mining experiment station at the School, but for which no appropriation has ever been made. At the legislative session next winter a concerted effort will be made to secure funds to carry on the work, in which case assays might be free of cost and other assistance rendered the mining industry.

Mining and milling has been suspended at the Rattlesnake Jack property as the result of litigation between the owners, W. Sansom, of New York, and C. B. Harris, of Galena, S. Dak. Mr. Sansom is understood to have offered to buy or sell, and it is hoped that the affair will be settled out of court, for since Mr. Harris has established a home at Los Angeles, he has spent but little time at the property and desires to leave the country. The mine is a valuable one; it has been a producer for years and last summer a 10-stamp mill was completed and started. This plant is equipped for concentration and cyanidation, and of late has been making a recovery of about 93% on a $20 mill-feed.

Since development was resumed at the North Homestake last summer a drift has been run south from the 600-ft. station, a distance of 600 ft.; from its end cross-cuts have been advanced both east and west over 100 ft. each way. Practically all of this work has been done with the aid of a jackhamer mounted on a column. Quartz has been cut in the cross-cuts.

From the first two cars of wolframite which the Homestake shipped from the Golden Summit claim, more than sufficient was realized to reimburse the company for the purchase of the Hidden Fortune group, of which the Golden Summit claim is a part. The claims were purchased from the now defunct Hidden Fortune Mining Co. some two years ago. The Homestake now has the third car-load nearly ready for market.

TORONTO, ONTARIO

PORCUPINE, KIRKLAND LAKE, AND BOSTON CREEK DISTRICTS.—FLOTATION OF COBALT ORES.—NICKEL ONCE MORE.

Porcupine news is as follows:

At the Hollinger, recent developments on the 1275-ft. level are of a decidedly encouraging character. In sinking to this depth the winze passed through a quartz-porphyry formation, the gold-content of which was considerably lower than in the upper levels. The vein is now in the basalt, where the value is above the Hollinger average. The head-frame at the new shaft is nearly complete. The annual report of the company will be considerably delayed this year, as the staff has been weakened by enlistments in the army, and the final decision of the Government as to the war-tax on mining companies is being awaited.——The Dome Lake mill has been closed down for two weeks during the installation of the new cyanide plant, which is expected to be ready for operation about the end of March. Underground work is in progress as usual.——The new vein on the 100-ft. level of the Vipond has been opened for 165 ft., averaging $13 per ton. The ore is heavily mineralized and contains much free gold. Some ore has been found on the 500-ft. level, but nothing of consequence.——Sinking will shortly be resumed on the North Thompson. The shaft, now at 300 ft., will be deepened to 500 ft. Plans for a new mill are being considered.——The starting of the 150-ton addition to the McIntyre mill has been delayed by an accident in No. 5 shaft. It is proposed to haul the ore from the McIntyre Extension and Jupiter mines for treatment at the mill by motor-trucks, pending the installation of a carrier system.——At the Porcupine Crown the new steam hoist is in operation, and much development is being done at 700 ft. Low-grade ores are being developed on the upper levels. The mill is treating an average of 125 tons daily.——The Standard, south of the Dome Lake, is being developed by the Premier Gold Mining Co., controlled in Boston.

The Tough-Oakes at Kirkland Lake is treating about 120 tons of ore per day. The output in February is estimated at about $45,000.——The Beaver Consolidated of Cobalt is developing the McCane property in the Kirkland Lake area, on which it has an option for one year. The shaft is down 200 ft., where a station will be cut.——The Wright-Hargraves, east of the Tough-Oakes, which has a rich vein on the surface, is being opened.

There is a good deal of activity in the Boston Creek district.——The R. A. P. Syndicate has done about 180 ft. of driving on the 100-ft. level, where the vein is opening well with a good deal of free gold.——The Miller Independence has installed a boiler and compressor, and is erecting a small stamp-mill. A shaft has been started.——The Crown Reserve, which has under option the four McCrea-O'Neill claims, has cut a vein at a depth of 10 ft., 10 in. wide and rich in free gold.

Much interest has resulted at Cobalt by flotation tests conducted at the Buffalo. It is stated that flotation is suitable for Cobalt ores. The Buffalo has consequently decided to install a 600-ton plant for the treatment of tailings.——The McKinley-Darragh is installing a 150-ton flotation plant, which is guaranteed to save 500 oz. per day by higher extraction. Ore reserves at the end of 1915 were 1,875,000 oz., with an average of 15 oz. per ton, or only 257,820 oz. less than at the end of 1914.——At the Gifford-Cobalt the main shaft has been dewatered and machinery installed. Diamond-drilling will be done on the 200-ft. level to determine the extent of the ore-body, which is thought to be an extension of the Beaver vein system.

The nickel question is assuming a more acute phase, and appears likely to become a leading political issue. The feeling in favor of having all nickel ore refined in Canada is developing unexpected strength. A noteworthy sign is the stand taken by the Liberal press, which was until lately indifferent or opposed to any interference with existing arrangements. The conditions arising out of the War however, have brought about a complete change in public sentiment, and the agitation, which was formerly confined to extreme Protectionists and scaremongers, now receives the support of a large and influential element, on the ground that Imperial interests demand that the disposal of the product of Canadian nickel mines should be under strict Government control. In the present temper of the public the hand of the Government is likely to be forced, more especially as the Liberals evidently mean to take advantage of the movement as furnishing a good political cry. Before the War nickel was sold to the British government for 34.8c. per pound; the price is now 37.2c. The solicitor-general, Hon. Arthur Meigben, favors an export duty on nickel matte to encourage refining in the Dominion.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

The report of the territorial mine inspector, William Maloney, covers 1915. The estimated mineral production is $31,826,940, an increase of over $12,000,000. Copper contributed $14,633,950 and gold $16,752,000. There were inspected 168 placer mines, 31 quartz mines, and 30 dredges, employing 3000 men. There were 23 fatal, 92 serious, and 387 slight accidents. There was an ample supply of labor everywhere. Brief notes are given on all the mining districts. The names of dredging, lode mining, and placer companies are included.

Ketchikan

(Special Correspondence.)—Some increase in mining activity is noticeable in this district.

The Mt. Andrew mine has resumed operations after a brief shut-down during the winter. Small shipments are being made to the Tacoma smelter, and preparations are being made to increase the output.

The Goodroe mine will continue to ship ore to the Granby smelter at Anyox, B. C. This mine is unique, as bornite is the predominating ore-mineral, and it is the only locality in south-eastern Alaska where bornite has been found in quantity. Platinum is also present in the ore, and should receive payment owing to the present scarcity of the metal.

C. Lancaster has succeeded in interesting capital with a view to re-opening the old Sea Level properties.

At the Rush and Brown mine a large amount of ore has been broken in the stopes, and shipments will probably be increased to double the usual amount. Ore is being developed in the lower levels with good results in both grade and extent of orebodies. The magnetite ore is said to give better results in both copper and gold in the deeper workings than nearer the surface.

Ketchikan, March 7.

The Sea Level Development Co. has been organized at Seattle to re-open the old Sea Level gold mine in the Ketchikan district. The mine is near tidewater, where is a 30-stamp mill. Pumps are being installed, a hoist and compressor have been purchased.

ARIZONA

The State Bureau of Mines contemplates publishing a directory of the operating mines in Arizona, but is finding it somewhat difficult to keep up with the progress, as so many new mines are being started each day.

Gila County

(Special Correspondence.)—Considerable activity is evidenced in the mining districts around Payson this spring, owing partly to the visits of mining engineers to the region last fall. J. Parke Channing spent two days here and looked at a few of the prospects; other mining men have been here recently. Some shook their heads and murmured: "Too far from a railroad." It's awful to contemplate, but it's true. Yes, it is too far for timid spirits. Mr. Channing cheered us somewhat on that score when the fact of the great distance from the railroad was mentioned; he said: "One good producing mine will bring in a railroad soon enough." The high price of copper has stimulated the dormant interest in many prospects around Payson. Is it not like the trials of Tantalus to have such quantities of shipping ore? Assuming we were 25 miles to a railroad; add 80 miles to this and you have the distance by wagon-road to Globe or Miami; $60 ore does not pay; at least $75 ore must be extracted to make profits. Still we are shipping in small lots by parcel-post.

Boardman, McFarlane, and Pratt have made a number of shipments from the West Star, which assays 15% copper, $8 gold, and $4 silver. Others have shipped ore from the Silver Glance group, yielding $120 in gold, silver, and copper. Considerable development is planned for the coming season at the West Star. An adit of over 200 ft. will be driven to cut a 2-ft. vein at about 135 ft. depth.

On the Bailee group, A. J. McDonald has just completed an adit over 200 ft., for the purpose of cutting a high-grade gold vein at 140 ft. Assays returning $40 have been received, and a small mill will be erected. The George Washington gold prospect on the outskirts of Payson, owned by Mr. McDonald will also come in for a share of development this season.

Edward Oliver is now enlisting New York capital for the exploitation of gold claims situated about 4 miles west of Payson. Recently he opened high-grade ore on the Western Excursion, a west extension of the famous Excursion (patented). Four feet of low-grade ore just fills one end of a 50-ft. shaft in the Western. Mr. Oliver evidently hesitated in accepting the view commonly held that low-grade ore constituted the entire deposit, and on thorough investigation, about 14 in. of $20 ore was discovered outside the shaft in an open-cut. It was a red hematite ore on the hanging wall, the balance of ore being white, worth $6 per ton.

The Pittsburg Tonto Copper Co., formerly the Schell property, will resume operations this spring under the management of D. T. Clinton of Belle View, Pennsylvania. Shipments of 25% copper have been made from this property in the past. The vein is over 40 ft. wide, and contains 2% copper and $2.50 gold. An 18-in. high-grade streak of chalcopyrite, running with the dike from which the above-mentioned shipments were made, together with the prevailing high price of copper, seemed attractive to the newly-formed company which recently took over the 32 claims in the group. Not the least of the assets consists of the water-power of the Tonto river, 1500 miner's inches being available. The claims are on both sides of the river in the foot-hills of the Sierre Anches. The present owners propose to sink a shaft at least 200 ft. and will install a gasoline hoist and two drill-compressors immediately. Although 80 miles from Globe, the nearest railroad point, this handicap evidently does not deter venturesome spirits; in fact, greater obstacles have been overcome in the history of mining. More power to them.

Payson, March 12.

The 100,000 tons of copper ore in the Joe Bush dump of the Inspiration company is being removed before under-cutting and caving starts underground. The dumps at the Colorado shaft will soon be cleared away. Several parts of the ground surface show signs of caving operations.

On March 22 the International smelter at Miami dispatched East 40 and the Old Dominion 9 cars of copper, totaling 4,464,800 lb., a record shipment, from Arizona. It was valued at $1,195,000.

Mohave County

Californians, including A. C. Parsons, C. H. Gilman, H. H. Moore, and L. Tevis, have financed the Oatman North Star Mines Co. to exploit 250 acres in the centre of the Oatman dis-

trict. A shaft is down 80 ft. in the lode, but the main shoot is expected at 100 feet.

The Gold Road mill is treating ore from the Gold Ore company's mine, where rich ore has been opened to 530 ft. About 1000 tons will be treated.

At 515 ft. in the Nevada-Arizona, the Lucknow vein is 12 ft. wide, of good value. At 500 ft. is 9 ft. of $70 ore. The mill is to resume since a supply of water has been secured.

The Comanche and Pinkham claims at Chloride have been acquired by the Needles Mining & Smelting Co., which operates the Tennessee mine at Chloride and a reduction-plant at Needles, and is a subsidiary of the U. S. S. R. & M. Company.

Pinal County

Drilling at the Ray Hercules has found ore beyond the fault. Plans for the mill are being prepared by George Bradley. J. M. Callow will design the flotation plant.

Yavapai County

The Henrietta gold-copper mine has been exploited by the Big Ledge Development Co. since last October. The lower adit is in 1161 ft., with 450 ft. to go to be vertically under the main shaft. Three shifts are driving over 50 ft. per week with machines. Thirty men are employed. There is an equal number at the Butternut, two miles south of the Henrietta, owned by the same company. This is a copper-gold mine. In charge of the mines are L. E. Le Due and J. P. Trebilcock.

Backed by Chicago capital, in which F. A. Wheeler is the head, a 12,000-ft. adit is to be driven into the Bradshaw mountains to explore at a depth of 1800 ft. The portal will be a mile from the Crown King mine. The Fairview, Gladiator, Lincoln, Nelson, Spring Green, and War Eagle gold-silver mines will benefit by this drainage, development, and transport adit.

Ore crushing has been started at the old Yuma mine, 11½ miles from Tucson. A large sum has been spent on equipment and development. The mine was formerly a gold producer, but is now yielding tungsten and molybdenum, and $3 per ton in gold.

CALIFORNIA

Amador County

A club-house is being erected by the Plymouth Consolidated for its employees, a new departure on the Mother Lode.

Foundations are being laid for the new mill at the Treasure, near the Fremont at Amador City. The Fremont shaft is being sunk from 2350 ft. to 2750 feet.

The Old Eureka Mining Co. has been incorporated in Delaware with $3,000,000 capital for the purpose of pumping out and exploring the old Eureka mine, which was purchased in February from Mrs. Hetty Green by a syndicate headed by William B. Thornton. William B. Dickinson, Charles D. Frazier, Franklin E. Searle, Charles Briggs, Chester A. Congdon, and George E. Kenner. Only 100,000 shares, par value $10, will be issued now. The mine has not been operated since 1886.

Butte County

According to Richard Phillips, manager and controller of the South Banner mine, four miles north-east of Oroville, on the Feather river, a four-mile transmission line is being connected with the Oro company's mains to supply current for a central compressor-plant, which will give air for hoisting and other purposes. At present steam hoists are used at the South Banner and Amosky shafts, which are down 400 and 600 ft. deep respectively in good ore. The former is to be deepened 100 ft. Two 1000-lb. stamps are used for testing the ore.

Calaveras County

(Special Correspondence.)—The gravel mine owned by W. A. Swank has been incorporated under the name of the Gold Bar Mining Co. There is about 1½ miles of channel. It is expected that the mine will be in full operation within the next 60 days. J. J. McIntire is president and general manager.

The McCann gravel mine, in the Chili Gulch district, has been bonded and work has commenced. The adit is in 900 ft., and is opening the channel known as the Blue Lead. This was worked in the early days and yielded well.

The Bachman and the Big Four mines have been bonded by G. Allgewahr, of Fourth Crossing. They are near the Thorpe mine, which is in the hands of Eastern capitalists, and under the management of Mr. Allgewahr. Work on the Bachman and Big Four will be started as soon as possible.

San Andreas, March 18.

The new mill of the Calaveras Copper Co. is treating 200 tons of ore daily, yielding 16 to 19% copper concentrate. This quantity is to be increased by 50%. A new coarse-crushing plant is to be erected at a cost of $15,000. Mine development continues satisfactory.

Napa County

A number of old quicksilver mines near Calistoga are being re-worked. At the Oat Hill 40 men are employed.

San Bernardino County

Optimistic news comes from Atolia, which now has a weekly called the *Tungsten Review*. New discoveries are reported and claims change hands. Placer scheelite continues to be found in fair quantity. Good progress is being made with the Atolia company's new mill, which will be larger than the one burned. The ore is broken in a 10 by 18-in. Joshua Hendy crusher, and further reduced by rolls. Half of the product is fed to two 5-ft. Huntington mills. The discharge passes over two Deister roughing-tables, where the richest material is extracted. From the tables it passes to vanners. The other half of the material goes to an 8-ft. Marcy ball-mill, the capacity of which is from 30 to 40 tons per 24 hours. The crushed ore is discharged through a 30-mesh screen onto a Deister roughing-table. From there it goes to a Dorr classifier. The slime from both units is thickened for concentration by three 8-ft. Callow cones, and then passes over three double-deck Deister tables. Tailing is stored for future use. The tailing runs from 1 to 3% calcium tungstate. A conservative estimate places the amount available for treatment at 200,000 tons.

Each separate piece of machinery has its individual motor, there being more than 25 motors required. The mill will use 30,000 gal. of water each day when at full capacity, and it will produce from 5 to 7 tons of concentrate per day. This, together with the output of the jigs, will make the average daily production of tungsten concentrates about 7 tons. The No. 1 mine will soon be lighted by electricity. An electric hoist is to be installed at 900 ft. to serve the prospecting winze below that depth.

The Pagh placer, in the Stringer district, has changed hands for $5000.

Shasta County

At Kennett the Mammoth company has three copper furnaces in blast treating its own and Balaklala ore. Good progress is reported from the long adit being driven. The Greenhorn copper mine, near Tower House, has resumed shipments to Kennett.

The Afterthought copper mine at Ingot is under option for sale. Zinc was a nuisance in treatment several years ago.

Siskiyou County

On the Grenada section, about 6 miles from Montague, near the Southern Pacific line, the Shasta Development Co. is to drill for oil. Two 13-in. holes will be put down. Oil may be struck at 2700 feet.

Tuolumne County

(Special Correspondence.)—The Atlas mine near Tuttletown has a new body of ore, and the future of the property looks promising. J. Whitney is superintendent.

The Saratoga gravel mine, adjoining the Springfield Tunnel

property, is being worked under new management, and gravel will be mined in the near future.

The Street mine in the Tuttletown district has been unwatered by San Francisco people. It is equipped with a five-stamp mill.

The old Patterson, with a past production of $1,500,000, is to be unwatered shortly.

Tuttletown, March 18.

Yuba County

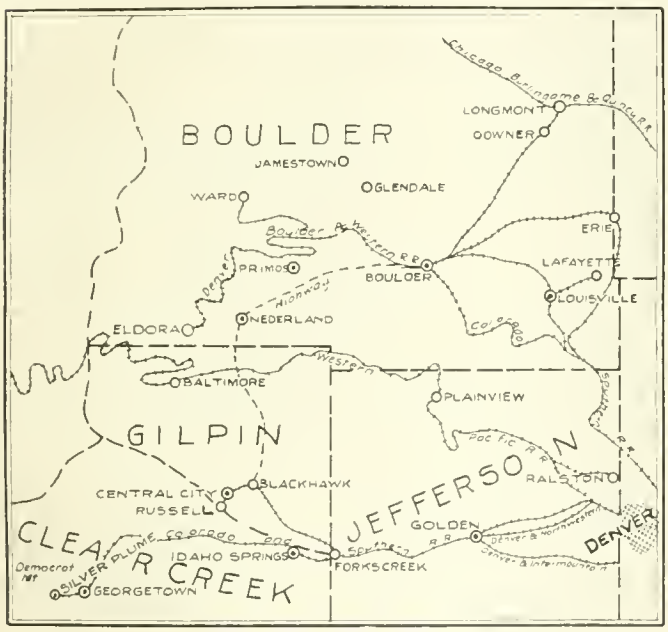
On March 26 No. 15 dredge of the Yuba Consolidated company was launched at Hammonton, the ceremony witnessed by 2000 people. The buckets are of 17 cu. ft. capacity and will dig to a depth of 82 ft. Work is to be started on No. 16. The Yuba Construction Co. builds these boats.

COLORADO

Boulder County

According to A. P. Ardourel of Boulder, he has sold one of the largest tungsten properties in the Nederland district for $200,000 to New York people.

There is keen competition among tungsten-ore buyers, resulting in $90 per unit being paid by the Colorado Tungsten Mines Co., which is higher than that offered by the Boulder Tungsten Production Co. W. M. Long is in charge of the former company, which has a mill at South Boulder. The Boulder company is making large profits from its custom plant, over $1000 per day. The mine adit is in 500 ft., and yields 35 tons of 4% ore daily.



THE TUNGSTEN DISTRICTS OF BOULDER COUNTY, COLORADO.

The Mojaba Mining Co. of New York has bought the tungsten claims of Chris Bracken at Boulder Falls for $100,000. A mill will probably be erected.

Clear Creek County

(Special Correspondence.)—The Mosher lease at the Lake mine, situated on Pewabic mountain, was sold this week to E. D. Quigley of Denver, representing Oklahoma people, for $15,000 cash. The ground controlled is above the Big Five adit-level, and extends to the end-lines of the claim, a distance of 1200 ft. During the past 18 months Mosher & Co. have been credited with a production of $200,000.

E. Renner & Co., leasing at the Bellevue-Hudson mine, have opened a 10-in. streak of smelting ore for 20 ft. that assays as high as 1800 oz. silver per ton.

J. J. Hoban, manager of the Wyoming Valley company, states that as soon as the frost is out of the ground excavation will be started for a compressor-plant. The adit is in 600 ft., and within 800 ft. the French Flag-Silver Age properties will be completely drained.

The sum of $40,000 was deposited in the Bank of Georgetown this week to be used in equipping the Malm mill at Georgetown. Mrs. Alice H. Brownlee of Idaho Springs, who is financing the scheme, states that the plant will be completed and in operation within 90 days.

Idaho Springs, March 17.

The old Colorado Central mine has been acquired by oil people, who have re-opened it after many years' shut-down.

IDAHO

Blaine County

A good revival in mining is expected this season in the Wood River region of central Idaho, of which Hailey is the centre. In 1915 the output of the county was 1405 oz. gold, 120,000 oz. silver, 1,200,000 lb. lead, 1,110,000 lb. zinc, and 6000 lb. tungsten. A good lead-silver development was made in the Red Elephant company's adit. It is considered as important, and proves that failure of the old Bullion veins of the district was due more to faulting displacements than from exhaustion of the ore in depth. Zinc is also being mined in the district, the largest company being in granite. The Camas lode, 12 miles west of Hailey, occurs in granite, and is worth larger exploitation.

Idaho County

Around Elk City there are over 100 men employed. The Mineral Zone or Parr property produces 16 tons of gold ore daily. At the South Fork mine on the Clearwater river five stamps are dropping. A mill is to be erected at the Center Star. Good developments are reported from the Grangeville, Black Pine, Hercules, and Cumberland. The Buffalo Hill placers are to be re-worked. A dredge to replace the one constructed six years ago is to be built by the Elk City Dredging Co. of Spokane. The ground was prospected last year by a Keystone drill, averaging 35c. per cubic yard.

The old Hogan mine near Orogrande, 50 miles from Grangeville, is to be re-opened. Debts have been paid, and sufficient capital secured for operation. Several lode and placer properties near Orogrande are promising.

Shoshone County (Coeur d'Alene)

During February the Interstate-Callahan produced 5810 tons of zinc and 455 tons of lead concentrates, yielding a profit of $278,287.

A first-aid contest was held at Kellogg on March 13, between 9 teams (54 men) from the Bunker Hill & Sullivan mine and mill. The K. T. Dump team won with 96%, Mill Carpenters' team second with 89.25%, and Mill team third with 89%. Good prizes were given. The manager, Stanly A. Easton, presided at a banquet following.

Rich tungsten ore continues to be produced by the Golden Chest and other mines near Murray.

A 150-ton mill is to be erected at the Constitution mine on Pine creek this summer. A saw-mill will cut lumber from the property.

On April 5 the Caledonia company will pay a dividend of 3c. per share, equal to $78,150.

MICHIGAN

The Copper Country

(Special Correspondence.)—Exploration on the lands of the Torch Lake company will probably commence early in the spring. This company owns two sections in what now seems to be promising mineral territory, which extends from the Kearsarge lode to the sandstone. Recent developments at the

New Arcadian have an important bearing. The surface has been occupied by farmers for many years, 20 or 30 years, in fact. Twelve years ago some diamond-drilling was done, but the results were not encouraging. In fact, only one core showed commercial value.

There is no producing mine in the Lake Superior district which seems to have as bright a future as the Allouez. People here do not fully appreciate the possibilities of this mine for the reason that the property has been, for a period of 10 years, a practical failure.

The Trimountain stamp-mill of the Copper Range Consolidated Co. will be rebuilt. This mill, at Beacon hill, about midway between the Champion and Baltic mills of the same corporation, had a number of advantages, particularly of site.

At the Quincy stamp-mill No. 2 head has a new foundation. All of the 24-in. low-pressure stamp-cylinders have been replaced with the old 20-in. cylinders for higher steam pressure. In No. 1 mill, 21 small type bull-jigs have been installed, and 12 in No. 2. Three more rollers have been put in No. 1, making roller equipment similar to that of No. 2 mill.

The average pay to miners working in the Calumet & Hecla mine for February was $4.35 per shift. Practically all of these miners work on contract, a system that has been in vogue in the C. & H. since the earliest days. This compensation compares favorably with the wages paid miners in any copper centre in the world, and these employees receive advantages in house-rentals and other ways that make for certain reduction in the cost of their living.

Notwithstanding the large amount of conversation that continues to find its way into print relative to the purchase of the Tamarack by the Calumet & Hecla, the general belief here is that no such deal ever will be consummated. The C. & H. interests are indifferent on the subject. They will buy no lawsuits, however. They do not wish to take over Tamarack unless they can take it over with absolute assurance that there are to be no recalcitrant stockholders to make trouble, and start suits about it. And they are willing to sell their interest in Tamarack for substantially less than it cost them or they will buy out others.

Houghton, March 20.

Exploration at the White Pine Extension has been so satisfactory that the company is to build a railway six or seven miles to the White Pine line.——Mineral (66% copper) is to hauled from the White Pine mill to the Hubbell smelter in small steel cars.

The Calumet & Hecla reports as follows for February:

Mine	Copper in pounds	Mine	Copper in pounds
Ahmeek	1,544,671	La Salle	84,993
Allouez	814,142	Osceola	1,803,838
Calumet & Hecla	6,011,570	Superior	253,098
Centennial	172,620	Tamarack	650,626
Isle Royale	854,435	White Pine	313,573

MISSOURI

Jasper County

With a mine in sheet-ground and a 350-ton mill, the Milan company at Prosperity sold its property last week to W. Kenefick and others for $125,000.

The better spelter market reflected on the ore market last week, the range being from $90 to $115 per ton. The output of the Missouri-Kansas-Oklahoma region was 3997 tons blende, 508 tons calamine, and 1136 tons lead, averaging $98, $68, and $94 per ton, respectively. The total value was $536,484.

MONTANA

According to C. S. Warren, of Butte, recently at Spokane, more prospectors than ever will commence in Montana when the snow clears away. The country will be finely combed, as it were.

Lewis and Clark County

In the Grass Valley district, four miles west of Helena, there is increased activity. Favorable reports come from the Rock Rose and Carbon Hill mines, the latter a silver-lead property.

Developments are encouraging in the Eastern Belle, Madden, and Allen, in the Scratch Gravel district, which was recently visited by Helena businessmen.

The Helena Mining Bureau is busy in the old Park gold district, six miles south of Helena.

Silverbow County

The North Butte company's Granite Mountain shaft is 3165 ft. deep, on its way to 3600 ft. A station will be cut at 3200 ft. A wide lode has been cut at 700 ft. The monthly output is 2,250,000 lb. copper.

The Butte & Great Falls company has purchased the Dewey and four other claims adjoining the company's property, for $50,000 cash and 25,000 shares. H. H. Hanson owned the Dewey. The Butte & Great Falls is well financed for extensive exploration.

NEVADA

Esmeralda County

A Davis-Calyx drill is being installed at 700 ft. in the Silver Pick Consolidated. Good ore is being opened at 500 and 600 ft., according to G. F. Dyer, the manager.

Surface prospecting by the Reorganized Cracker Jack company has given fine results, three well-defined veins, yielding gold by panning, having been stripped for a considerable distance. A hoist, compressor, machine-drills, etc., have been ordered.

During 1915 the Goldfield Consolidated Mines Co. produced 385,900 tons of $10.37, and 4154 tons of $23.53 ore. The profit was $1,558,308. Dividends absorbed $1,601,617. Development covered 34,603 ft. Total costs were $1.03 per ton lower.

The 50-ton flotation plant at the Goldfield Consolidated is giving 90% extraction on the gold-copper ores.

During February the Jumbo Extension produced 2595 tons of ore worth $79,000, of which $25,000 was profit.

Humboldt County

In reply to a correspondent who asks where antimony occurs in this county, we would say in the Antelope Springs, Bloody Canyon, Jackson Canyon, Juniper Mountain, Lovelock, Red Butte, Rosebud, Seven Troughs, Star Canyon, and Winnemucca districts.

Nye County

Additional water supply has been secured for the Round Mountain Mining Co. by purchasing the Round Mountain Power & Water Co.'s properties, including the water of Jefferson and Shoshone creeks. This will allow of more extensive sluicing at Round Mountain.

Ten mines at Tonopah last week produced a total of 8544 tons of ore worth $179,052.——The Belmont shipped 173,155 oz. bullion.——The Tonopah Mining Co. has declared its regular quarterly dividend of $150,000. At the mill an average of 53 (out of 100) stamps is crushing 1950 tons of $15 ore per week. ——The Rescue-Eula continues to produce 15 to 20 tons daily from the new shoot.——For the first two weeks of March the West End cleaned-up 55,619 oz. bullion, worth $42,000.—— During February the Extension treated 7085 tons for 177,618 oz. bullion, and $60,523 profit.

NEW MEXICO

The 'Advancement Number' of the *New Mexico State Herald* of Santa Fe consists of 64 pages devoted to all industries in the State, which produced $100,000,000 in 1915, mining contributing 20%. The State has an area of 122,503 square miles and a population of 360,000. Some good illustrations show the work of the Chino Copper and other companies.

WASHINGTON

STEVENS COUNTY

A carload of lead bullion is shipped daily from the Northport smelter to its refinery in Pennsylvania. This is from one furnace. The smelter yard has a good stock of concentrate awaiting reduction. Another furnace is soon to be blown-in.

WISCONSIN

IOWA COUNTY

(Special Correspondence.)—The New Jersey Zinc Co. at Highland has its new 8 by 18-ft. shaft in the clear in the largest deposit of blende and zinc carbonate ever opened in this district. The 'range' has been proved by drills to be nearly a mile long and over 150 ft. wide. Carbonate ore is selling at $60 per ton, basis of 40% zinc. This district is noted chiefly for extensive deposits of this class of zinc ore.

At Mineral Point the works of the New Jersey Zinc Co. is engaged in the manufacture of zinc oxide and sulphuric acid. At the former, 300 men are employed and the plant is always busy. The warehouses contain 40,000 bbl. of finished oxide, and large shipments are made daily. Four to seven 25-ton tank-cars of commercial sulphuric acid are shipped weekly; 80 men are given employment in the acid department. Two zinc ore refineries are kept going constantly, employing 100 men.

At Mifflin the two Coker mines, on a single deposit of zinc ore, and owned in fee by the New Jersey Zinc Co., are producing 1700 tons of mill ore daily. Shipments of concentrate average 350 tons per week, all sent to separating plants at Mineral Point. There are eight other active shippers in this district.

Mineral Point, March 16.

CANADA

BRITISH COLUMBIA

At the Granby Consolidated company's Hidden Creek mine daily shipments to the Anyox smelter are 2500 tons of 2 to 3% copper ore. About 400 miners and 600 smelter-men are employed; the former receive $3.50 per shift, with a bonus of 25 to 75c. per shift, according to the price of copper. At Phoenix the mines are sending 3000 tons per day to the Grand Forks smelter. Employees are 400 and 200, respectively. The Mamie mine at Hadley, Prince of Wales island, Alaska, sends 200 tons per day to Anyox. Other small mines contribute. During the second half of 1915 the Anyox and Grand Forks plants reduced 377,660 and 571,502 tons of ore, respectively, yielding a total of 19,894,527 lb. copper, 22,034 oz. gold, and 188,649 oz. silver. The profit was $1,513,181. Dividends absorbed $449,955.

Hydraulicking will be started toward the end of April at the Union mine on Siwash creek, near Vernon, according to the superintendent, J. S. House. One No. 5 giant, with a 5 to 7-in. nozzle, is used under a 110-ft. head. The gravel channel is 200 ft. wide, and a maximum bank of 90 feet.

Better zinc-silver ore has been opened on No. 7 and 12 levels of the Rambler-Cariboo than in the upper levels.

KOREA

During December the Oriental Consolidated company's output was $144,472 from 26,621 tons.

The three mills worked steadily during December, as there was plenty of water, and there were few stoppages of Okura's power supply. The extraction obtained in the Taracol cyanide plant was 89%, while that for the Maibong tube-mill was 106%, the latter due to a hang-over in the zinc-boxes, from the previous month, when the extraction was only 75.7%. It is hoped to be able to maintain a more even output from the Maibong tube-mill as soon as all details are arranged in routine order. The February output was $116,800, a reduction due to lower grade and short month.

PERSONAL

J. B. TYRRELL is in London.

HORACE V. WINCHELL was at Grass Valley this week.

H. G. WRIGHT is superintendent of construction at Anaconda.

W. G. PERKINS has transferred his offices from London to Petrograd.

J. A. AGNEW has returned to London from the United States and Mexico.

WALTER H. WEED was in San Francisco on his way to Mariposa county.

ARTHUR W. JENKS has been examining mines in Mariposa county, California.

H. E. COLLBRAN, treasurer of the Seoul Mining Co., was here this week from Denver.

HARRY L. ROSCOE is chemist for the Quincy Mining Co., succeeding ROBERT F. WOOD.

ROBESON T. WHITE sailed from New York on March 18, returning to the Caucasus.

F. J. BRULE is superintendent of construction at the Great Falls zinc plant, Montana.

W. J. KELLY is now in charge of the Douglass mine, in the Pine Creek district, Idaho.

M. R. HULL has left Anaconda to become chief engineer to the Arizona Copper Company.

WILLET G. MILLER is in London in connection with his work on the Ontario Nickel Commission.

EDMUND JUESSEN has resigned his position of consulting engineer to the Engels Copper Company.

GORDON R. CAMPBELL, of Calumet, Michigan, secretary of the Calumet & Arizona Mining Co., is in Arizona.

JAMES W. ABBOTT is lying seriously ill at St. Luke's hospital in this city. He is recovering, we are glad to add.

M. YAMASHITA, of the Ikuno mine, operated by Mitsubishi & Co., left on the *Tenyo Maru* for Japan on March 28.

CHARLES J. STAKEL, of the Cleveland-Cliffs Iron Co., is now superintendent of the Republic mine at Republic, Michigan.

EDWIN E. CHASE has taken his son, R. L. CHASE, into partnership, with new offices at 1028 First National Bank building, Denver.

BRENT N. RICKARD, assistant superintendent at the Monterey plant of the A. S. & R. Co., was married in San Francisco last week.

ASSOCIATES OF THE ROYAL SCHOOL OF MINES and other former students in that college of mining are requested to get in communication with E. B. LICHTENBERG, the secretary of the R. S. M. Association, which is an organization founded in 1914 to promote the best interests of the School and of its graduates.

Obituary

CARLOS E. HUSK, surgeon-general of the mining department in Mexico for the American Smelting & Refining Co. died on March 20 at Laredo, Texas, of typhus fever. Dr. Husk had conducted a party of physicians, consisting of Dr. Peter Olitsky and Dr. B. S. Denzer, of Mount Sinai hospital, to Matehuala, to combat typhus among the employees of the company, and a great deal of good had been accomplished. Both Dr. Husk and Dr. Olitsky were striken with the fever, and were taken to Laredo in the special train with the company employees who had been instructed to leave Mexico. Dr. Husk was very well and favorably known among the mining fraternity in Chihuahua and other parts of Mexico. He had resided in Santa Barbara, Chihuahua, for several years, having charge of the company hospital at that place. He was interested in several mining properties in the vicinity of Santa Barbara. Dr. Husk leaves a wife and a host of friends to mourn his loss.

THE METAL MARKET

METAL PRICES

San Francisco, March 28

Antimony, cents per pound	41
Electrolytic copper, cents per pound	29
Pig lead, cents per pound	$8.00 — $8.00
Platinum: soft metal, per ounce	$88
Platinum: hard metal, 10% iridium, per ounce	$92
Quicksilver, per flask of 75 lb	$200
Spelter, cents per pound	22
Tin, cents per pound	46
Zinc-dust, cents per pound	30

ORE PRICES

San Francisco, March 28

Antimony: 50% product, per unit, of 1%, or 20 lb	$2.25
Chrome: 40% and over, f.o.b. cars California, per ton	$8.00
Magnesite: crude, per ton, f.o.b.	$8.00
Magnesite: plastic, no iron and lime, calcined, ton	25.00—30.00
Magnesite: refractory, 1% iron, dead-burned, ton	35.00
Manganese: 50% metal, 8% silica, per ton	12.00
Tungsten: 60% WO_3 per unit of 20 lb	70.00—80.00

A recent settlement for 71.1% tungsten concentrate at Boulder, Colorado, was at the rate of $85 per unit. The Colorado Tungsten Mines Co. is paying $90 for 60% product. Later on last week a buyer at Boulder advanced the price to $105. Nineteen tons of mixed grades of wolframite from the Wasp No. 2, South Dakota, realized $83 per unit.

New York, March 22

Considerable business has been done in antimony ore, sellers making concessions in price. On March 21 the price was around $2.60 per unit.

Spot tungsten ore continues in demand, and $85 per unit has been paid and $90 reported.

EASTERN METAL MARKET

(By wire from New York.)

March 28.—Copper is fairly active and firm; lead is firm but quiet; spelter is steady but dull.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending	
Mch. 22	58.50	Feb. 16	56.62
" 23	59.37	" 23	56.86

On the basis of 80% metal, ore at Joplin is selling at $100 per ton.

The U. S. S. & R. Co. is said to have a large stock of lead which will be sold at high prices. In 1915 the company produced nearly 90,000,000 lb. of metal, and in 1916, 100,000,000 lb. is expected.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. Prices, in dollars per flask of 75 pounds:

Week ending

June	30.72	40.26	....	Dec.	33.60	38.71	....

Tin is firm at 49.50 cents.

Eastern Metal Market

New York, March 22.

The situation in lead continues to dominate interest of the market. The independent producers are getting 8c. and over, New York, while the A. S. & R. Co. here continues to quote 7c. Its quotation is nominal, however, as it will not sell at that price. It is offering April shipment on the basis of its own average price for the month, and not on the price it may quote from day to day. Its latest move is supposed to be in furtherance of its desire to check the runaway market. The domestic and foreign demand is heavy. Copper is firm, but quiet again, after a brief spurt of activity. New England consumers still find difficulty in getting the metal they have purchased, because of the freight embargoes. Zinc is also quiet after a few days of buying, during which prices rose again. The tin situation is much easier because of fairly large arrivals in the past few days. Antimony is scarce for immediate delivery, and the price is stronger. Aluminum is quiet and unchanged.

The great difficulty today is in finding metals which can be delivered promptly and this fact, together with the abnormally high prices, is imposing a strain on consumers, of which they are complaining. It will be realized that they would suffer a heavy loss should there be any substantial decline in the metals they use, especially if they have contracted far into the future. This does not matter so much with the War business, but industrial consumers feel that they are in danger and are worried.

COPPER

After a spurt of activity which lasted but two or three days, in which a moderate tonnage was taken, the market is dull again, but slightly firmer. Near-by metal is easier to obtain, but most of the interest continues to be in forward positions, consumers being well supplied so far as their immediate needs are concerned. June and July deliveries of electrolytic range from 26.50 to 27c., while prompt is quoted at about 28c. Some sellers are asking 27.50c., cash, 30 days, but this is because they have little to offer. Lake, for July and later delivery, is quoted at 27.12c. Activity in copper has been retarded by the freight situation in New England, some of the mills in the Naugatuck valley having shut-down for lack of materials, while others have curtailed operations. In one case, a carload of Lake copper was shipped from Buffalo, N. Y., to a point in New England by express at an extra cost to the consumer of several hundred dollars. The producers show firm faith in the future, and are holding to their quotations, paying little heed to concessions offered by second-hands. The London electrolytic market has stood at £136. European statistics received here on March 17 show decreases in the stocks of copper in the United Kingdom and in France. The figures show that on the 15th they totaled 7988 tons, against 9811 tons on February 29, and 8777 tons the 15th. Exports up to and including March 21 amounted to 12,567 tons.

ZINC

From March 14 to 21 quotations for zinc climbed upward under the stimulus of fairly good buying, especially for April, May, and June delivery. Spot, which is extremely scarce, sold at 18.25c., New York; March commanded 17.75c.; April, 17.25c.; May, 16.75c.; and June, 16.25c. The London market is stronger and has imparted some of its strength to the New York market. The spot quotation at London on the 21st was £92. As in the case of copper the market has been adversely affected by the railroad-freight conditions in New England, consumers not seeking to buy more metal when they cannot get what they already have bought. Viewed in its entirety, the week has not presented many features of interest, and to a large extent the market is a waiting one.

The quotation for sheet-zinc is unchanged at 25c., in carload lots, f.o.b. mill, 8% off for cash. Exports totaled 1295 tons.

LEAD

The situation in this metal is mixed and without precedent. Prices are hard to determine, when it is desired to give a definite figure. The A. S. & R. Co. is nominally quoting 7c., New York, but it is not selling for March delivery at that price. On April deliveries it does not quote, but will accept business on the basis that the price to be paid will be the average of its own quotations for that month. This lends uncertainty to what the buyers will be called on to pay, and perhaps explains why so many of them are paying the premium prices demanded by independent producers. The latter have been getting up to 8c., New York, and over. Up to the present time, and since the quotations of the outsiders exceeded those of the leading interest, it seemed fair to give as the market, the average of the A. S. & R. Co. quotations and those of the independents, but since the big producer is not selling, except under the arrangement referred to, it seems more fair to quote the prices of the independents, and in the future this will be done as long as they do business at prices over those of the A. S. & R. Co. So far as prompt business goes, the quotations of the big interest are pronounced as fictitious by the trade. It is following its course with a view of checking the upward tendency of the market, but so far it has failed. Russia and Japan have continued heavy buyers, the latter in particular being eager to get the metal. Sales have been made at 8 to 8.12c., delivered at Pacific ports. On March 16 sales were made at 8 to 8.25c. f.o.b., smelter, and on the following day there was business on the basis of 8c., New York. One inquiry which came out this week called for 1000 tons for export, and in this case one producer refused to quote on the ground that it was his duty to care first for domestic consumers. The demand has continued heavy, munitions' needs being behind most of it. At the present time the market is strong, and there is talk of 10c. lead. Exports of this month, up to and including the 21st, totaled 3473 tons. The London market is strong at £36. The high price now prevailing in New York has brought out some re-sale lead, a few consumers being among those willing to sell.

TIN

The strong market for spot tin has broken under the influence of larger arrivals, some of which were unexpected. Up to yesterday the month's imports totaled 2378 tons. The steamer *Suruga*, from Singapore, arrived on the 20th with 1135 tons, and this arrival alone was enough to ease the market. In addition, however, there were other arrivals of 100, 215, and 400 tons, as well as some smaller ones, and in the week spot tin dropped from 54 to 49.62c., the quotation of the 21st. The week has been a rather quiet one, although on the 20th between 300 and 400 tons was taken at 50.50c. The quantity now afloat is 5450 tons. In March, at least, there is now no danger of any shortage, and somewhat easier prices may be expected. The situation at London, in the matter of shipping licenses, continues uncertain.

ANTIMONY

Chinese and Japanese antimony is quoted at about 45c., duty paid. Spot metal is extremely scarce, and deliveries are uncertain because of the upset freight conditions. For instance, a buyer expected to get some antimony from the Far East by way of a Southern railroad, but it came by way of the Canadian Pacific, and when it reached the northern part of New York State, the New York Central Railroad refused to handle it. Japanese sellers are reported to have made some concessions in their prices. Forward shipments are quoted at 34c., in bond. Needle antimony is quoted at 23.50 to 24 cents.

BOOK REVIEWS

THE FLOTATION PROCESS. Compiled and edited by T. A. Rickard. P. 364. Ill., index. For sale by MINING AND SCIENTIFIC PRESS. Price, $2.

It is fairly safe to say that flotation is in course of producing a greater revolution in the world of metallurgical method than any other process that has been introduced since the cyanide process for the extraction of gold and silver. Not only is it exercising the minds of those interested in the recovery of copper, lead, and zinc, and other base metals, from their ores, but it is even encroaching on the territory of gold and silver, where the cyanide process has for many years been almost impregnably entrenched. The appearance therefore of this publication is particularly appropriate at this time. The book is a compilation by the Editor of the MINING AND SCIENTIFIC PRESS of all the articles that have appeared on the subject in that paper during the past eight or nine months.

The volume starts with a useful glossary of terms employed in the process, and the opening chapter consists of a paper by T. A. Rickard presented to the Canadian Mining Institute at the March 1916 meeting. This paper, though the latest of all in chronological order, is intended to act as a general introduction to the subject, and it answers this purpose admirably, discussing in turn the physics of the process, the various methods and devices for applying it, the history of its inception and development as illustrated by the various patents secured to protect it, and commenting on the psychological factors involved in its career. With the exception of this opening chapter all the articles follow one another in the order of their publication, an arrangement adopted to facilitate the linking together in the mind of the reader of the various ideas and arguments as they were consecutively developed from week to week by the different writers.

A large proportion of the articles consist of attempts to formulate a workable theory to account for the phenomena displayed, and though this aspect of the matter may seem to some readers of less practical importance than that of the commercial results of the process and the *modus operandi* of tests and working plants, yet those who are occupying themselves in the business of theoretical research are performing a very real and practical service for the industry, because up to the present experimental work in the application of the process has been almost entirely empirical or, in other words, has been conducted on the "hit or miss" method. It is obvious that if definite rules could be formulated that would determine beforehand, if only approximately, the methods and conditions necessary for any given class of ore, progress on the commercial side would be much more rapid.

In this effort to get at underlying principles it is inevitable that divergent views should be freely expressed, but when this leads to friendly criticism and discussion, as is the case in the present instance, a real advance in the knowledge of the subject is likely to result.

The two articles by T. A. Rickard entitled 'What is Flotation?' were designed to set forth in simple language for the benefit of the uninitiated the somewhat meagre information at that time available, and the fact that the author was himself *in statu pupilari* as regards flotation does not detract from the usefulness of the work. Even if some of his statements do not quite square with the theories of the experts, his fearless expression of them has succeeded in causing some, at least, of these experts to come forward and expound their views to the public, and has aroused an interest in the fundamentals of the process that is not likely to subside for some time to come.

The discussion thus started by the Editor of the MINING AND SCIENTIFIC PRESS has elicited a number of valuable contributions to the theory of the process, among which those of Messrs. Durell, Ralston, Norris, and Coghill seem especially suggestive. The first named propounds a theory that gas bubbles mechanically held in a pulp are powerless to float mineral particles, and that to be effective the gas must go into solution in the liquor under such conditions that it is liberated, or brought into being as a bubble, at the surface of the particle it is destined to float. This is a possible hypothesis, but the arguments he adduces seem hardly conclusive, and evidence to the contrary as cited from the case of Minerals Separation, Ltd. v. Miami Copper Co. in a communication by James A. Block. He is also committed to a theory that gases occluded in the mineral particles play a vital part in the physics of flotation, a view that is strongly contested by Mr. Ralston, who offers two alternative hypotheses, one based on the action of interfacial tensions, and the other on the electrical charges carried by suspended particles. This electrical theory of flotation is further advocated by Thomas M. Hains and discussed in more detail in a paper by F. A. Fahrenwald. The phenomena and laws of surface tension are set forth in two instructive articles by Will H. Coghill; and Dudley H. Norris has a stimulating dissertation on 'Molecular Forces in Flotation.'

There is also an excellent article by 'an occasional contributor' on the 'Effects of Soluble Components of Ore on Flotation,' discussing the cumulative effect on the efficiency of the circulating mill-water of soluble substances derived from the ore. Most of the facts given have been recognized for some time by practical workers but have not hitherto been published.

Contributions to the book describing actual working conditions on flotation mills that are in the producing stage are singularly scarce, but there are valuable notes on the principles of testing, the use and functions of various oils, and the disposal of flotation concentrate both by smelting and cyanidation. Regarding the latter point, which is dealt with in a careful and elaborate paper by Charles Butters and J. E. Clennell, the reader should not assume that the conclusions therein arrived at are necessarily applicable in general to all concentrates recovered by flotation because the writers seem to have chosen an unusually difficult ore for their tests, when regarded from the point of view of the cyanide process.

Among the most valuable chapters in the book are the two entitled 'Testing Ores for the Flotation Process,' by O. C. Ralston and Glenn L. Allen, wherein the writers explain in detail the laboratory testing of ores by the various methods and applications of flotation. This may be considered the latest and most reliable information published and the student just beginning experimental work in the process will find it invaluable. There is one department of the subject on which fuller information and explanation would have been welcome, and that is oils, their characteristics and uses. This deficiency is, however, made good to some extent in the chapter on 'Oils Used in the Flotation Process,' by another 'occasional contributor.'

The Editor is to be congratulated on having been able to elicit such a fund of varied and valuable information on the subject in spite of the tendency toward mystery and secrecy that has enveloped it for so long. It seems difficult to believe that the restrictions imposed by the Minerals Separation Co. against full and free discussion in the press and elsewhere are really rendered necessary by the exigencies of patent litigation, and the Editor of the MINING AND SCIENTIFIC PRESS in the course of his articles has repeatedly protested against the embargo this company has attempted to lay on useful knowledge. The futility of such a policy in the long run is evidenced by the appearance of this volume, which, although it comprises almost the only literature on the subject (with the exception of the book by Theodore J. Hoover published nearly four years ago) will no doubt be followed by others from time to time, to the great and lasting benefit of the individual metallurgist and the mining community at large.—E. M. H.

HYDRAULIC TABLES. By Joseph H. Harper. P. 192. Ill. D. Van Nostrand Co., New York. For sale by MINING AND SCIENTIFIC PRESS. Price, $2.

This book is designed to lighten the labors of the user of hydraulic formulae. The main body of the tables is divided into four parts, for flow in pipes, by D'Arcy's and by Kutter's formula, flow in open rectangular channels by Kutter's formula, flow in open trapezoidal channels by Bazin's and by Kutter's formula, and flow in egg-shaped conduits by Kutter's formula. The latter table is divided into three parts, for flow when running one-third full, two-thirds full, and full. All the tables are computed for several different conditions of roughness. Besides these tables there are others with considerable miscellaneous data, and also a discussion of the various formulae. An appendix contains a number of charts showing by means of curves, the different results obtained by the use of the different formulae.

INDUSTRIAL LEADERSHIP. By H. L. Gantt. P. 128. Ill. Yale University Press, New Haven, 1916. For sale by MINING AND SCIENTIFIC PRESS. Price, $1.

The five lectures comprising this book were heard by the senior class of the Sheffield Scientific School in 1915. The methods of industrial leadership are based on the system of scientific management evolved by Taylor, with whom the anthor was a co-worker; the chief doctrine of this school is that efficient management of labor increases profits and wages.

A novel point brought out is that an impartial study of the Lawrence strike showed that the labor leaders had a much better understanding of the problems involved than the employers, and that no permanent industrial peace can be hoped for until the employers are better educated. The great profits of the Ford automobile are held to disprove the old theory that great profit can only be had by high prices. A fault of the book is the failure to consider the strennous objections of the trade unions to scientific management.

THE CANADIAN MINING MANUAL FOR 1915. Edited by Reginald E. Hore, editor of the *Canadian Mining Journal*. P. 406. Ill. Published by Mines Publishing Co., 263 Adelaide St., W. Toronto. Can be obtained through the MINING AND SCIENTIFIC PRESS. Price, $2.

The editor states in a preface to Canadian readers that "one of the main objects of the publication of this book is to carry into other countries reliable information concerning the minerals and mines of Canada." The total mineral production of the Dominion in 1915 was $138,513,750, of which metallic products were $77,046,082; the similarity in the relative importance of the productions of nickel, gold, copper, and silver is noteworthy; nickel was $20,423,348; gold $18,936,971; copper $17,726,307; silver $14,088,397. Among the non-metallic products, asbestos was $3,491,450; coal $31,957,757; pyrites $1,028,678. The chapter on Canada in general is contributed by John McLeish, chief of the Division of Mineral Resources and Statistics at Ottawa; the chapter on Quebec by Theo. C. Denis, superintendent of mines for that province; the chapter on Ontario by T. W. Gibson, deputy minister of mines at Toronto; J. T. Sterling writes on mining in Alberta; and F. W. Gray on the coal trade of Nova Scotia. Of most valuable interest is the latter half of the hook, devoted to an alphabetical list of mining companies operating in Canada, with a brief description of each, giving address of the head office, situation of the mine, production and treatment of the ore, names of the officers and staff, and other pertinent details when the importance of the operation warrants it. The companies listed include everything in mining from the Atlantic Grindstone Co. of Nova Scotia to the Yukon Gold Co. of the Yukon. The book is more carefully edited than is nsual with publications embracing such a variety of information, and Mr. Hore is to be congratulated on a difficult job well done.

COMPANY REPORTS

MASS CONSOLIDATED COPPER CO.

Results at the Mass mine in Michigan in 1915 were much better than in the previous year. Cash assets increased $167,473. Development covered 4728 ft. Reserves are up to the normal quantity. The mill was improved and added to. Seven lodes contributed to the output. The mill treated 323,335 tons of ore, yielding 4,638,452 lb. refined copper, equal to 14.35 lb. per ton.

DALY-JUDGE MINING CO.

The report of O. N. Friendly, general superintendent of this Park City, Utah, company, to the general manager, G. W. Lambourne, covers the year 1915.

Development on three veins totaled 12,017 ft. to a depth of 1600 ft. The underground equipment and haulageways were considerably improved. An electric-hoist of 2500-ft. capacity, at 2200 ft. per min., is now being installed. A steel head-frame was erected. The mine was never more encouraging as to prospects for ore.

Crude ore sold amounted to 5809 tons, worth $23.93 per ton. The mill treated, by water concentration and oil flotation, 63,935 tons, yielding 10,828 tons of lead and 7169 tons of zinc concentrates. The output was 644,935 oz. silver, 642 oz. gold, 10,954,273 lb. lead, 9,775,097 lb. zinc, and 2,984,875 lb. copper, sold for $1,041,414. Dividends (6) amounted to $300,000. The balance is $678,907.

HOMESTAKE MINING CO.

The report of this well-known company, operating in South Dakota, covers the past year. As has been the custom in the past, the remarks of the new superintendent, Richard Blackstone, are brief, as the following will show:

"Operations at the mine and mills of the company, for the calendar year 1915, have been continuous. The erection of the new equipment [described from time to time by our correspondent at Deadwood.—EDITOR] has been about completed and will soon be in operation. The Pocahontas mill has been completely re-bnilt during the year. One-half of the Amicus mill has been re-built and rapid progress is being made toward its completion. These repairs were made with no material stoppage of milling capacity. The Columbia ditch has been re-built with permanent vitrified pipe. The dead-work, or development in the mine, has been carried on without interruption, having in view the outlining of areas of new ore-bodies and determination of the value of the same. During the year, there was excavated 1001 ft. of raises and 17,114 ft. of drifts. Preparations have been completed for sinking the Ellison shaft to the 2000-ft. level. The mine and the reduction plants are in first-class condition. The measured ore reserves are large and sufficient to supply the mills for many years."

During 1915 there was treated 1,573,822 tons of ore, realizing an average of $4.08482 per ton. The revenue from 246 bars of bullion was $6,428,787. Sale of wolframite netted $19,237. Including $897,596 brought forward from 1914, and sundry income, the total revenue was $7,423,379.

Some of the larger expense items were as follows: operation of mills, $381,701; operation of shafts, $369,355; mining, $2,050,151; machine-shop, $102,367; blacksmith-shop, $69,413; foundry, $96,741; cyanidation, $302,622; taxes $232,967; water, $113,623; general expense, $115,089; central steam plant, $161,947; and hospital and recreation hall charges, $62,369. The service rendered by the blacksmith-shop, foundry, and machine-ship was charged to mine and mill accounts, and is included therein.

Dividends totaled $2,210,208 on 251,160 shares. The balance to profit and loss account was $1,032,933. Costs, including everything, totaled $2.6561 per ton.

RECENT PUBLICATIONS

Laboratory Tests of a Consolidation Locomotive. By E. C. Schmidt, J. M. Snodgrass, and R. B. Keller. Bulletin 82. P. 129. Illustrated. University of Illinois Engineering Experiment Station, Urbana, 1915. Price, 65 cents. Notes of value to railroad men.

Wyoming and McDowell Counties, West Virginia. By Ray V. Hennen and Robert M. Gawthorp. P. 783. Ill., maps, index. West Virginia Geological Survey. Morgantown, 1915. This detailed county report covers one of the principal areas of the great Pocahontas or smokeless coalfields of West Virginia, giving a complete account of each coal bed, with analyses, estimates of unmined tonnage, and topographic and structural maps showing the elevation, dip, and strike of the principal coal beds, including the famous No. 3 Pocahontas, covering the Counties of Wyoming and McDowell, the latter leading every other county in this State in the production of coal of the highest grade by several million tons annually. Price, with case of maps, delivery charges paid by the Survey, $2.50, but for combination price with other publications, see general circular of publications. Extra copies of geologic maps, $1 each, and of the topographic map, 50 cents each.

Department of Mines, Ottawa, Canada, 1915:

Production of Coal and Coke in 1914. P. 39. A total of 27,571 men mined 13,637,529 tons of coal worth $2.15 per ton. The coke output was 1,015,253 tons.

Production of Iron and Steel in 1914. P. 35. The pig-iron made was worth $10,002,856.

Copper Deposits of the Eastern Townships of Quebec. By J. Austen Bancroft. P. 295. Ill., map, index. Department of Mines, Quebec, 1915. An interesting investigation into a number of deposits, some of which might develop into fair producers.

Summary Report of the Mines Branch of the Department of Mines for 1914. P. 232. Ill., maps, charts, index.

A lot of useful data is contained in this bulletin.

Production of Cement, Lime, Clay Products, Stone, and Other Structural Materials in Canada in 1914. By John McLeish. P. 60.

The total value was $26,009,227, a decrease of 15.5 per cent.

U. S. Geological Survey, Washington, D. C., 1915:

Antimony, Arsenic, Bismuth, Selenium, and Tellurium in 1914. By Frank L. Hess. P. 31.

Cobalt, Molybdenum, Nickel, Tin, Titanium, Tungsten, Radium, Uranium, and Vanadium in 1914. By Frank L. Hess. P. 24.

Mineral Production of the United States in 1914. A summary. By H. D. McCaskey. P. 69. Chart.

Some useful information is contained in these bulletins.

A Reconnaissance for Phosphate in the Salt River Range, Wyoming. By G. R. Mansfield. Bulletin 620-O. P. 19. Maps.

Geology and Oil Prospects of Cuyama Valley, California. By Walter A. English. Bulletin 621-M. P. 25. Maps.

Gasoline. Letter from the Secretary of the Interior, transmitting certain information, in response to a Senate resolution of January 5, 1916, relative to the production, consumption, and price of gasoline. P. 27. Chart.

Gasoline production last year was 41,600,000 bbl., of which 6,500,000 bbl. was exported, increases of 6,685,000 bbl. and 1,500,000 bbl. respectively. There were practically no stocks at the beginning of 1916, against 2,000,000 bbl. a year ago. The big rise in price can be traced to causes related to supply and demand.

INDUSTRIAL NOTES

E. P. Worden, formerly of Fred M. Prescott Steam Pump Works, Milwaukee, has been appointed chief engineer for Henry R. Worthington, Harrison, New Jersey.

E. C. Reybold, Jr., for a number of years connected with the Hendrie & Bolthoff Mfg. & Supply Co. of Denver, is now with the Dorr Cyanide Machinery Co., Denver, being secretary of this company.

P. P. Bourne, formerly chief engineer of Blake & Knowles Steam Pump Works, East Cambridge, Massachusetts, is again associated with the International Steam Pump Co. in connection with special engineering work, at the main office, 115 Broadway, New York.

The Denver Quartz Mill & Crusher Co., Denver, has just received a repeat order from the Luckie 2 Tungsten Co., at Boulder, Colo., for a No. 1 Denver quartz mill. The constantly increasing price of tungsten is causing a heavier output from the mines near the Luckie 2's mill, and necessitates this additional equipment. Last December the company purchased a No. 1 quartz mill.

The Bunker Hill & Sullivan Mining & Concentrating Co. recently awarded a contract to the Traylor Engineering & Manufacturing Co. of Allentown, Pennsylvania, for three silver-lead blast-furnaces, 48 in. wide by 180 in. long at the tuyeres, having a smelting-column of approximately 20 ft. 6 in. These furnaces are equipped with a double tier of jackets, the lower ones being provided with Traylor patented welded tuyeres. This contract was awarded the Traylor company solely on the superior design of its water-jackets.

The present expedition of the United States Army into Mexico brings to light an interesting condition governing preparedness in our ability to quickly mobilize. The White Co. furnished 28 motor-trucks together with volunteer drivers and mechanics on 24 hours' notice, taking the trucks from stock of those regularly sold for mining work. These form the first regular Truck Company of the Army. In the event of an additional call, many similar trucks could be furnished and those in use in mining districts might be requisitioned.

Electric mine-hoists are described and illustrated in a splendidly prepared bulletin, No. 15, of the Lidgerwood Manufacturing Co., New York. The publication is 9 by 12 in., covering 30 pages of heavy smooth paper. Since 1890 the firm has been developing these hoists of all sizes, with a view to safety and continuous operation. The strain on hoist-motors is of great importance, therefore they have been carefully studied. The bulletin shows single and double hoists for all purposes, a gathering hoist, indicators, sheaves, and cages. A page is devoted to data required for estimating on electric mine-hoists.

Bulletins 154 and 110 have just been issued by the A. S. Cameron Steam Pump Works, 11 Broadway, New York. The former is devoted to Cameron centrifugal pumps. Sectional views are used to illustrate both the single and double-suction open-impeller types, and the booklet gives tables of capacities, speeds and horse-powers. The other publication covers the Cameron line of duplex-pumps, including both piston and plunger types, with single and compound steam-cylinders for general service, boiler-feeding, tank-service, water-works, hydraulic-elevators, automatic-pumps and receivers, brewery, quarry and mining work. The catalogue is well illustrated, and also contains tables of sizes and capacities. Copies are free on request.

EDITORIAL

T. A. RICKARD, Editor

ANTIMONY continues in demand. In San Francisco $2.50 per unit is offered for 40% ore, the price rising to $3 per unit for over 60% ore.

CARRANZA paper currency is quoted at 2 cents on the dollar. This indicates the improbability of war with anybody whose dollar is quoted at 100 cents.

FULLY a dozen new magnesite kilns have been built in California during the last two months. This State possesses deposits of magnesite yielding both the more and the less fusible varieties required for furnace-lining and tiling respectively.

TESTS made during 1915 on a working scale (4407 tons) in the experimental mill of the Copper Queen Consolidated Mining Company have demonstrated that rock containing 1.3% of copper can be called 'ore' and it is probable that 1% material can be exploited profitably, by aid of water-concentration and flotation.

ACCORDING to the *Metal Bulletin*, published in London, arrangements have been completed, with the approval of the British government, for the complete and perpetual elimination of the German shareholdings in the firm of Henry R. Merton & Co. Mr. Henry Gardner becomes head of the newly constituted business, which is now entirely divorced from the Frankfurt Metallgesellschaft.

NOT long ago we commented on the fact that the Butte & Superior Copper Company did not produce copper, but zinc. We note now that a circular has been sent to the stockholders proposing to change the name. Whether 'zinc' is to be substituted for 'copper,' or whether the company will give itself a chance of digging gold, tungsten, or some other good thing without further nominal impropriety is not stated.

QUICKSILVER is being won from alluvial deposits on the Klamath river, in Siskiyou county, the cinnabar ore from the sluices containing 4% mercury. The high price has prompted re-treatment of dumps at old lode mines in California, like the Napa Consolidated, where stuff containing only 0.12 or ¼% is being sluiced and concentrated on Deister roughing tables. The New Idria also is using water concentration.

NEW YORK is taking from Boston much of its former importance as a centre of mining speculation. United States Smelting has now found an official market on the New York Exchange, following in the recent wake of American Zinc, Butte & Superior, Alaska Gold, and Greene-Cananea. Seven mining companies, aggregating over 3,000,000 shares have thus been added to the New York list, at the expense of Boston. The total dealings during a couple of months in three of these stocks on Wall Street has been equal to half of all the trading on the Boston exchange. Centralization is convenient, but we are sorry to see Boston lose its importance as a centre for the business of mining.

DISEASE is not a pleasant subject but occasional discussion of it is necessary in order to promote sanitation. In this issue we publish an article by Mr. Rush M. Hess on a disease to which miners appear to be particularly subject, namely, hookworm. We believe that the information given by Mr. Hess in regard to the detection and prevention of the malady will prove of the greatest practical benefit to miners. We urge every superintendent to read the article carefully, for it affects the welfare of his men and their efficiency as workers.

TO what proportion the business of patenting has grown is made clear by the report of the Commissioner of Patents for the year 1915. This states that $2,022,141 was received for applications and $211,045 for copies, the total receipts being $2,290,773, as against a total expenditure of $2,053,442, leaving a surplus of $237,331. The total surplus earnings of the Patent Office now deposited with the Treasury of the United States amounted to $7,785,506 on December 31, 1915. During last year 40,321 patents were issued to citizens of this country and 4334 to residents in foreign countries. Applications have increased from 21,638 in 1875 to 70,069 in 1915, but the maximum to date was recorded in 1912, when the number was 70,976. Since 1871 the United States government has granted 1,012,595 patents and the rest of the so-called civilized world has granted 1,293,064, from which it may be inferred that patenting is a luxury highly developed in this country.

CORDIAL support should be given to the effort being made by the Chamber of Commerce of the United States to enlist public interest in commercial preparedness for the intensified competition for trade in foreign markets that is sure to be one of the consequences of the War. Additional commercial attachés and trade commissioners are demanded, but we hope that the question of quality will not be subordinated to quantity. Men of unusual intelligence and adequate linguistic versatility are required for such purposes. They are necessary as

collectors of information and scouts for markets. In London and Paris an earnest effort is being made to organize for post-bellum trade. President Wilson recognizes the timeliness of organized effort, for, when addressing Congress in December, he referred to "the day of readjustment and recuperation" that must follow the European war, and mentioned "the necessary instrumentalities of information." Let us prove that a democracy can organize itself, for peace at least, as well as any autocracy.

CORNISH mining has been heartened by the discovery of a rich ore-shoot in the East Pool mine. This old property was re-opened on the initiative of Mr. W. J. Loring, of the firm of Bewick, Moreing & Co., guided by a geological examination made by Mr. J. Malcolm Maclaren. The discovery was not due to mere luck, but to a careful study of a series of faults and logical reasoning therefrom. It is only fair to add that Mr. Loring's attention to East Pool was drawn by Mr. James M. Holman, of Holman Bros. at Camborne, whose drills finally broke a way to the orebody.

DISCUSSION is an important feature of this issue. Our honored friend, Mr. E. P. Mathewson, the manager of the Anaconda smelter, offers valuable comment on our recent remarks concerning the training of mining engineers. He deprecates excessive specialization. Evidently our suggestion on the subject was misunderstood; we advocate the study of a specialty only after a broad training has been obtained, and not as a substitute for the general preparedness preceding a professional career. Mr. John B. Simmons describes an advanced scheme of prospecting, the ingenuity of which will be appreciated even if it does not meet with immediate endorsement. Mr. Herbert Lang, a veteran metallurgist and an inventor not unfamiliar with the vagaries of the Patent-Office, offers some pertinent remarks on a subject that is of particular interest just now. He is followed by Mr. H. G. Prost, a patent attorney, who supplements his interesting letter appearing in our issue of March 18. To Mr. John Allingham, an experienced millman, we are indebted for a short cut in estimating the tonnage of slime.

AMONG the articles recently declined by us, as being unsuitable for publication, was one explaining 'Why people buy mining stock,' in which the chief argument for buying such stock was based on the dividends paid by mining companies. The author, of course, was able to present imposing totals, showing how much more than the original capital of a selected number of rich mining companies had been returned to shareholders. Among others, he quoted the Comstock as having distributed enormous profits. And all this, it may be assumed quite fairly, was intended to whet public appetite for a puling wild-cat in Nevada or Arizona. The mining industry offers excellent chances for the use of money in speculation, but this sort of 'guff' has outworn its day. The return on nominal capital affords no criterion of the amount of money won or lost in the purchase of stock in a particular mine. If the public could buy into good mines on the ground-floor, the record would be flattering indeed, but, as a matter of fact, much money has been transferred from the guileless many to the guileful few by means of some of the richest mines in the world, simply because the innocent and ignorant bought stock when the mine was enormously over-valued. As for the Comstock, the chicanery and gambling connected with mining companies operating at Virginia City did much more harm than good to the industry. Whether a mine will enrich or impoverish the buyer of stock, in a company controlling it, depends upon the particular stage in its development at which the shares are bought.

Geology of Tonopah

The silver-mining district of Tonopah, in Nevada, is one of the few localities in which the relationship of mineral deposition to structural geology has been diagnosed with such definiteness as to aid the mine superintendent in his search for ore. The diagnosis will always be associated with the name of J. E. Spurr, for to this geologist we owe the first clear analysis of the petrographic conditions and to him also we are indebted for several contributions of knowledge on a matter of vital interest to the miner. In a recent number of *Economic Geology* he reviews the evidence gathered at successive periods from 1902 to 1915. We have read this review with keen appreciation, for in his outline of the development of ideas on the basis of cumulative observation and his frank acknowledgment of minor errors of inference he writes in the true spirit of science, which is to recognize the logic of facts whether the heavens fall or the earth is disrupted underfoot. On the whole, even his first study of the district has been confirmed by actual mining, which has demonstrated that the most productive veins are in a trachyte that was covered or intruded by a number of later eruptives. The names of the various rocks have been changed more than once during the past 12 years in such a way as to perplex those interested in the local geology, but that has been the case in many other mining districts, and must be accounted one of the penalities of scientific progress. Both the effusive volcanic rocks and the ore deposition that makes them interesting belong to the Tertiary period. The oldest known rock in the locality of the mines and the one traversed by the richest veins is a trachytic flow, the lower portion of which is glassy and barren of ore. These older veins were formed in the trachyte before it was covered by later extrusions. After the trachytic eruption came several others at intervals, differentiated as andesite, rhyolite, and dacite, most of them followed by a period of vein-formation, but none of such economic importance as that which enriched the trachyte. Of the later veins the most interesting is associated with a sill of rhyolite that cuts through the trachyte and the older veins. Mr. Spurr regards the ore as a magmatic residuum closely associated in its origin with the alkaline-

silicious magmas from which these eruptive rocks were derived.

Two points must be noted. The first is that the vein formation and ore deposition took place at no great depth. Allowing for erosion and the successive accumulation of volcanic rocks, it is demonstrable that the depth at which the veins were formed did not exceed 2000 feet and that the oldest and richest orebodies came into existence at a time when the surface at that period was even nearer to the place of mineralization. Mr. Spurr regards mineralizing solutions as the end-products resulting from the differentiation of magma, so that distinct metal-groups may be deposited at different temperatures from solutions having the same source. According to him, veins characterized by the sulphides, tellurides, and selenides of silver, with the tellurides of gold, such as are found at Tonopah, are characteristic of a shallow depth, a Tertiary age, and a fine-textured or glassy volcanic rock. They belong to a period of comparatively low temperature and a place near the surface. The heat underground in this district is still remarkable, the water encountered in a deep drill-hole from the bottom of the Mizpah shaft showing a temperature of 108° F. This linking of variation in temperature and pressure with the deposition of recognizable groups of minerals is important. In advocating the theory, Mr. Spurr is following upon the idea, previously advanced by him, that relatively long-sustained temperatures at the critical point of precipitation for a given mineral group are necessary for the accumulation of an ore deposit of economic importance.

Another interesting feature is the penetration of thin dikes and tongues of intrusive lava appearing now as a glass. In places this lava had to pass through passages too narrow to admit even the smallest solid inclusions, which were filtered out. It would appear as if the pressure exerted by this liquid magma had sufficed to enlarge the opening into which it had been admitted. Thus Mr. Spurr concludes that although the quick chilling of the lava into glass indicates that the rocks penetrated were cold and inferentially at a shallow depth, yet the lava was able to lift several hundred feet of rock in order to make room for itself. In one case, that of the West End-MacNamara lode, it is inferred that a large flat-lying quartzose vein was formed by the creation of an opening that was filled with ore while it was being enlarged; that is, the silicious solutions exerted sufficient pressure, along an old line of weakness, to lift the overlying rocks and support them during the interval required for the crystallization of the quartz and its accompanying minerals. This is a bold bit of constructive imagination and should stimulate further research. Indeed, most of the ideas quoted above are in the nature of audacious theories, stimulating to observation but requiring verification before becoming acceptable as safe guides. It is to be noted that the relatively flat veins of the district do not reach the surface and so relief of pressure upward was not obtainable by the solutions that enriched them. The reasoning adopted by Mr. Spurr brings veins and dikes closer together, making them both the result of magmatic differentiation and invasion. Instead of thinking of such veins as the result of the corrosion of the walls of a fissure, we are asked to regard them as the filling of a crevasse, the opening of which is accompanied by up-welling solutions representing the residuum of magmatic segregation. They may be compared to the cracks in ice, which are filled by water as the crack advances.

These theoretical considerations may not seem to assist the search for ore, but, as a matter of fact, they stimulate study and give a point to research. At Tonopah they have prompted a great deal of careful investigation, not only by Mr. Spurr but by Messrs. J. A. Burgess, W. H. Grant, and George H. Garrey, besides several of the mine managers, notably Messrs. F. H. Bradshaw, John A. Kirchen, and John W. Chandler. The result has been not only to elucidate the structural geology of the district but to facilitate the search for ore, the distribution of which is dependent largely on structural conditions. For the early work at Tonopah the Geological Survey is responsible, for at that time Mr. Spurr was a member of the Survey, but his later investigations have been made on account of the Tonopah Mining Company, which Mr. Burgess also served as geologist. This company and others in the district have shown an enlightened appreciation of the aid that economic geology can give in actual mining operations, and to them is due no small measure of the credit for the knowledge thereby obtained, to the gain not of themselves only, or of the Tonopah district, but of the art of mining.

The Bunker Hill Smelter

In our issue of October 2, 1915, we stated that the Bunker Hill and Sullivan Mining and Concentrating Company intended to build a lead smelter. We are now able to announce that Kellogg has been selected as the site for this reduction works. The choice hovered for a time between several localities on Puget Sound, certain points on the lower reaches of the Columbia river, and the vicinity of the mine itself. In choosing the last the management had to decline a most friendly offer from Spokane as well as the allurements of tide-water, but the factor of railroad rates proved decisive. The rate from Kellogg to New York is established at $12 per ton for pig lead, and no unfriendly influence is likely to be able to enforce an increase. From Northport also the rate to New York is $12 per ton, but to this must be added $2.75 per ton on concentrate, of which two tons will yield one ton of pig lead, so that the total freight comes to $17.50. To Spokane the rate from the mine is $1.75 per ton of concentrate, equivalent to $3.50 per ton of lead, making the total from the mine to New York $15.50. To lower points on the Columbia river the freight is $3.50 per ton on concentrate, which again must be doubled to get at the equivalent in lead. The rate by the Panama Canal to New York is only $5, but to this $1 must be added for interest and insurance on

the long water-haul, so that the total is $13 per ton. Thus Kellogg offers an advantage. Moreover, it is the home of the company's mining and concentrating operations and offers every hospitality to further metallurgical reduction. The wages paid at Kellogg are higher than on the Coast, or down the river, but it is understood that the bonus now being paid to the miners on account of the high price of lead will not apply to smelter operatives. Hitherto the output has taken the form chiefly of various concentrates, which have been shipped to the East Helena and Selby smelters. It is proposed to treat at Kellogg such products as are not covered by existing contracts, that is, the lower grades and the higher grades of concentrates and the ores produced by subsidiary companies. The new smelter will be built on the Bingham and Giovetti ranches, just below the mine. It will consist of three blast-furnaces, each 48 by 180 inches at the tuyeres, and a roaster equipment comprising one Wedge furnace and four Dwight-Lloyd sintering machines. A sampling-mill, a bag-house, and a refinery for separating the precious metals will constitute other parts of the plant. The relations of such parts is made clear in the article describing the Selby lead smelter, which article, by a coincidence, appears on another page of this issue. The Kellogg smelter will employ 300 men and will have a capacity of 900 tons of charge, 80% of it lead ore, per diem. It has been designed by the firm of Bradley, Bruff & Labarthe. Construction will commence forthwith and the plant is expected to be completed in a year from date. The greater portion of the material and equipment has been ordered already. The concentrates and ores to be treated carry a high percentage of lead, and the iron is present chiefly as a carbonate, not a sulphide, so that the sulphur content will be low. Any danger of fume nuisance will be further prevented by use of a bag-house. Electric power will be supplied by the Washington Water Power & Light Company, which gets its energy from the Spokane river and Long lake in Washington. The smelter will be served by the Oregon-Washington Railroad & Navigation Company, which is a north-western subsidiary of the Oregon Short Line, tapping Huntington, Spokane, and Portland. It remains to add that another independent smelter, the one at Northport, on the Columbia river, at a point close to the boundary between British Columbia and the State of Washington, started to work under the management of Mr. Harry L. Day last month. As most of our readers are aware, Mr. Day until quite recently was the president of the Federal Mining & Smelting Company, a Guggenheim or American Smelting subsidiary. He controls the Hercules, Tamarack, and Chesapeake mines in the Canyon Creek district, also in the Coeur d'Alene region of Idaho and only 15 miles from Kellogg. The ore from these mines likewise used to go to East Helena and Selby. The Northport smelter has a capacity of 600 tons of charge, say, 480 tons of lead ore, in each case one-third of capacity being held in reserve. Mr. Day sends his lead bullion to the Pennsylvania Smelting Company, at Pittsburg, of which he obtained control recently, so that he is independent as to smelting, refining, and marketing. Undoubtedly the operations of these two independent smelting units, at Northport and Kellogg, will have an important bearing on the development of the Coeur d'Alene and encourage those mine operators in the Northwest that have complained, not without reason, of the excessive rates levied by the big smelting combinations.

The Selby Smelter

On another page we give a description of the smelting operations at Selby. San Francisco has reason to be proud of that metallurgical establishment. It has played a notable part in the mineral development of the Pacific Coast region. To it have come some of the earliest products of mining districts now famous. Jim Wardner, the pioneer of the Coeur d'Alene, came to Selby with his first shipment of ore and thus prepared a way for the long-continuing business between this smelter and the great Bunker Hill & Sullivan mine. Some of the first Utah lead ore also came to San Francisco, from the Emma mine. Before the railroad was available eastward, the Arizona lead product and the rich silver ore of the Silver King mine came to Selby. So did the early output of the Slocan district in British Columbia. In later years the development of Tonopah was assisted by the market offered by the Selby smelter for the siliceous silver ore of Nevada. Indeed, before a great system of railroads gave varied facilities for the shipment of the products of the mines, the fact that a lead smelter was in operation on the Bay became a decisive factor in promoting the development of the region tributary to San Francisco. Even today, despite the growth and variety of smelting facilities in the West, this establishment of the Selby company is no mean asset to the community. The photograph of the works, at the head of the article, is in itself suggestive, for the vessel seen alongside the smelter-wharf will suggest traffic overseas. A ship is ever the spur to imagination. To the smelter comes coke from Germany and Australia; concentrate from Korea and Mexico. From the smelter goes lead to New York, silver to Hongkong, and gold to the Mint. The white paint made from its lead is laid on the battleships at the Mare Island navy-yard and the bluestone derived from its refinery aids the agriculture of California, while the lead shot and bullets manufactured at Selby fly far, after ducks and after game of a less innocent kind. Indeed, the variety of products and by-products is remarkable. For instance, besides producing lead, silver, and gold, each in ingot form, this establishment makes sheet-lead, pipe, traps, and a variety of minor lead articles, for instance, the buttons employed for weighting women's dresses and the 'sinkers' used by fishermen. A smelter like this is an industrial organism of great interest; in itself it illustrates the diversity of use to which mineral products are put and suggests the growing complexity of the scheme of living we call civilization—concerning which in the year 1916 the less said the better.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Training of Mining Engineers

The Editor:

Sir—Referring to your editorial on this subject in your issue of March 11, I beg to offer the following.

First, I agree with you in your "cheerful negative to the first question." I also endorse your remarks down to the point where you suggest specialization in teaching engineering, but here I take a strong exception to your proposal.

During the last thirty years, it has been my good fortune to have had to do with training of more young engineers, fresh from college, than perhaps any other man in the profession in the United States; and I have found that those who have been most successful are those who have had the least specialization in their college training. My belief is that the duties of the technical college, so far as engineering instruction is concerned, should be confined to the furnishing of a course of general studies that would train the mind of the student to think for himself, should ground him well in mathematics, physics, chemistry, with a short course in assaying, and enough surveying to make him familiar with the instruments in common use. In so far as metallurgy is concerned, he should, if possible, be taken to plants where the principal types of machinery and metallurgical apparatus are in use, and be shown their purposes without being allowed to operate them. A similar course of demonstration should be made with mining students, and, wherever possible, the students should be compelled to take practical work in some line of engineering during the summer vacation.

In addition to the studies mentioned above—as many students come to the technical college with insufficient grounding in the "three Rs"—the examination for entrance should be made stiff enough to insure a proper course of preparation. In connection with the college work there should be some instruction in accounting, and in the writing of readable and logical reports; but by all means cut down the specialization in engineering colleges to the minimum. It must be borne in mind that the young men entering such colleges have, in most cases, no idea what their future in life will be; and when they graduate they are, at best, only prepared to enter upon the study of the engineering profession. They have to seek employment, and if only trained along narrow lines they cannot get, at the outset, just what they want. Many instances occur to me where men took the civil engineering course in college and became mechanical engineers in practice, and *vice versa*; also where men had specialized in mining and had, in actual life-work, become metallurgists.

Let us suppose a man specializes in flotation—according to your suggestion—and he goes out into the world landing at a place like Butte, and finds all the jobs in the flotation plants filled, he naturally takes the first job that offers—it may be that of a 'mucker' in one of the mines. If he has the right stuff in him, he will stick to that job until he becomes shift-boss and from there his career will gradually be upward, but he will never again think of flotation.

Another thing to be remembered is that the teaching staff in our colleges cannot be expected to be in a position to give the special training outlined in your editorial. Again I say, cut down specialization, but give the student the best possible ground-work, so that he can think, act, and study on his own account, and be prepared to tackle any problem coming under the heading of engineering.

E. P. Mathewson.

Anaconda, March 15.

How to Prospect

The Editor:

Sir—Apropos to the symposium on prospecting, which ran in the pages of your paper for a period last year, I beg leave to offer the following:

What is the matter with prospecting? It is easier to recognize that there is something wrong than to be able to offer helpful constructive criticism on why it is so, or to offer a suitable remedy for the condition.

In the last decade I have witnessed several periods of mining activity in Nevada, the State that, from its expanse, its undoubted mineral character, and the nakedness of its rock exposures, would seem to offer the best possible field for prospecting. Yet the reward in new discoveries, barring those made almost simultaneously in several parts of the State immediately following the finding of Tonopah, have, with a few minor exceptions, been pitifully few and of no great importance. One can hardly refrain from asking, why?

While crossing the desert recently, I chanced to doze reflectively in a comfortable arm-chair in the observation car of an overland train. Mirages danced playfully across the alkali flats in the heated afternoon sunshine. With no directing will, the mind responded to the atmosphere and soon a mirage clearly visualized engrossed my attention. Across the horizon to the south I saw a moving object—a house on wheels moving down the middle

of the valley. The 'house' was attended by objects of lesser size, also mobile. Closer inspection revealed the objects to be a first-class prospecting expedition, consisting of a large auto truck carrying under an enlarged covering a complete assay-office, with rock-breakers and an equipment for making rough, wet and dry, concentration tests of ores or of gravels, and with the camp equipment to shelter and feed a party of half a dozen men. The lesser objects proved to be small autos, 'Fords' if you will, capable of running up the side-draws and canyons that debauched upon the valley every few miles in traversing its course. These little machines, each manned by one or two capable prospectors, were the 'business getters,' the means of gathering the rock samples expeditiously and in quantity and the gravels from the draws, for immediate testing at the assay 'office' moving down the middle of the valley.

I saw in this vision a solution of many of the most serious obstacles to successful prospecting, the obvious consideration of those at all informed in the matter. The principal advantage of attacking the problem in force and with such an equipment is that an expedition like this can make use of the combined services of the trained technical man and the 'old time' prospector, can at the same time cover more real ground in a systematic way at a less expense per square mile, can test samples immediately with greater certainty and at smaller expense, and finally can spend $10 in a collective way that will produce the results gained by spending $20 in the hap-hazard fashion of two decades ago. Thus equipped we are not trying to fight today's battles with yesterday's tools; those served and passed a generation ago in scenes and fields less combed over, aye, even virgin. Every valuable vein discovered and every mine found, unless it be of a new type such as the low-grade porphyry copper deposits of recent exploitation, leaves one fewer deposit undiscovered, and makes the subsequent finding of valuable deposits less a matter of chance and more a matter of systematic and scientific search. Possibly with such an equipment other new types of mines may be uncovered. It can be said without cavil that there would be fewer 'bench-warmers' around the principal hotels in Western cities awaiting the appearance of the 'expert' for some mysterious Eastern syndicate, for the purpose of foisting upon said expert an alleged mine that has been bandied about for 20 years, if the expert could but prevail upon his Eastern syndicate to equip him with a modern prospecting outfit as above described. Mines are found as well as made, contrary to the flippant current observation. If the expert changed his methods somewhat, he might also change the recurring annual report to his directors that he had "in the year just past turned down some 365 mines and near-mines," had spent $100,000 upon his staff in the quest, but had found not a single prospect worth considering. To my personal knowledge in the past two years two splendid mines that had been presented on desirable terms to such an expert were passed over for want of careful and intelligent consideration, mainly because the consideration of the other 363 prospects confused his better judgment. In a word, to my mind, there is nothing the matter with prospecting, the lapses are in the men and in their means and methods; the times and conditions and requirements have changed, and so must the methods of attacking the problem if results are to be obtained.

JOHN B. SIMMONS.

San Francisco, March 8.

The Patent Game

The Editor:

Sir—Your somewhat optimistic view of the workings of the Patent Office at Washington, in the issue of January 29, almost reconciles me to the fate of being an inventor. My feelings, however, are hardly as hopeful as yours. I fear the patent machinery of our Government has seen its best days and will have to be rebuilt, at least, if not scrapped bodily. You instance chiefly the evil of litigation, so unavoidable in bringing new inventions into use; but this, in my opinion, is but one of the evils that the times have brought. The Patent Office, we are told, was instituted with the statesmanlike and philanthropic object of stimulating invention, benefiting inventors, and subserving the interests of the general public. The results at first were excellent, no doubt. A Yankee who had found a new and improved way of making a wooden spool, wooden nutmegs, or what not, could at that time go ahead and construct his machinery and shop, with his own hands perhaps, and then proceed in peace and quietness to enjoy the fruit of the honest labor of his brain and hands. But times and customs have changed; wooden nutmegs have fallen under Dr. Wiley's displeasure; spools are no longer made in small shops a dozen at a time, but in great factories where millions are turned out in a day, under the domination of a soulless corporation. The Yankee's small triumph has been swallowed up in the general progress of the age, and the inventor has become a part of the controlling trust, or he has been retired to obscurity by its influence. His patents are only valuable for keeping somebody else out of the business. The same tendencies have overtaken the Patent Office also, and it has become a sort of industrial concern, in which, I fear, quality of work is often sacrificed to quantity. As long as the issued patents were counted by hundreds or by thousands and the individual issues could be kept comfortably within the recollection of a few men, the quality was good and the output satisfactory; but when as now it has mounted to millions, and a highly specialized and numerous staff of examiners is employed, many objections have to be made as to the quality of the work. It is hardly too much to say that the Office has fallen perceptibly away from its former efficiency and is approaching a condition in which it will totally fail to stimulate inventors, to benefit the general public, or to reward anybody whatever, except the flourishing class of patent attorneys who, if one may judge from the multiplicity of their advertisements, make a pretty good thing of it.

Adverse impressions like these are strengthened by an inspection of the Patent Office *Gazette*, an enormous publication, as unintelligible as it is bulky, which is issued once a week, as a kind of compendium of its labors. If the reader be skilled in translating 'patentese,' the jargon adopted by the Office to conceal its thoughts, he will come to agree with me that the patent powers of our country deal mainly in trifles, its output consisting almost exclusively of the merest threads and patches of invention, but done up in packages that to a tyro look like the real thing.

Why is it that the greater part—I almost said all—of the output of the Patent Office is the veriest rubbish? Have our inventors degenerated into snappers-up of unconsidered trifles, and become mere grubbers after shreds of invention and discovery, searching as searches the industrious fowl among rubbish heaps for the crumbs of former feasts? How does it happen that in the whole weekly deluge there is so little worth mentioning, let alone worth patenting? The answer may be as follows:

You can easily patent an invention for doing what nobody wants to do, or for doing in an inferior manner what is already better done; but difficulty arises when you seek to secure a real improvement, or a reasonably complete patent. The Patent Office, by virtue of its duties and responsibilities, has become afraid of big things, but revels in small ones. Nothing is too minute and insignificant to patent. The Office moves along certain fixed paths that lead to the light in only one direction. Your invention may be new, but the chances are that it is old. To find out you must make a formal application for patent on a thing that is, perhaps, forty years old. There is no *index rerum* in the Patent Office —it knows no way of facilitating an inquiry. With the aid of your attorney (necessary unless you would fall a victim to the Examiner's satire) you prepare an application at a cost of $30 up, and having forwarded it, you sit down to wait four or six months, to ascertain what the Office should have been prepared to tell you promptly, namely, the state of the art; which means, what fellows have blundered onto the ground before you. The Office eventually replies. You are informed that your application is rejected as lacking novelty, and you are furnished a list of, say, 20 patents of this and other countries covering, in the opinion of the Examiner, the ground ahead. Now let us see how this affects the inventor. If you are an old hand at the business you would have expected something of this kind. The fair form of the inventor's offspring is totally eviscerated. One man has the heart, another the liver, another the lights, while to another has been given the skeleton. The inventor is in despair. But wait, says the attorney: here is a bit of skin that everybody has overlooked; we can patch it up a little and maybe hang a valid claim on it. But what's the use, says the inventor; nobody would buy skin. Well, the money having been paid over and the Patent Office moved to action once, the rest seems easy; the application is narrowed down to conform to the state of the art, and eventually a kind of patent is got. Everything becomes easy after the Examiner has pared things down enough. If a man really wants or needs a patent of this kind he can get it by hanging on, for it is strongly suspected that the people at Washington sometimes give one to a man to get rid of him. I can understand this, but I cannot understand how a man can be so lacking in sense as to accept it.

Patent seeking has now degenerated into a game in which skill in framing the papers counts for more than the inventor's ingenuity. As the value of your prospective patent rests upon the validity and scope of the final claims, your lawyer has come to play too great a part in the adjudication. He is pitted against the Examiner, and if he proves lazy, incompetent, or unfaithful, you are lost. It doesn't matter what you have devised, your fortunes are in the hands of two men who naturally are concerned solely with getting rid of you. What the inventor loses through ignorance of the patent game, added to what he loses by the carelessness of his attorney, plus whatever the Examiner can deprive him of, leave what we find in the *Gazette*: a poor return for so much brain fag. It is no wonder that so few patents are worth the paper they are printed on. I don't imagine that one patent in a hundred pays the inventor, nor that one in a thousand ever benefits the general public, which, by the way, seems to have been lost sight of in the scramble, and perhaps it is as well, for whatever good could come to it is altogether too remote and fanciful to consider. Why not refrain from such a losing game? Why, when we discover in an old machine a new hole to put a screw in, or when we invent a new means of stirring up the mud in a cyanide-tank, why cannot we go quietly to work without any fuss, and do it, without appealing to the Patent Office, at no end of expense to ourselves and annoyance to them, for protection for our insignificant little alterations and so-called improvements? This question brings us to the nub of the whole argument.

The number of patents is so great and their scope so uncertain, that any projected improvement in construction is almost certain to run afoul of vested rights, to our cost and discomfiture. It is almost inevitable that among the million and more of American patents there is at least one upon which we would unwittingly infringe. It appears then that the American law acts to protect the inventors of one generation against the next; and, as often happens, enable those who have taken out patents, which they have suffered to remain inactive, to levy tribute on people who really wish to use their inventions. This, in my opinion, is the worst feature of our system. The engineer or builder who may desire to put in use improvements that he has devised, is debarred from so doing because of the existence of possible prior inventors, the majority of whom have never put their ideas into practice. I submit that this is an undesirable condition, none the less because it was foreseen by the framers of the law. The best recourse in this case is to have a search made of all the existing patents, which will generally indicate where the danger lies. Some patents

may have to be bought outright, some royalties may have to be paid, but in any event a good deal of time and some money is well expended to clear the road ahead. From the point of view of the engineer intent upon building new things, the situation is sufficiently annoying, and some of them go so far as to characterize patents in general as an intolerable nuisance. They hold that the whole crop of patents should be canceled and utterly done away with. Personally, I would not hesitate to cast my bushel or so of patents into the discard along with the rest, if by so doing I could get a free hand in designing things as I wish, free from interference from others.

It is not, of course, to be expected that the policy of our Government, so long persisted in, will be altered in any material particular, since the general public has not yet become dissatisfied with the workings of the Patent Office. But in the future when the rapidly expanding files have grown, as they inevitably will, to an unmanageable bulk, some action will have to be taken in the interests of inventors and the public alike. I should think that some useful editing might be done, making existing records more accessible and more intelligible. You have remarked on the difficulties that the courts meet in endeavoring to adjust rival claims, and upon the tendency of patentees to obscure and extenuate their claims. Judicious pruning on the part of properly qualified officials, I should think, would go a long way to ameliorating such conditions. The least the authorities should do is to curb the verbal ingenuity of the patent attorneys, many of whom take delight in spinning out claims to a wholly unnecessary extent, adding largely to the difficulties of everyone whose business brings him to deal with such things. As it stands now, no one can fully comprehend the scope of even an ordinary patent —I doubt, if in the majority of cases, the inventor himself knows precisely what he has patented, and I am sure the public does not. Some patents have as many as 40 or 50 claims, couched generally in unfamiliar language and presenting the subject in a manner entirely strange even to the inventor, who of all men may be least likely to understand it in its new phase. I pity the judge who has to wade through such a mess of claptrap. I think, on the whole, that the Government might change its policy profitably, gradually if need be, to the practice in Germany, granting few patents and only after strict scrutiny, then standing behind each patent so as to make it valid without the seasoning process of court action that seems inescapable with us.

HERBERT LANG.

Oakland, February 26.

The Scope of a Patent

The Editor:

Sir—The matter of interpreting the scope of a patent claim is so generally misunderstood, and unfortunately in many instances through misinformation, that a great service to the inventor would be performed if he could be given only a superficial knowledge of the subject. This misinformation is used to work a great injustice to the inventor, since he misinterprets the scope of his claim; bases his calculations and expends his money on the false assumption that he has a broad claim which covers his invention, and finally comes to grief.

The matter is a simple one, yet it is often difficult for an inventor to understand it. Assume that a man has invented an apparatus which in its complete form comprises a combination of six elements. A narrow claim on the invention will include all six of the elements and the inventor, upon reading this claim and finding all six elements contained therein, believes that his invention is fully covered. The claim, however, only covers the combination of elements contained therein, or their equivalents, and in order that the claim be infringed, the infringing device must contain the six elements. If it contains only five of the elements, it is not an infringement, and it is not a very difficult matter in many instances to dispense with the sixth element.

A claim only covers the combination of elements set forth therein or their equivalents and does not cover an apparatus that does not embody all of the elements of the claim.

San Francisco, March 23.

Estimating Slime

The Editor:

Sir—In estimating slime tonnage the following may be useful, more especially to those who appreciate short cuts:

Pounds of dry slime per cu. ft. of pulp =

$$\frac{\text{weight of 1 cu. ft. pulp} - 62.5}{x}$$

$$x = \frac{\text{sp. gravity slime} - 1}{\text{sp. gravity slime}}$$

In practice, a cubic-foot box and the weight of one cubic foot of water can be counter-balanced, so that the excess, when the box is filled with pulp, can be directly read, and divided at once by x.

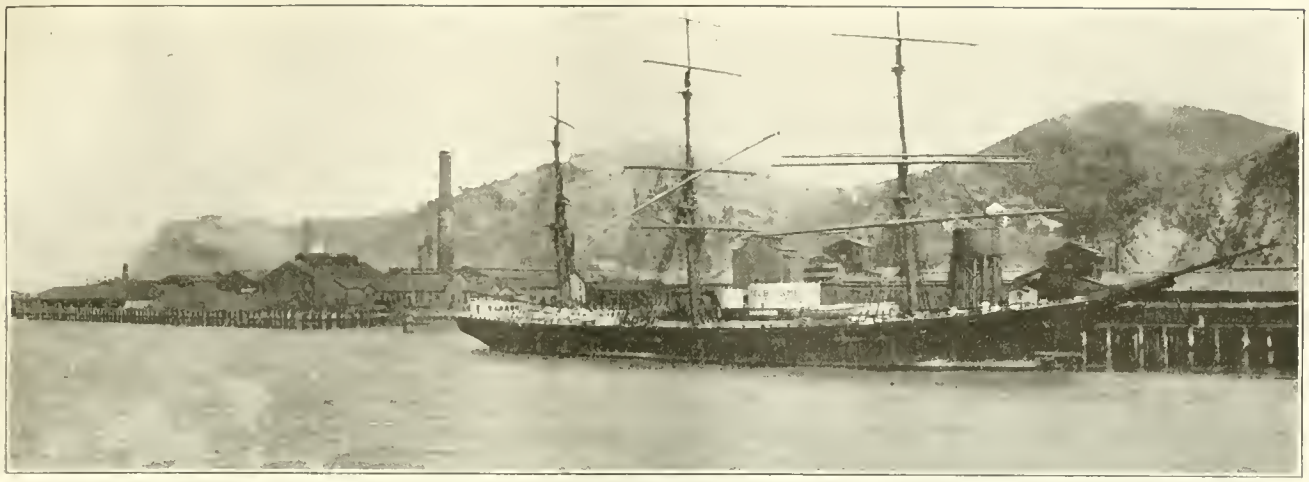
JOHN ALLINGHAM.

Oakland, March 28.

CORRECTION. Asbestos production of Quebec in 1915 was erroneously given on page 474 of this journal of April 1 as $2,895,935. This should be 114,115 tons valued at $3,544,302, an increase of $648,367, but below the total for 1913. Rock mined amounted to 2,134,073 tons, producing asbestos worth $3,118,524, or $1.46 per ton.

IDAHO has an area of 84,800 square miles, which is more than that of Missouri, Washington, Kansas, or South Dakota. Its population of 400,000 exceeds that of Wyoming and Nevada combined. The principal mineral output is lead, the production of which in 1915 was 377,000,000 lb. Shipments of zinc ore and concentrate during 1915 contained zinc valued at over $11,000,000.

EUCALYPTUS OIL. The oil distilled from one of the Australian gum-trees, the *eucalyptus amygdalina*.



THE SELBY SMELTER AND WHARF.

The Selby Lead Smelter

By T. A. Rickard

SAN FRANCISCO is an important mining centre, for it serves as a distributing point for engineers, machinery, and supplies to the Pacific Coast, to the mineral regions of the Great Basin, to the rich South-west and the romantic North-west, from Alaska to Peru, and across the sea to Japan, Korea, and Siberia. As a metallurgical centre, it can boast among its residents several metallurgists of international reputation and on the shores of the Bay at least two noteworthy smelting establishments, the Selby lead works and the Mountain Copper plant. But for an unreasonable prejudice we might have been able to claim a big copper smelter, for the construction of such a reduction plant was actually started in 1906 at South San Francisco. Lack of appreciation for the antiseptic qualities of sulphur dioxide on the part of the untechnical public prevented that useful undertaking from coming to fruition; it was nipped in the bud, so that today our most important smelting establishment is the one that was founded by Thomas H. Selby.

That worthy pioneer came to California from New York in 1850. He established a hardware and iron business that prospered deservedly. In 1864 he built a shot-tower at the corner of First and Howard streets, where it stood as a conspicuous landmark until destroyed in the earthquake-fire of 1906. He imported his lead from England and Spain; but finding this inconvenient and costly, and knowing that there was lead nearer home, he decided to build a small plant to reduce local lead ores and thus supply the requirements of his factory. Thereupon he organized the 'San Francisco & Pacific Lead Pipe & Shot Works.' In 1875 he bought a block of land on Black Point, now the site of the California Fruit Canners Association plant, where he built a couple of smelting-furnaces, to which he added a lead refinery and a plant for parting the gold and silver, as well as a copper sulphate annex, gradually increasing his equipment as the business expanded. In 1876 he died and the enterprise became incorporated under its present name; the Selby Smelting & Lead Company. His son, Prentiss Selby, became general manager, with A. J. Ralston as president and H. B. Underhill, Jr., as secretary. The last is happily still with the company, as its president. At the time when this new start was made the Comstock mines were in bonanza, so that a large part of the bullion from Virginia City was refined at Black Point. In 1879 the Selby company absorbed the Pacific Refinery & Bullion Exchange, previously the San Francisco Assaying & Refining Works, at 416 Montgomery street. The office of the Selby company was transferred to this building and remained there from 1879 to 1907, for it was one of the few down-town structures that escaped the earthquake-fire.

The site at Black Point soon became inadequate for the expanding operations, so that in 1884 the company purchased the present site near Vallejo Junction and 29 miles east of San Francisco, on the strait of Carquinez, which forms part of the estuary of the Sacramento river. This article will describe the plant and its operations as I saw them recently.

Entering the smelter-yard I noticed two bars of fine silver, each of 1100 oz., on a truck. Upon inquiry I was informed that they were going to Joseph Mayer, a manufacturing jeweler at Seattle. Next, Mr. Eugene B. Braden and Mr. E. N. Engelhardt, who were piloting me, stopped to look at a truck full of small pieces of slag. From their remarks I learned that slag of egg size was being sent to the Goldfield Consolidated mill, in Nevada,

to aid in the reduction of gold precipitated from cyanide solution.

In the office Mr. Engelhardt showed me an old photograph, from which it could be inferred how much the plant had been extended. This has been done conveniently, for the dumping of slag has continuously enlarged the site available, so that the smelter now covers an area 1400 ft. by 400 ft. more than it did in 1890. Not only has the slag dump proved useful in this way, but the greater compactness of a modern equipment has tended to restrict the superficial dimensions of the plant as a whole. A number of hand-rabbled roasting-furnaces, for instance, are now replaced by four sintering machines. The blast-furnaces, it is true, have been increased in size, those first built being 30 by 72 inches, as against furnaces of 36 by 144 inches now in use, but even this is small in comparison with those built at Anaconda, which are (or were, for they are being dismantled now to make way for reverberatories) 87 feet long.

Going to the ore-bins, it is evident that one feature of the operations is the large number of small lots, that is, under 5 tons. Any lot less than a carload (15 tons being the minimum on the Southern Pacific and 30 tons on the Santa Fe railroad system) is charged $10 extra, on account of the labor of handling and accounting. Parcels of specimen ore weighing as little as 10 lb. are received. The smallness of some shipments is due to ignorance in regard to the processes involved. Some carloads are too poor to pay the freight, let alone the smelter charges; these are used for grading and are marked 'overboard.'

Among the shipments to be seen on the occasion of my recent visit was the concentrate from the Alaska Gastineau, or Alaska Gold Mines, near Juneau. This first came in the form of two products: (1) a galena concentrate containing 20 oz. gold, about the same amount of silver, and 50% lead, (2) a pyrite concentrate assaying 6 to 10 oz. gold, the same of silver, and 5 to 8% lead. It was found that the iron pyrite, containing over 40% sulphur, exhibited such a tendency to oxidize, even to the point of ignition, as to endanger any ship that brought it. When under its own pressure in the hold it proved particularly dangerous. On one occasion this concentrate actually set fire to a wharf at San Francisco. The pyrite probably is porous and so favors rapid oxidation. This Alaskan concentrate is so agglomerated, by incipient fusion, or spontaneous sintering, that it has to be recrushed before sampling. Now an intimate mixture of the pyritic and the lead concentrates is made, resulting in a product assaying 15 oz. alike in gold and silver with about 25% lead. This mixing increases the difficulty of sampling. Another mine producing easily combustible pyrite is the Green Mountain, near Raymond, in Mariposa county. Shipments of this copper ore burned several box-cars, leading to the use of iron gondola-cars, and compelling the mixing of it with other ore before shipment to Tacoma, for it was forwarded to that copper smelter on Puget Sound.

Among recent shipments may be mentioned silver-lead ore from Mayo, on the McQuesten river, in the Yukon. This assayed 25% lead, 260 oz. silver, and $3 in gold.[2] One of the oldest shippers to Selby is J. J. Gunn, who sends a few sacks of silver-lead ore, hand-picked, from Inyo county. He has been contributing for 25 years.

It is a rule of the Selby sampling department that ore must never touch wood or cement or any material likely to catch the fine stuff and so 'salt' a sample either way, up or down. Three separate rooms are maintained for the final reduction of the samples; high grade, medium, and low-grade. The floors are covered with sheet iron. The shipper or customer is allowed to watch the operations through the iron-screened doors, of which there are so many that good observation is facilitated. These screened doors evoked the remark "safety first" to be taken in either of two ways. All the sampling is done by hand, except the final reduction in small fine-grinding machines. No bucking-board is to be seen. The shipper or his representative can check the moisture determination by drying his own sample, the desiccating being done by steam-heat, so that over-heating is impossible.

Among the lots that I saw undergoing sampling was some chalcopyrite ore from the Island Mountain mine, which is in the south-western corner of Trinity county and is owned by Frank A. Leach, formerly Director of the Mint. The shipment was said to represent the blasting of a big piece, or 'boulder,' of ore detached from the outcrop. Another interesting product was a cream-colored granular material gathered during the dry season by skimming the enriched slime on the settling-ponds of the mills at Tonopah. It assays $20 to $40 per ton.

The superintendent of the sampling department, Charles Richards, has been in the company's employ for 30 years. One of the melters, William Stewart, has 28 years to his credit, and the foreman of the melting-room, William Kitchen, can boast 32 years; while James K. Bulger, now manager of the gold and silver department has a record of 37 years. Indeed, the appearance of the men at work does not suggest unhealthful conditions. I take it that in a smelter, as in life generally, good sense assists a man in preserving his health. As I watched a rubicund operator at the side of a big kettle full of molten lead, I noted that he stood to windward. Care and instinctive observation will enable a worker to avoid injury to his health.

In the room reserved for high-grade material, I saw 25 tons of black silver precipitate (from a cyanide mill) being sampled. At the Mexican mine from which this came it had been deemed safer to ship this product, containing 20,000 oz. silver per ton, in this non-merchantable form rather than risk the danger involved in trying to export silver bullion, which might be seized by bandits, including some one or more of the so-called governments.

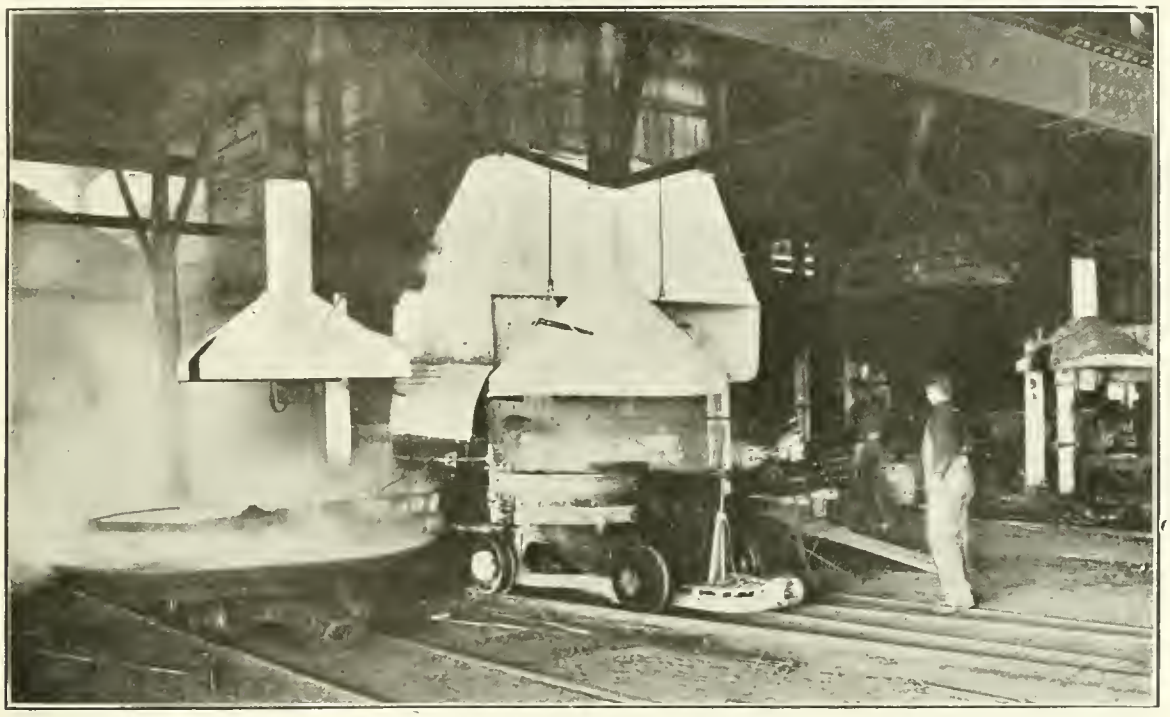
All of the concentrates go to the sintering machines; in their ordinary condition they are too finely-divided for treatment in the blast-furnace. From the various bins the concentrates and fine ores are trammed to an ordinary elevator and thence along an upper floor to steel bins.

[2]See also M. & S. P., July 24, 1915. 'Silver Discovery on the Yukon.' By D. Saunders.

These, called 'feed-tanks,' are cylindrical, with conical bottoms. Eight of them have a capacity of 50 to 60 tons each, and two hold from 80 to 90 tons apiece. The contents of these are fed onto a conveyor-belt, the flow being regulated by a gate set for a specific stream of ore —$\frac{1}{4}$ inch or less. A good mixture is obtained by the mingling of feed from the various 'tanks.' The speed of the belts and sintering machines is regulated by cone-pulleys. The belt delivers into an auxiliary 'feed-tank' with four pockets placed above the four sintering machines, each pocket having a belt running to a corresponding machine. This, the Dwight-Lloyd machine, consists of a continuous series of grates or 'pallets,'

The bag-house is a building in which are suspended a number of cylindrical bags, 32 feet long and 18 inches in diameter, made of woolen cloth, retaining the natural oil of the sheep, so as to serve as a filter through which the fume is forced by a draft. Thus the valuable and deleterious elements of the fume are eliminated and collected. This device was first introduced by Malvern Iles at the Globe smelter, Denver, fully twenty years ago. It has proved not only an economic factor in lead smelting, but it has done much to lessen popular apprehension in regard to the possible injury resulting from smelter smoke.

At the time of my previous visit, in 1908, the fine ore



BLAST-FURNACE, WITH SETTLER, SLAG-POT, AND KILKER MATTE-CAR.

there being 42 of them to each machine, and each consisting of 3 linked grates. The 'pallet' is 42 inches wide and 24 inches lengthwise of the line of movement. The travel of this continuous or linked grate is at the rate of 12 to 20 inches per minute, according to the composition of the charge, giving a capacity of 90 to 150 tons per 24 hours per machine. The fire-box or 'muffle' is made of silica-brick and contains an oil-burner, which points across the path of the ore. The burner consumes 40 gal. of 17° B. oil per 24 hours, with air under 80-lb. pressure. At Tacoma illuminating gas is used for this work; at Denver, coal; and at Monterrey, distillate.[3] To remove the gases a wind-box, under the muffle, is operated by a Sirocco fan making 900 r.p.m. and giving a suction equal to 8 inches of water. This connects with the bag-house, where the fume is condensed, and thence to the stack.

went to four Ropp roasters, of which only one survives. The sintering machines have replaced the roasting-furnaces, plus the fact that the heavy sulphide ore is treated by the General Chemical Company's works near Martinez for the manufacture of sulphuric acid. The one Ropp roaster that remains is operated during four months of the year only, namely, the rainy season, in accordance with an agreement with the farmers of Solano county, who fear injury due to the fume. The Ropp furnace was the invention of Baron Alfred De Ropp, a Russian nobleman, who was in charge of the smelter before it came under the control of the American Smelting & Refining Co., in 1905. He may be said to have been identified with, and responsible for, the most notable expansion of the Selby business. In the roaster that he invented the ore is turned by a traveling mechanical rabble operated by a cable that passes over a sheave at the upper end of the furnace, so that the rabble is outside the furnace half the time, during which it is being cooled. This marks one of the few occasions when a baron got the best of the rabble.

[3]The smelter uses only 15 tons of coal per month, for the little locomotive on the slag-dump and a cook-stove. Oil is used under the boilers and on the forges. Steam is needed in the precipitation plant and to steady the furnace-blast.

When the ore has been roasted and sintered (or agglomerated) it goes to the blast-furnace. No bedding floors are maintained at Selby, the necessary mixing of various components of the charge being effected at the bins, in the manner already described. Each sintering machine discharges into a car, which delivers its load on the upper feed floor of the water-jacketed blast furnace, into which it is shoveled by hand. The water-jacket is made of cast-iron and is fed with salt water from the Bay. The cold water enters at the bottom of the jacket so as to keep the sediment stirred and prevent the jacket from burning. The blast is admitted by 8 tuyeres on each side under a pressure of 35 to 40 oz. per square inch. The ore-column is 14 ft. high. Each furnace smelts from 180 to 200 tons of charge per day, as compared with 130 to 140 tons seven years ago. This increase is due mainly to the fact that the sintering puts the charge in a better physical condition for smelting: it is more porous to the heated blast, and therefore to chemical change. The total weight of a charge is 9250 to 9500 pounds. Of the total about 80% is sintered ore. Limestone, quartz, and metallic iron are added to produce a fusible mixture and a clean slag. Coke,[4] in the proportion of 12 to 13%, equal to 9½% fixed carbon, is required. This comes from Australia and Utah. Slag, up to 25% on the charge, is returned to the furnace in order to regulate the physical condition of the furnace and to correct irregularities in its operation. It is found most practicable to make a slag of the following percentage composition:

SiO_2	26	Al_2O_3	7
FeO	38	ZnO	6
CaO	17		

The undesirable alumina comes in the siliceous ores from Nevada, largely as alunite. The slag also contains 1.5% MgO, from the limestone, and 1 to 1.5% S, besides traces of copper, antimony, phosphorus, etc.—in fact, minute traces of most of the elements.

The limestone used formerly was the reject from the portland cement works at Santa Cruz. Now the Selby company has its own quarry near Martinez. Some limestone is obtained from the Spreckels quarry, the product of which is employed mainly in the refining of sugar.

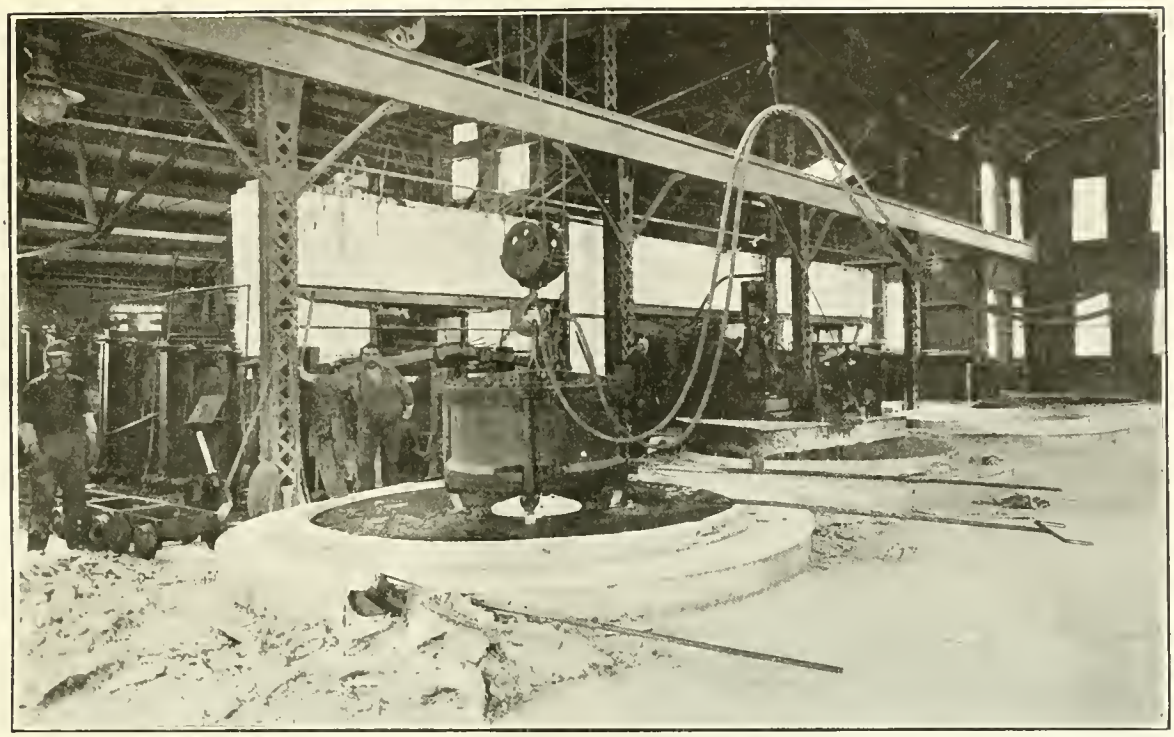
When once in the blast-furnace, the smelting of the charge requires six hours. The separation of the lead from matte and slag takes place within the furnace, the lead being drawn off through an Arents syphon-tap. The matte and slag run out into a rectangular fore-hearth, which is placed on a truck, so that the slag, being lighter, overflows into a settler 6 by 6 ft. and 2½ ft. deep, which, in turn, empties into a slag-car of 23-cu. ft. capacity, holding 2½ tons, drawn along the water-front by a small locomotive, by aid of which it is discharged into the Bay. The matte is tapped at a lower level of the fore-hearth into a revolving Kilter pan or 'merry-go-round.' When cool the matte is broken by sledge-hammers, then passed through crushers and rolls, and sent to the sintering machine to be roasted.

The lead flows from the well of the blast-furnace into moulds and is cast in pigs or bars weighing 90 lb. apiece. It gladdens the heart of a miner to see the lead flowing from the furnace into the mould. The pigs of lead are taken on trucks to the refinery and there elevated to the upper floor, to be delivered into the softening-furnaces (two reverberatories of 70 tons capacity each) in which the processes of softening and liquation are carried out. Liquation, or eliquation, is the process of separating metals by the difference in their melting points. The lead from the blast-furnace in addition to its gold and silver contents, contains copper, antimony, and other metals the presence of which interferes with its industrial utility; hence the necessity for getting rid of them by liquation. The impure lead is melted at a minimum temperature, about 710° F., when the copper comes to the surface in the form of dross, which contains silver and gold also.

The dross is removed by rabbles into a car and goes to a reverberatory for further treatment, whereby the dross is converted into a leady copper matte, which, after being roasted, is returned finally to the blast-furnace. When the copper dross has been removed, the antimony comes to the surface as a scum, which is withdrawn for treatment in another reverberatory furnace, where an antimonial slag is formed. This slag goes to another blast-furnace, where an antimonial lead metal, known as 'hard lead,' is produced. This is sold for making type-metal, babbitt, solder, and other alloys in which antimony forms a useful component. In the near future, instead of casting the lead into pigs at the blast-furnace, it is planned to take the molten metal to the lead refinery, where liquation and its sequel of processes will be conducted in due course.

Copper in any ore is gradually absorbed in the blast-furnace, as metal; it is also skimmed as a dross in the softening furnace and treated in the 'skimming-furnace,' with addition of galena, forming a matte of about 40% copper, which is shipped to Omaha. Returning to the softening furnace: when the charge is 'cooked,' that is, all the copper, antimony, arsenic, etc. have been eliminated, the lead is tapped into desilverizing kettles, 3 ft. deep and 10 ft. diam. There are four of these and they hold 60 to 65 tons each. They are made of cast-iron and are fired by oil, delivered in barges by the Union Oil Co. from the southern oilfields of California. Zinc is added to the lead to collect the silver. The temperature in the desilverizing kettle is raised to the point where a slab of zinc melts readily in the molten lead: this is at 840° F. The zinc unites with, and collects, the silver. It is the old Parkes process. Sufficient zinc is added to desilverize the lead; and as the zinc melts it is mixed, by a mechanical stirrer, into the bath of lead. The scum of zinc that rises to the surface contains the silver, and the gold

[4]Some of the coke recently received is of North German origin; it was delivered through Dutch ports and brought to San Francisco on French sailing vessels that take wheat and barley back with them. The steam-schooners that bring lumber from Puget Sound are glad to take copper ore—unsuitable for Selby, but sold here—to the Tacoma smelter.



DE-SILVERIZING KETTLE, WITH HOWARD PRESS IN A BATH OF METAL.

CUPELLATION FURNACES, WHERE THE LEAD, AS LITHARGE, IS REMOVED FROM THE GOLD AND SILVER.

also, both the precious metals deserting the lead. It is a concentrating process. The lead as delivered into the kettle contains about 150 oz. silver and 7 oz. gold per ton; the zinc scum, after being pressed to remove the free lead, carries 3000 to 3500 oz. doré, this last being the metallurgical term for the two precious metals when mixed in unrefined bar. Literally, doré means golden. Any trace of copper remaining over from the previous treatment is also removed in this zinc scum, which is squeezed in a Howard press so as to extract any uncombined lead. The pressing machine is lowered by a crane into the metal bath and when it has acquired the

temperature of the lead, the scum is ladled into the press. This machine was devised by W. H. Howard, formerly of Pueblo and Garfield, now consulting metallurgist to the A. S. & R. Co. After being pressed the scum from these desilverizing kettles contains 22 to 24% zinc, 10% precious metals, 3% copper, the rest being lead. The scum looks like the native silver, slightly tarnished, to be seen in mines, as in the palmy days of the Mollie Gibson, at Aspen, for example. The molten lead in the kettle resembles mercury, though it is less mirror-like and of lighter lustre. The final scum on the surface of the lead is collected by a wooden rake (which chars, but does not burn) and is lifted out by a flat ladle.

The lead is now free from gold and silver, but still contains some zinc, say 0.5%, and traces of antimony; it is syphoned to a reverberatory furnace on the ground-floor. This syphoning of molten metal is interesting. It is done by means of a 2½-in. iron pipe bent into U shape with one leg longer than the other. The pipe is laid in the bath of lead within the kettle until both are equally hot; then the stop-cock at the lower end is opened and hot lead fills the syphon; the stop-cock is closed; two workmen manipulate the syphon (now full of lead) with tongs and hooked rods so as to get the syphon out of the bath without breaking the column, keeping the end of the short leg within the bath. When the syphon is in place the stop-cock is opened and the lead runs into the furnace below. This has a capacity of 70 tons. Here the lead is subjected to an oxidizing heat whereby all the remaining zinc is driven off by volatilization or is collected as an oxide by the litharge that forms on the surface of the lead; this litharge is skimmed and re-smelted in the blast-furnace.

Finally the lead is tapped into the moulding-kettle, which holds 60 tons, and serves the purpose of maintaining the metal at a suitable temperature while it is being tapped—by a syphon again, but a much smaller one—into 50 moulds, set in a three-quarters circle. Each of these moulds yields a pig weighing 100 pounds of refined lead. When piled in stacks they look handsome.

Now we must return to the treatment of the by-products from the refinery. The zinc dross from the desilverizing process is placed in graphite retorts, where, by distillation, the zinc is driven off in fume that is condensed, as in ordinary spelter practice, yielding metallic zinc and blue powder (zinc oxide), leaving a lead bullion rich in gold and silver. The zinc is first tapped and then the retort is turned over so as to empty the lead bullion into moulds. This doré contains 4000 to 6000 oz. of precious metals per ton. It goes to the cupellation furnace, where the lead is converted into litharge (which goes to the blast-furnace) while the doré bar is sent to the parting plant. Here the silver is separated by being dissolved in strong sulphuric acid, the resulting silver sulphate being precipitated on copper bars, leaving a copper sulphate solution that is precipitated on sheet-lead hanging from wooden bars. This 'bluestone' or crystallized copper sulphate is dried and then sized by screening before shipment in barrels, each holding 400 lb. The small size is bought by the farmers for spraying wheat and the larger lumps go to the electric companies to be used in batteries. Some of the bluestone goes to Mexico to be employed as a chemical in the *patio* process.

Coming back to the parting-room, the liquor from the condensation of the fume escaping from the kettles has a cherry red or ox-blood color due to the presence of selenium, derived from selenides in the Tonopah and Goldfield ores. This gold and silver selenide is converted to a hydrogen selenide that is reduced by the sulphur dioxide generated by the solution of the silver in sulphuric acid. The gold remains in the kettle as a brown residue, like wet crumbs of sponge-cake; this is washed thoroughly, and melted in graphite crucibles, and sent to the mint at San Francisco. A bar of gold 12 by 5 by 3 inches contains 1700 to 1800 ounces. All the silver in solution is precipitated on the copper in 16 hours; the copper plates are lifted, the silver (which looks like soft clay or cement) is removed, by aid of wooden shovels, into a 'sweetening' car, where it is exposed to jets of steam and water for 5 hours, removing all traces of acid. Having been washed, the silver is placed under a hydraulic press; the cakes resulting are put into a melting-furnace, 70,000 to 80,000 oz. at a time, and then cast into bars. Both the silver and the gold are removed to the vault while still hot. There the orderly array of bars brings home the wealth of California, of Nevada, of Idaho, of Alaska. It is good to 'get next' to the realities of mining and to recognize the purpose of the prospecting, digging, stoping, tramming, hoisting, milling, smelting, refining, and other multifarious operations of a basic industry. That purpose is to extract the metals from the rocky crust of the earth profitably.

Mining Costs at the Portland

During 1915 the Portland mine, at Cripple Creek, produced 280,528 tons of ore at the following cost:

	Per ton.		Per ton.
Labor	$0.3269	Assaying and sampling	$0.0271
Explosives	0.1739	Surveying	0.0127
Machine-drill charge	0.1046	Repairs and replacements	0.1525
Supplies, etc.	0.0081	General expense	0.1256
Tramming	0.1753	Office	0.0162
Timbering	0.3022	Development	0.0763
Hoisting	0.1322		
Sorting and loading	0.1374		
Lighting	0.0261	Total	$1.7965

The mine was worked for 338 days, with the following results:

Total shifts	128,266
Average shifts per day	379.5
Average shifts underground	243.5
Total machine-drill shifts	27,710.4
Average machine-drill shifts	82
Average cost per machine-drill shift, besides labor	$1.56
Total cost of explosives per ton broken	0.2141
Tonnage broken per machine-drill shift	13.58
Tonnage handled per shift per man	2.9
Tonnage handled per shift underground per man	4.57

Hookworm Disease Among Miners

By Rush M. Hess

INTRODUCTION. Of tropical and sub-tropical diseases, the least known among miners, though perhaps the most far-reaching in its ill effects, is that of the hookworm. Here is a little parasite, one-third of an inch long, that causes one of the most common, most insidiously harmful, and most easily prevented diseases of man. It is definitely known that the weak mentality, depraved morality, and physical anæmia so common in warm countries are directly attributable to this infection. Especially should we of the mining profession acquaint ourselves thoroughly with its prevention and cure, as the mine with its soft warm mud and commonly careless sanitation, makes an ideal place for pollution and infection. For much of the following information I am indebted to the courtesy of the International Health Commission, which is waging a world-wide battle for hookworm eradication.

HISTORY. The symptoms of the disease were described in records of the Egyptian empire, but its cause was not known. Dr. Angelo Dubini, an Italian, discovered the hookworm in 1888, but its anæmic effect was not suggested. About 1877 both Grassi and Colomiatti discovered the worms in anæmic patients. Since then, this parasite, *ankylostoma duodenale,* has been studied carefully, its responsibility for certain types of anæmia demonstrated, and a successful treatment developed. In 1899 Major Ashford identified the hookworm in Porto Rico and in 1902 Dr. Stiles found the same disease in the Southern States. These worms of the New World, however, are of a different species, *necator americanus,* but look like the Old World type; they produce the same symptoms, substantially the same treatment is effective, and they can all be prevented by the same means.

PREVALENCE. Hookworm disease is more or less prevalent in the entire zone lying from 30° north to 30° south of the Equator, or in practically all tropical and semi-tropical countries, which contain more than half the inhabitants of the globe. In Porto Rico, in low-lying districts of Colombia, or the sugar plantations of Ceylon and Dutch Guiana, infection was found to involve 90% of the entire population. In the United States the disease is found throughout the states south of the Potomac and Ohio rivers, in Arkansas, Missouri, Oklahoma, Texas, and California. Prevalence and severity vary from 1% to more than 90%. In particular is infection severe in the mining districts. At one coal mine in Pineville, Kentucky, in 1911, 65% of the men on the payroll were infected. In 1902 at Liege, Belgium, the official estimate of infection among underground miners was 26%. In 1902 at the Dolcoath mine, in Cornwall, practically every underground worker was infected. In the same year examinations conducted in Rhenish Westphalia placed the infection in certain mines at from 19 to 79%. It is probable that all mines in the rainy parts of the torrid zone are, or have been, infected to even a greater degree.

MORAL AND ECONOMIC EFFECTS. The infected individual has his strength sapped, vitality lowered, and physical and intellectual growth stunted. The social and economic importance of the disease is beyond common comprehension. In the course of a few years a once healthy family has become pale and puny; a once industrious family, languid; and a once prosperous family,

HOOKWORMS CRAWLING THROUGH THE SKIN OF THE HANDS OR FEET, MUCH MAGNIFIED.

in debt. Children lose their mental alertness. Laborers infected accomplish only from 35 to 50% of their normal work. A single California mine employing over 300 men is estimated to have lost 20% of the wages paid, or $20,000 per year, because it had to carry on the pay-roll a large body of men to replace those periodically unable to work because of hookworm anæmia. Beyond question the moral and economic cost of the disease is enormous.

LIFE CYCLE OF THE PARASITE. The life of the hookworm is in two periods. During the first the worms are microscopic and live in the soil (or mine-mud) where they have been hatched from eggs deposited there with the excrement from some infected person. Neither eggs nor larval worms can be seen with the unaided eye. These worms live for ten or twelve months under favorable conditions but cannot develop beyond this point unless they gain entrance into the body of some human being. The larval worms enter the body either by cling-

ing to food which is swallowed, (uncooked food not thoroughly cleansed or which has been contaminated by soiled hands, such as strawberries, plums, celery, and lettuce,) or more commonly by burrowing through the skin of the feet or hands into the tiny blood capillaries, whence they journey to the heart and lungs. The blood-vessels of the lungs being too small for them to pass through, they burrow into the air-spaces of the lungs. They then crawl to the wind-pipe and the throat and are swallowed with saliva and food, reaching the intestine, where they fasten by means of their hooks on its wall and begin their blood-sucking. The second period of the life-history begins with their entrance into the intestinal canal. Here the male and female, after molting twice, develop to adult size. From five to eight weeks are required for their growth, by which time they are from one-third to three-quarters of an inch long and about the size of No. 30 sewing thread. They are usually white, but become dark-brown when full of blood. They may live for years. The female deposits thousands of eggs, which never hatch in the intestines, but pass out with the excreta to spread the disease.

Physical Effects and Symptoms. The adult hookworm, fastened onto the intestine, saps the blood, wounds the intestine, and poisons the body. In severe cases the blood is reduced to one-fourth or one-sixth of normal. In these cases the victim has a sallow complexion, lips pale, eyes listless, pupils dilated, hair dry and scant, face and ankles often swollen, ulcers on legs, and the abdomen is prominent. The chest is often flat and the shoulder-blades stand out prominently. In children there is a marked retardation in development. Appetite is often perverted, even to a craving for clay. Bodies of victims are so weakened that they are unable effectually to fight the more dangerous germs of tuberculosis, typhoid, and pneumonia. Headaches, dizziness, and inability to sleep are common. Light infections, however, may never be suspected, and the existence of the disease can only be confirmed by the finding of eggs in the excreta by microscopic examination. These eggs in their several stages of development are easily distinguishable. Each female hookworm, and there may be more than a thousand of them in a single victim, deposits some twelve to fifteen hundred eggs daily which are passed from the body to pollute the soil and to spread the disease. Infected persons, going from place to place, spread the infection from one community to another. One careless miner may be responsible for the infection of all the men in a mine.

The Thymol Treatment. Hookworm disease is easily cured, and permanently if there is no further infection. From one to seven or even more treatments are given, depending on results. Little or nothing is eaten by the patient at noon on the day of treatment. No dinner that night is allowed. At 8 p.m. a dose of Epsom salts is given. The next morning at 6 o'clock, if the salts have acted, half the thymol prescribed should be given, two hours later the rest of the thymol, and two hours later another dose of Epsom salts should be taken, which will expel the hookworms that have been loosened and poisoned by the thymol. Nothing should be eaten on the day the thymol is taken until the final dose of the Epsom salts has acted well. No alcoholic drinks, oils, butter, or milk should be taken on the day previous to or on the day of treatment. Alcohol and oils dissolve thymol, making it actively poisonous and exceedingly dangerous. The dose of thymol varies with the age of the patient, an adult is usually given 60 grains. Thymol is a poison, and great care must be taken in its use. Deaths have resulted from not following directions.

Prevention. Preventive measures against hookworm are simple. The eggs must not be allowed to develop. Therefore excreta must be disposed of in a sanitary way by burning, fermenting, or burying. Do not use for fertilizer unless thoroughly treated. Pollution of ground and mine must be stopped. Shoes should be worn. Above all, sanitary and fly-proof privies are of prime importance. Educate your men.

Control of Disease. At the Continental Coal Corporation, at Pineville, Kentucky, in 1911, among 1800 men of whom 65% were infected with hookworm, there were about 150 cases of typhoid, and bowel complaints were numerous. After measures were taken to eradicate the hookworm, the same force of men loaded over 33% more coal on the cars, and during the summer of 1912 there was not a single case of typhoid and cases of diarrhœa were reduced one-half. At Liege, Belgium, in 1902, infection among underground miners was 26%. In 1912 the infection had been reduced to 2%. At the Dolcoath mine, Cornwall, in 1902, 94% of the men were infected. Simple prophylactic measures taken, resulting in practically a complete eradication. Infection in the Rhenish-Westphalia district, Germany, has been reduced 95% from 1903 to 1911.

No other disease is perhaps so well understood in every detail and can be so satisfactorily explained. Nor is there any other disease against which the lay community can so surely protect itself by simple precautions. Its conquest resolves itself into a problem of education and sanitation.

Mica production in this country varies irregularly. For instance in 1913, sheet mica to the amount of 1,700,677 lb. worth $353,517 was produced, while in 1914 it was 556,933 lb. worth $277,330. Scrap mica was 5322 tons worth $82,543 in 1913, and 3730 tons worth $51,416 in 1914. Imports in 1913 were 2,239,000 lb. of sheet valued at $943,000, chiefly from India and Canada. North Carolina ranks first in domestic production, much of the output coming from farmers who work at mica-hunting when crops do not require attention; there are small grinding mills for waste. New Hampshire is also important, in which State the General Electric Co. has a plant for trimming mica. Several of the Western States are now producing small quantities of mica. Like many other minor minerals, mica can be handled best by a dealer in such materials who knows the ins-and-outs of the game, has warehouse facilities, and is in touch with the trade. The U. S. Geological Survey pamphlet on the 'Production of Mica in 1914' gives data on prices and production.

The Mine-Mechanic

By P. B. McDonald

A mine-manager recently remarked that he was having difficulty in securing a capable general mechanic who understood mining machinery. He could, he said, get a lot of men who were good mechanics but knew little or nothing about mines, or he could get plenty of men who knew all about mines but were poor mechanics. In fact, he could find a number of men who were almost good enough, but was encountering difficulty in securing just the proper combination in one man. What the manager wanted was a man to take charge of, and be responsible for, all the mechanical and electrical work at the several mines of his company.

The reason why it seems difficult to find a satisfactory man for head of a mine's mechanical department is because mechanics in general have not been attracted to the mining industry. Again, it requires a mechanic of unusual capability to be fitted for master-mechanic for a mining company. A mine-mechanic cannot be purely a mechanic, or he will be attempting to impose useless details on parts of the plants where such refinements are more of a nuisance than an advantage. In addition to ability and training in mechanical lines, he must have adaptability, resourcefulness, and a little of the spirit of mining. Otherwise he will not harmonize in the scheme of the work and will conflict constantly with the other foremen.

Yet by no means should it be assumed that the machinery and plant at a mine are only rough devices requiring indifferent mechanical skill to keep in condition. The machinery used in mining is becoming constantly more elaborate and specialized. The problems arising in the application of steam and electricity to the economical production of ore are more and more necessitating a broad-gauged knowledge of mechanical engineering, whether known under this title or not. Many a man who never attended an engineering college is a first-rate mechanical engineer, and a master-mechanic for a mining company must be a bit of a mechanical engineer just as he must be also a foreman, a miner, and know how to handle electrical apparatus, a 'chain-gang,' or a mining-machinery salesman.

A tendency is becoming evident with the older and better established mining companies to attract graduates of engineering schools into the mechanical department, where they receive a thorough training in the operation of mining machinery. They gradually get to know not only about the maintenance of hoists, pumps, motors, and the miscellaneous array of apparatus common to the business, but they learn the much more difficult feats of installing new machinery, and adjusting it to the special needs of a particular plant, as well as the knack of repairing second-hand apparatus to be used for purposes for which it was not intended. An engineer that has been given a broad training as assistant to the master-mechanic of a large company becomes exactly the man whom some smaller operator wants for taking charge of his mechanical department; and it is usually the case that a man prefers to change from working for a big concern to one where the individual is of more relative consequence.

Some mechanics do not like mining because they prefer not to live in a mining settlement. But other mechanics who have lived among mines for years would not live anywhere else. A mining district may appear like a desolate end-of-the-earth when a man first arrives, but a better acquaintance with its people, coupled with an understanding of mining communities in general, may change the views of the new-comer.

You can usually spot a mechanic at the mine by his greasy clothes and dirty face. Withal, he has a different look from his mining brethren. He is apt to be either more in a hurry than the miners or more at leisure, depending on how the various machines are operating. He may be running for a man-hole gasket or hot-water packing, swearing volubly, or he may be merely sauntering around inspecting pumps, boilers, and hoists. If you are at the mine on Sunday or a holiday, you may see the mechanics looking blacker and greasier than on week-days, 'hard at it' cleaning flues, combustion-chambers, or what not. As a rule, at the mines that do not operate on Sunday, the mechanics have to utilize that day for repairing or installing machinery that is too constantly in operation during the week to permit the work being done then. When things are running smoothly, a mine-mechanic's job looks easy. However, it is a case where looks are not in accord with facts, for at repair-time and when troubles arise, such a job is no sinecure.

Minerals of Bolivia

Exports of the principal minerals during 1915 were as follows, in kilograms of 2.2 pounds:

	1915	1914	1913
Antimony	13,085,044	186,077	62,050
Bismuth	568,610	437,751	390,537
Copper	17,872,054	3,874,272	4,019,635
Silver	77,810	72,336	81,289
Tin	39,312,182	37,259,617	44,594,088
Wolfram	499,604	276,316	282,577

These products are generally exported in the form of concentrate.

The total value was about 77,000,000 *bolivianos*, or $30,800,000. The total value of all commodities exported in 1915 was Bs. 84,878,384, showing the importance of the mineral industry. The rubber industry was also prosperous.—*El Diario* of La Paz.

Gold production of West Africa in 1915 was 412,273 oz., against 419,510 oz. in 1914 and 397,679 oz. in 1913. Some December returns were as follows:

Mine.	Tons.	Value.
Abbontiakoon	11,707	$130,000
Abosso	9,732	72,000
Ashanti	10,778	195,000
Cinnamon Bippo	4,167	34,000
Prestea Block A	23,500	178,000
Taquah	5,720	82,000

Precipitating Action of Carbonaceous Shale in Cyanide Solution

By Paul W. Avery

THE paper* by W. R. Feldtmann on the precipitating action of carbon in cyanide solutions has been of great value to me in explaining many points in connection with the cyanidation of our San Carlos vein here at Esperanza.

When we began the treatment of ore from this vein we noted that extraction reached a maximum in about eight or ten hours. After agitation had been carried beyond this point, say, to 24 hours, the gold content began to rise and sometimes was almost double that obtained in the first eight hours of treatment. Further agitation with stronger cyanide solution caused no appreciable drop in the gold content; the silver, however, continued to decrease. We also have had lot-samples the residue from which would drop steadily to about 50% of the head and there remain with no change either way. The following will show this precipitating action or 'kick-back,' as we call it around the plant:

SAMPLE IC

Time hours	Gold grams	Silver grams	Time hours	Gold grams	Silver grams
—	7.11	33.55	18	2.66	16.89
2	1.22	18.89	20	2.22	15.55

12	1.44	15.33	36	2.55	13.89
14	1.44	16.00	40	2.55	14.33
16	1.88	17.45	44	2.66	16.00

SAMPLE IB

Time hours	Gold grams	Silver grams	Time hours	Gold grams	Silver grams
—	6.66	35.22	14	4.00	19.55
2	3.55	25.22	16	4.11	20.22
4	3.66	24.25	18	3.78	19.77
6	3.33	21.55	20	3.66	18.67
8	3.33	20.89	22	3.66	17.84
10	3.44	20.78	24	3.66	18.50
12	3.88	20.45			

This ore carries about 50% of a black carbonaceous shale; when crushed in solution and flowing through the launders a thin film of graphite may be seen floating on the surface very much like oil. This film of carbonaceous matter must have great precipitating power, as it assays high, principally in gold. Samples of shale from this vein were found to possess variable precipitative efficiencies, which fact possibly explains why we obtained excellent results on certain batches of ore by ordinary cyanidation and poor results on others. The following series of tests on a number of shales will show this:

*M. & S. P., May 22, 1915.

	Gold gm.	Silver gm.
Original shale	0.16	30.84
After 2 hours' contact with pregnant solution	13.22	64.34
Pregnant solution	3.80	18.37
Solution after contact	0.09	6.57

Conditions: 250 grams of shale ground through 100-mesh and then brought in contact with 1000 cc. pregnant solution.

	Gold gm.	Silver gm.
Original shale	0.16	6.84
Pregnant solution	7.16	49.22
Solution after 96 hr. contact	4.67	46.10
Loss	2.49	3.12

Conditions: 100 grams of shale brought in contact with 500 cc. solution.

	Gold gm.	Silver gm.
Original shale	0.50	3.00
After 18 hr. contact with pregnant solution	9.62	18.80
Separated into sand and slime by panning.		
Sand 47.4%	7.41	20.42
Slime 51.6%	11.83	25.50
Separated by screening through 200-mesh		
Oversize 15.9%	10.17	9.58
Undersize 84.1%	10.66	23.34
Original shale	1.00	6.67
After 18 hr. contact	2.83	14.17
On-going pregnant solution	4.08	16.55
Solution after contact	3.80	18.10

Conditions: 100 grams of shale brought in contact with 500 pregnant solution.

	Gold gm.	Silver gm.
Original shale	1.00	11.00
After 18 hr. contact	7.33	22.67
On-going pregnant solution	5.76	25.48
Effluent solution after contact	3.16	24.24

Conditions: 200 grams brought in contact with 1000 cc. pregnant solution.

	Gold gm.	Silver gm.
Original shale	1.22	18.45
After 18 hr. contact	2.00	10.67
On-going pregnant solution	22.64	71.96
Effluent solution after contact	22.40	73.72

Conditions: 200 grams of shale brought in contact with 800 cc. pregnant solution. In this case the shale has little precipitating power for gold and none for silver.

Experiments to dissolve by cyanide the metal adsorbed by the shale were not successful, in some of the tests bromo-cyanide was used with little or no benefit. We made a great number of tests to find out some way of neutralizing, as far as possible, the 'pre-precipitating' power of this carbonaceous material.

Our tests on sorted samples, after the shale had been separated by hand from the quartzose-calcitic portion,

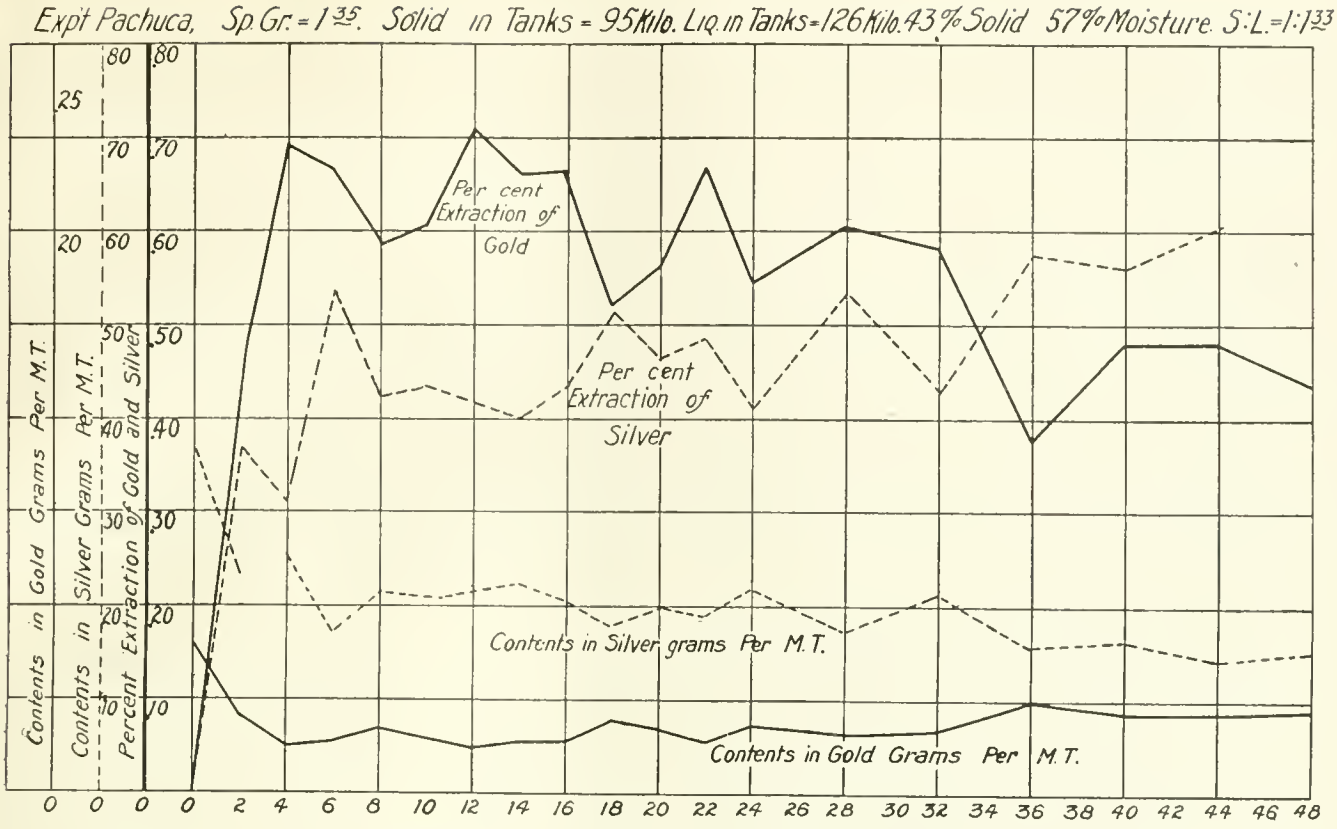

FIG. 1. CYANIDATION OF SAN CARLOS ORE WITHOUT PRELIMINARY TREATMENT.

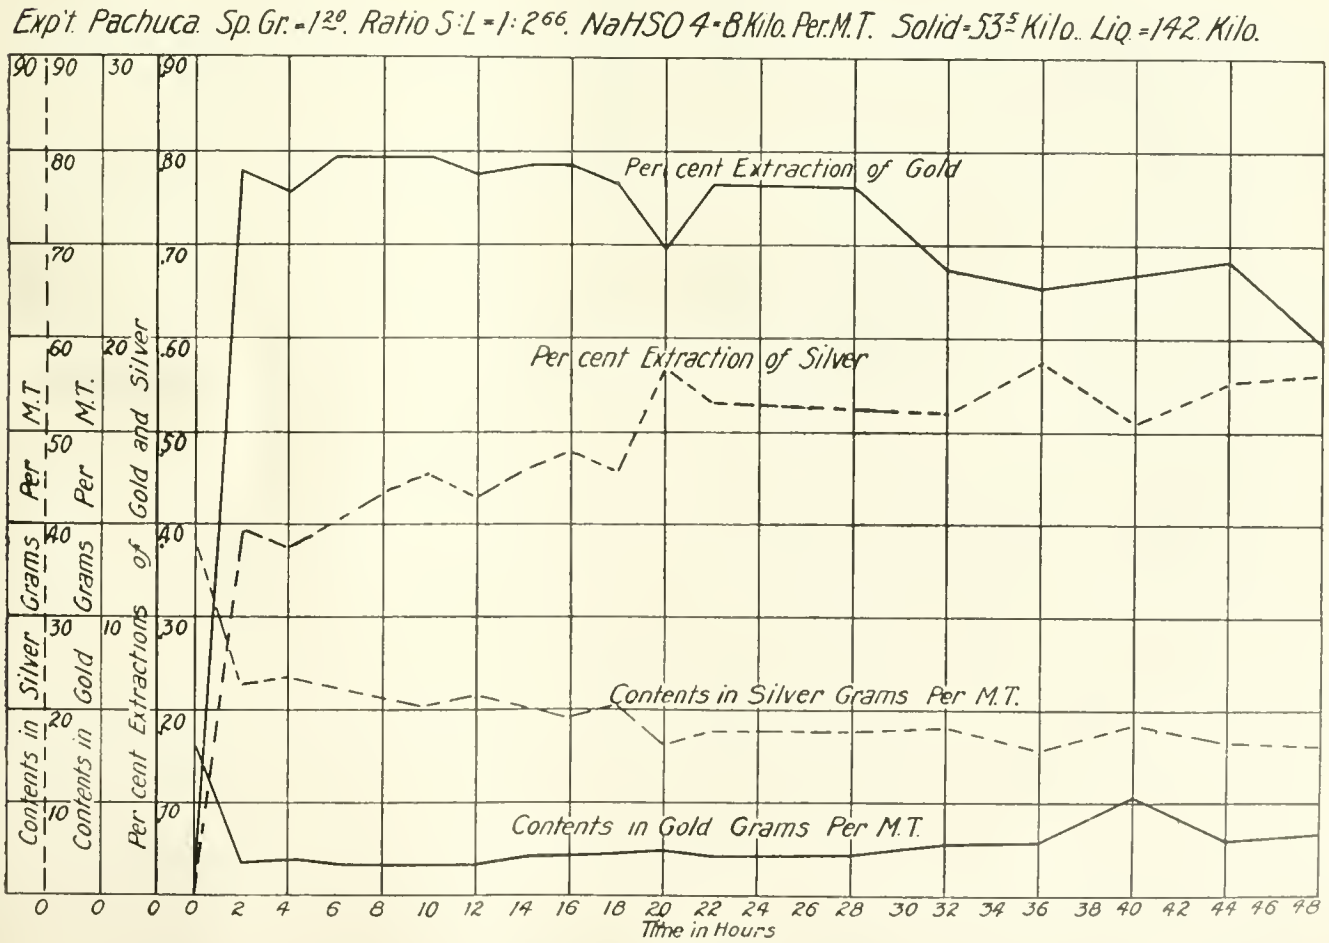

FIG. 2. SAME WITH PRELIMINARY OXIDATION.

showed that the latter had no precipitative power whatever. The shale itself carried but little gold or silver, and if it were possible to hand-pick or otherwise separate the two, our problem would be solved. Separation was tried in drag classifiers, on Wilfley tables, etc., but was found of no avail.

Mechanical separation being impossible, the problem resolved itself into a chemical one, which meant the neutralization of the precipitating power of the shale in the ore by a preliminary treatment in a circuit of its own. This necessitated crushing in water absolutely free from cyanide, with some cheap chemical. We conceived the idea of violent air-agitation in the presence of commercial caustic soda.

Years ago when working on the 'blue ores' of the Black Hills, South Dakota, E. C. Knowles and I tried strong caustic liquors in the presence of air under pressure to break up the refractory sulphides that carried the precious metals in combination. So far as our small laboratory-tests went, the idea was a success, so much so that we took out patents in the United States and Mexico. We described the process as one of oxidation, for without some oxidizing agent no effect was noticeable. After a contact of about 12 hours the 'blue ore' sample, which was a dark-slate color originally, changed to a light-yellow, and upon cyanidation yielded its gold contents readily. We considered that the process amounted to a 'wet roast.' I cite the above to show what prompted us to try caustic soda as an oxidizer in the case of neutralizing carbonaceous shale. After preliminary treatment on the San Carlos ore with caustic liquors as strong as 2%, no difference in color was noted as described in the case of the oxidation of the 'blue ores.' The effect was marked, however, in lessening the precipitating action of the shale.

If strong caustic liquors are required, it will be necessary to filter off and give the pulp a light wash with water before re-pulping in cyanide solution. The reasons for this are obvious, as caustic soda in excess causes poor slime settlement, bad precipitation with zinc, and interferes with the extraction of the gold.

With these objections in view we tried another chemical, namely, commercial sulphuric acid, with encouraging results, but with this decided advantage that there were no ill effects such as noted with caustic soda, no matter how large an excess was added. We have since tried an acid salt—commercial bisulphate of soda—which answers quite as well and is much cheaper.

There is one important point to which I wish to call attention, after studying a number of tests made both with caustic soda and with acid. When the time of maximum extraction has been determined, the treatment should be regulated accordingly and the shaley pulp passed through the filters and out of the plant as quickly as possible. The treatment as outlined above only tends to allay the precipitative power for a time, and if the agitation in cyanide is prolonged unnecessarily this precipitative power may slowly return.

To carry out this preliminary oxidation treatment prior to cyanidation, the finely ground pulp should be given violent air-agitation in a Pachuca tank with a short column-pipe or without one altogether; the water should not carry a trace of cyanide. If a strong caustic soda solution is used, say, 2%, the liquor will have to be used in a circuit of its own and the pulp filtered, getting at the same time a light water-wash. The pulp then should be ready for cyanide treatment. If low strengths only of caustic soda be required, this step would be unnecessary as regards cost of chemical and interference in subsequent cyanidation. If a commercial acid or commercial acid salt is found effective their use would be more advisable than an alkali, as the constituents of the ore often neutralize any free acidity and cause no deleterious effects in the cyanidation. The large proportion of calcite in the shale here effects this.

Reference to the accompanying curves, one with preliminary treatment and the other without, will show many of the points mentioned. The following series indicates the effect of $NaHSO_4$ in allaying the precipitative tendencies of the shale:

SAMPLE IA

Time hours	Gold grams	Silver grams	Time hours	Gold grams	Silver grams
—	10.16	40.17	14	1.33	18.78
2	1.44	21.89	16	1.33	17.78
4	1.33	20.45	18	1.44	15.89
6	1.33	17.67	20	1.67	15.54
8	1.44	....	22	1.67	15.33
10	1.55	18.23	24	1.67	15.66
12	1.22	18.89			

In the above test the pulp (85% *minus* 200) was given a preliminary aeration in water with equivalent of 8 kilo. $NaHSO_4$ per metric ton of ore.

At present I am not prepared to state what effect alkaline sulphide solutions will have in dissolving gold precipitated on our carbonaceous shale. Experiments will be undertaken in the near future to determine this point. Perhaps a combination of the two methods, that is, preliminary oxidation with chemicals in water and post-treatment of the cyanide residues with sulphide solutions, may bring better results than either used singly.

While a few of the satisfactory results obtained by preliminary oxidation were those of large tests (about 75 tons), the greater part were from small lots (from 1 kilo. to 100) and will only be proved or disproved after a continued run on a milling scale of the same ore that formerly gave unsatisfactory results by ordinary cyanidation.

The concentration of this ore by flotation has given some most interesting and satisfactory results, which I shall present at some future date.

THE TWO GREATEST METAL-PRODUCING STATES west of the Mississippi river in 1915 were Arizona and Montana. The output of each was nearly $90,000,000 in copper, zinc, gold, silver, and lead, as compared to $60,000,000 for Arizona in 1914 and less than $50,000,000 for Montana. This output of minerals is exceeded by States east of the Mississippi that produce large quantities of coal and iron ore, and by California's figure of $95,000,000 including oil to the value of $40,000,000.

Machinery for Cyaniding Flotation Concentrate

By A. E. Drucker

INTRODUCTION. Since flotation is likely to play a prominent part in the treatment of gold and silver ores, the cyaniding of concentrate on the spot will be of increasing importance. I do not think that flotation will be a cure-all. It will be applied mainly to the treatment of the slime of sulphide ore. Heretofore the methods of concentrating slime on tables, vanners, and buddles have not been efficient. The slimed sulphide escaping in many cases largely accounts for the comparatively low recovery by concentration. Flotation should be the remedy, while tables will continue to treat the coarser products of sand free from slime.

TREATMENT. As far as the cyanide process is concerned, two distinct concentrated products would be obtained with a plant employing sand-tables and slime-flotation cells: table-concentrate, containing coarse sulphide mineral, would require fine grinding with cyanide solution in a tube-mill direct; flotation-concentrate, consisting of very fine mineral, would in the majority of cases not require further grinding prior to cyanidation.

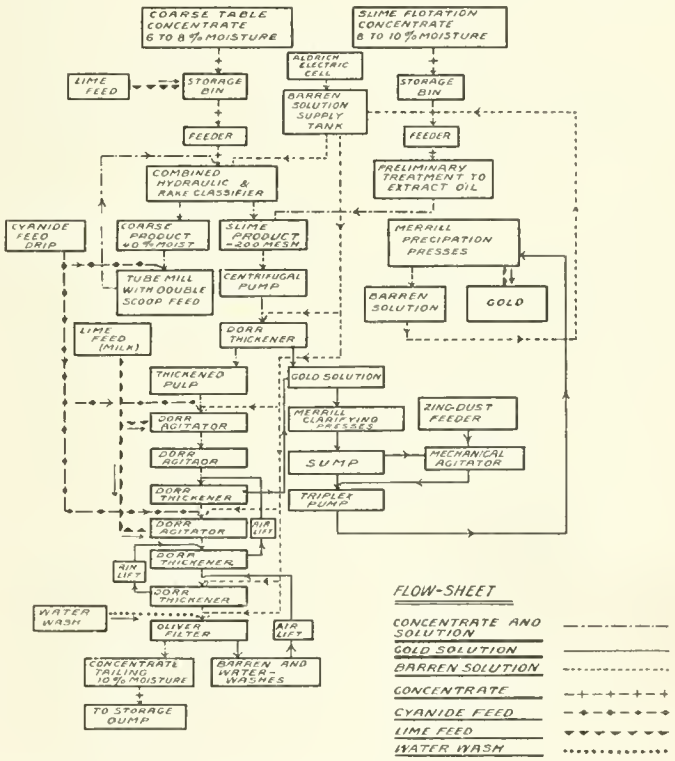
Charles Butters has already pointed out* the difficulty of cyaniding flotation-concentrate where an insoluble oil has been employed. Sulphide particles coated with a thin film of insoluble oil would certainly prevent cyanide solution from coming into contact with the gold and silver. In order successfully to cyanide such a product, some soluble oil that can be readily dissolved by a preliminary treatment is necessary. Oil allowed continuously to enter a solution would soon cause it to become foul and rotten. This should be avoided.

In order to obtain over 90% of the gold value from a sulphide that is amenable to cyanide treatment in a reasonable time (48 hours), it is necessary to grind to 200-mesh. In some cases it would be necessary to pass 300-mesh, while in some exceptional cases (gold telluride and silver ores) where the metals are chemically combined with the sulphide, the finest grinding would not suffice. A preliminary roast would be required.

Concentrate taken directly from tables and not allowed to oxidize can be passed to the tube-mill and ground in cyanide solution without any previous alkaline or water washes. I recommend all *minus* 200-mesh products to receive a thorough air-agitation in solution followed by counter-current decantation, and vacuum-filtration. Zinc-dust precipitation in Merrill presses of the resulting gold solution, I have found most satisfactory. The presence of small amounts of copper in the solution does not interfere. Strong cyanide solution (0.2 to 0.3%) with a high protective alkalinity gives the best result. I have found the Aldrich electric cell installed in the barren-solution feed-tank to tube-mill a benefit. Various reducing agents in solution are kept at a minimum.

The general method of treatment which I suggest for the average concentrate is given in the accompanying flow-sheet.

I shall now discuss the most suitable cyanide machinery, and the most improved and simple plant to treat an average concentrate. My decision is based on



some years of experience in the U. S. A., Mexico, Korea, and Colombia, as well as from the examination of plants in Australia, New Zealand, and South Africa.

GRINDING MACHINERY. For fine-grinding concentrate there are available tube-mills, conical mills, and pans.

Conical mills and pans are good intermediate grinders up to 100-mesh, and to this point they are economical.

The tube-mill in sizes of 3 by 12 ft., 4 by 16 ft., and 5 by 20 ft. would be the more economical and efficient machine for all-sliming (−200), such as is required for concentrate. It is the best all-sliming mill on the market.

CLASSIFIERS. For classifying concentrate prior to fine grinding we have: Callow or Caldecott diaphragm-cones, hydraulic classifiers, Dorr or Akins mechanical classifiers, and the combined hydraulic and rake classifier.

*M. & S. P., November 29, 1915.

Diaphragm-cones and hydraulic classifiers require too much attention in order to produce at all times a uniform feed to the tube-mill. They return too much fine material and are a continual source of trouble.

Dorr and Akins classifiers require little attention and will deliver a uniform feed with 20 to 30% moisture. The chief objection to these machines, when dealing with a heavy sulphide concentrate, is the delivery to the tube-mill of a considerable amount of fine material that does not require finer grinding.

The combined hydraulic and rake classifier in closed circuit with a tube-mill will produce a feed of 30 to 35% moisture. It is easily adjusted to any product and is the most suitable machine for treating concentrate.

Pumps and Elevators. For conveying concentrate containing from 6 to 10% moisture, belt and push conveyors are used, while for elevating purposes belt-bucket elevators are common. Elevators are a source of trouble, and if possible should be avoided.

A variety of different pumps is on the market for elevating pulp, but those that are really good are few. Machines used for this purpose are the Frenier spiral, centrifugal, three-throw plunger, air-lift, bucket-elevator, and tailing-wheel.

The Frenier is satisfactory for low lifts up to 8 to 10 feet.

A three-throw plunger pump will give trouble with sandy material. The valves cut out quickly and the packing requires renewing often. Air-lifts are simple, but require large quantities of air for ordinary lifts of 8 to 10 feet.

The old tailing-wheel gives the least trouble of all. It is reliable and the cost of repairs is low. The one objection against it is the high first cost to install.

For moving sand a well-designed centrifugal pump with white cast-iron liners, easily accessible for replacing worn-out parts, will give good satisfaction; the Byron-Jackson pump is an example.

Agitators. For the agitation of heavy sulphides we have a choice of the old mechanical agitator with plow-shoes revolving at 16 to 18 r.p.m., the Pachuca, or the Dorr machine.

The old mechanical agitator requires too much power to operate.

The Pachuca or Brown agitator is an efficient machine for concentrate, but in the majority of cases the cost of pumping the pulp into these tall tanks is the one serious thing against them. It has also the disadvantage of being costly to erect.

A Dorr agitator, in my opinion, is cheapest in first cost, requires less power, and will operate with the least amount of trouble. It is my choice for a concentrate ground to pass a 200-mesh screen.

The Trent or Hendryx machines are not suitable for heavy sulphide material.

Thickeners. Apparatus available for thickening pulp prior to agitating and filter-pressing are the old sets of pointed boxes, Callow cones, and Dorr thickeners.

Callow cones or pointed boxes have a low capacity, and many would be required to do the work of one Dorr thickener of 30-ft. diam. Consequently many separate spigot-discharges would require constant attention in order to obtain a clear overflow and thick underflow.

The Dorr thickener is, I think, the best. It requires only 1 hp., and operates continuously without trouble. The cost for repairs is practically nothing.

Filter-Presses. For the treatment of heavy sulphide we have the Oliver vacuum-filter, the Kelly, and Dehne pressure-filters.

Dehne presses are used extensively for concentrate in Western Australia and at Waihi, New Zealand. Three-inch cakes are formed at 40 lb. pressure and are washed satisfactorily.

The Kelly press is used at the Goldfield Consolidated and the Alaska Treadwell with satisfactory results.

The Oliver filter is now used more than any other for filtering and dewatering concentrate (8 to 10% moisture) in connection with the cyanide and flotation processes. The thin uniform cake ($\frac{1}{4}$ to $\frac{1}{2}$ inch) certainly permits of a more perfect wash than does the 3-in. cakes in a Dehne press. It is the most suitable filter for concentrate.

Clarifiers. For clarifying solution prior to precipitation, we have the sand-filter tank or the Merrill clarifying press.

Sand-filters are in common use. An extra tank is always required in reserve; a plant of ample capacity occupies a large floor-space and is expensive to erect.

The Merrill press occupies a small floor-space, has a large capacity, and is readily cleaned without opening the frames.

Precipitation. We have our choice between the ordinary extractor-box, using zinc-shaving, or the Merrill precipitation press, using zinc-dust.

Zinc-boxes are efficient, but occupy considerable floor-space, and are not simple when it comes to the clean-up. There is always the aggravating problem of the 'zinc shorts.'

Merrill presses are compact, thief and fire proof, and allow a quick clean-up. In precipitating strong (0.2 to 0.3% KCN) and rich solution with concentrate treatment, they give good satisfaction.

Solution-Pumps. Centrifugal, three-throw plunger, and air-lift pumps are in common use for elevating solutions.

Centrifugals are probably used more than any other for elevating to heights of 10 and up to 50 ft. They require considerable attention owing to their high speed.

A three-throw plunger will pump solution to a height of 100 ft. or more. They require little attention, and are economical in every way. I prefer them to centrifugal pumps.

The air-lift is suitable for lifts not exceeding 10 ft., and is particularly useful about a plant using the counter-current decantation process where the lift would not exceed 2 to $3\frac{1}{2}$ feet.

Plant. For concentrate, I recommend a plant consisting of a tube-mill with combined hydraulic and rake

classifier in closed circuit, Byron-Jackson sand-pumps, Dorr agitators and thickeners for continuous counter-current decantation, Oliver filters, Merrill precipitation and clarifying presses, and triplex plunger-pumps for solution.

If possible, the plant should be erected on a side-hill, allowing ample fall throughout. It is well to figure on sufficient dumping-ground below the plant in order to store tailing for a possible future re-treatment.

Every effort should be made toward simplicity of design, and to have as near as possible an all-gravity arrangement. By so doing, the use of troublesome bucket-elevators and pumps can be avoided largely. What does it matter if one is obliged to elevate solutions 60 or 70 ft. from sump to supply tank in order to obtain the desired gravity arrangement?

Costs and Extractions A modern concentrate-plant such as the one recommended in this article would cost from $800 to $1200 per ton of capacity per 24 hours, depending upon the cost for transport, labor, and material.

Treatment costs per ton of concentrate will vary between $2.50 and $5, depending upon tonnage, cost of supplies delivered at plant, and labor.

The extraction of gold with the all-sliming process would vary between 90 and 97% on a raw concentrate that is amenable to cyaniding. The Oriental Consolidated, Alaska Treadwell, Esperanza, Waihi, and others are examples.

Simple Test for Nickel

The following directions for a test for nickel have been prepared by W. C. Wheeler, of the U. S. Geological Survey:

Grind to a fine powder a sample—2 or 3 grams (30 to 40 grains); treat in a test-tube with a few cubic centimetres of *aqua regia* (a mixture of 1 part nitric acid and 3 or 4 parts of hydrochloric acid), and boil nearly to dryness; then add enough nitric acid and water to dissolve all soluble substances. Filter if necessary. Dilute to 10-15 cc. (about one-third the contents of a test-tube 6 in. long and ¾-in. diam.), add a gram or more (half a teaspoonful) of citric acid (solid), and dissolve by heating. Make the solution slightly ammoniacal, noting that it should contain no precipitate. To the slightly ammoniacal solution add about 2 cc. (a half teaspoonful) of 1% alcoholic solution of dimethyl-gloyxime. A voluminous scarlet precipitate indicates nickel. The *aqua regia* solution is boiled nearly to dryness to remove from it the large excess of acid and anything, such as hydrogen sulphide, that would cause the precipitation of iron, cobalt, nickel, etc., in the ammoniacal solution. The citric acid will prevent the precipitation of iron and aluminum as hydroxides, but will not prevent the precipitation of sulphides of iron, cobalt, nickel, and some other metals in the ammoniacal solution. If a brown precipitate of iron forms after the solution is made ammoniacal, it contains an insufficient quantity of citric acid.

Notes on Molybdenum

In identifying minerals a knowledge of their characteristics may be as valuable as chemical tests. A short description of molybdenum minerals is given by Frank L. Hess of the U. S. Geological Survey, in 'Mineral Resources.'

Three molybdenum minerals are fairly common—molybdenite, wulfenite, and molybdenum ochre. Molybdenite, molybdenum sulphide, MoS_2, containing 60% molybdenum, occurs in thin, bright, lead-colored flakes, which bend readily but are not elastic and are easily scratched by the finger nail. The flakes may be so minute that they coat a surface like paint, or they may be several inches across, and they may be regularly bounded by straight lines and piled up into doubly terminated hexagonal crystals. The mineral, however, is more likely to be found in irregular lumps, easily cleavable into thin leaves. Its specific gravity is about 4.5.

Molybdenite is associated with many kinds of rocks and veins, but occurs most plentifully in association with granitic rocks, especially with granite pegmatites. The deposits are invariably pockety.

Wulfenite, lead molybdate, $PbMoO_4$, contains 39.3% MoO_3. It usually occurs as lustrous resinous yellow, orange, or red tetragonal crystals in the oxidized parts of lead deposits. It may be greenish or brownish, grayish, whitish, or colorless. The crystals are generally platy, but may be nearly cubes or double pyramids. The mineral is very brittle. It has a hardness of 2.75 to 3 and a specific gravity of 6.7 to 7.

Molybdenum ochre, hydrous ferric molybdate, $Fe_2O_3.3MoO_3.7\frac{1}{2}H_2O$, generally forms a bright yellow powdery mineral, though it also appears in small radial crystals. It is a weathering product of molybdenite, but is probably never found in sufficient quantity to be of commercial value.

Powellite, calcium molybdate, $CaMoO_4$, is a white or grayish mineral formed by the weathering of molybdenite. In some specimens tungsten replaces a part of the molybdenum. Like molybdenum ochre, it is not found in deposits of sufficient size to be of commercial value.

Any of these minerals, except molybdenite, may be tested by heating a small piece in a porcelain crucible (a particle half the size of a grain of wheat is enough) with a drop of sulphuric acid until the fumes have nearly ceased. When the crucible has cooled, it will have a beautiful deep blue coating.

Molybdenite must be oxidized before it can be tested in this manner. It may be oxidized either by boiling it to dryness with two or three drops of nitric acid or by powdering and roasting it in the air for a few minutes. The sulphuric acid is then added and the test performed as indicated.

When molybdenite contains no mica, or other substances harmful to steel and difficult to separate, it is most valuable.

Prospecting for Phosphate Rock

*In prospecting for phosphate rock in the Rocky Mountains, the search should be confined to rocks, generally limestone, near the top of the Carboniferous system. In the central portion of this area the formations in which phosphate is most likely to be found are easily recognized.

One of the chief difficulties that presents itself in prospecting for phosphate in the Rocky Mountain region of Canada is that of recognizing the rock when it is found. It bears a close resemblance in appearance to the limestones and magnesian limestones, as well as to certain of the cherts found abundantly in Upper Carboniferous strata. The prospector should provide himself with acid and employ it freely. An excellent receptacle for this purpose is one of the larger bottles in which ink for safety-pens is sold. These are provided with a rubber cork, pierced by a glass tube drawn out to a narrow opening at one end with a collapsible rubber bag at the other. The whole is enclosed in a light wooden case with a screw top. The bottle should be filled with hydrochloric acid diluted with an equal volume of water.

In examining any specimen of dark rock a few drops of acid should be dropped on it. If effervescence results, the rock is limestone. If not, the specimen should be pounded with the hammer to bruise it, and the powder so produced should be treated with the acid. If it now effervesces, it is a magnesian limestone. If it still shows no effervescence, scratch it with a hammer or knife. If a narrow line having a bright metallic appearance is traced on the surface of the rock, it is harder than the steel and is a chert or fine-grained quartzite.

If the specimen belongs to none of these, it should be examined with a lens, when, if phosphate rock, it will probably show a surface studded with minute black spheres or circles. This is the oolitic structure. The rock, if massive, will be distinctly heavier also than common rocks. Sometimes upon breaking it a fetid odor can be noticed. In order to be certain that the specimen contains phosphoric acid, it is necessary to make a chemical test as follows:

Powder some chips of the rock in a mortar until the material will pass a 100-mesh sieve. Place as much of the powder as can be taken up readily on a 25-cent piece in an ordinary small enameled cup, add 30 cc. water and 10 cc. concentrated nitric acid. Filter, or decant the fluid if it is clear, into a glass beaker, and add 100 cc. water, then a little saturated solution of ammonium carbonate. This will probably make the clear solution somewhat cloudy. Nitric acid should then be added drop by drop until the solution clears again, and gives a faint but distinct acid reaction with blue litmus paper. The solution is then warmed to a temperature of 70 or 80° C., and 50 cc. of a concentrated solution of ammonium molybdate is added, drop by drop, while the solution is being stirred. This solution is allowed to stand in a warm place for 15 minutes; if phosphoric acid is present, a bright yellow granular precipitate of phosphomolybdate of ammonia will appear.

If it is desired to determine approximately in the field the proportion of phosphoric acid, the following method, essentially that used by the U. S. Bureau of Soils in the examination of the phosphate beds of the West, may be employed:

The sample is crushed in an iron mortar, pulverized in a small porcelain mortar, and finally put through a 100-mesh screen. Two grams of the powder is weighed and brushed into an enamel cup; 25 to 30 cc. water is added, and then 10 cc. concentrated nitric acid. The cup is covered with a watch-glass, placed on an iron plate over a coal-oil burner, and the contents allowed to digest for seven or eight minutes. After cooling somewhat, the insoluble material is filtered, washed thoroughly on the filter, and the filtrate made up to 200 cc. with water. This solution is thoroughly mixed, and 20 cc. of it is taken for analysis. This is diluted with 30 cc. water and a little saturated solution of ammonium carbonate is added; then sufficient nitric acid to dissolve any precipitate and render the solution acid. The beaker is placed on the hot plate, heated to 70 or 80°C., and 100 cc. concentrated solution of ammonium molybdate is added, drop by drop, with constant stirring. After standing 10 minutes, the solution above the precipitate of ammonium phospho-molybdate is decanted and filtered, and the precipitate washed until the washings give no acid reaction. The filter and its contents are then returned to the beaker, a little water added, and then a standard solution of potassium hydroxide from a burette until the yellow precipitate dissolves. A few drops of phenol-phthalein are added and standard nitric acid (matched against the potash solution) is run in from a burette, drop by drop, until the pink color of the indicator—phenol-phthalein—disappears. The quantity of nitric acid used, subtracted from the amount of potassium hydroxide, gives the number of cubic centimetres of the latter solution required to dissolve the yellow precipitate. The potassium hydroxide employed should be of such strength that 1 cc. equals one milligram of phosphoric acid.

In order to be certain that all the phosphoric acid has been precipitated, it is well to add another 25 cc. of the ammonium molybdate solution to the clear filtrate from the yellow precipitate, and allow the beaker to stand on the warm plate for another half-hour. The standard solution of potassium hydroxide, as well as the standard nitric acid, should be carefully prepared in a laboratory, and taken into the field in stout-stoppered glass bottles.

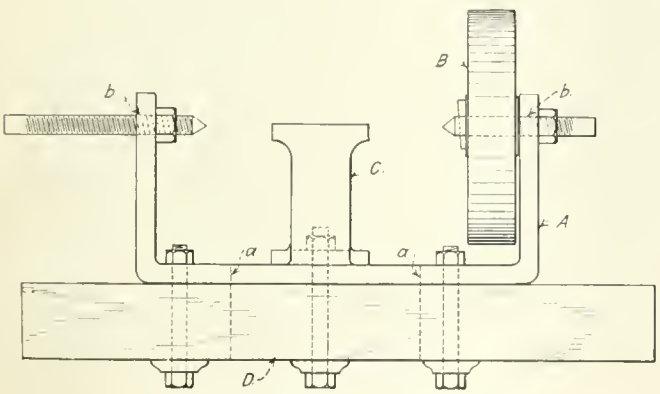
*Abstract from 'Discovery of Phosphate of Lime in the Rocky Mountains,' by Frank D. Adams and W. J. Dick, published by the Commissioner of Conservation, Ottawa, Canada, 1915.

DIVIDENDS paid by American mining companies in 1915 totaled $75,383,387, compared with $60,323,529 in the year 1914.

Emergency Repairs for Rock-Drills

By Wm. H. Washburn

At a mine at Sealevel, Alaska, the pistons and cylinders of the rock-drills became worn, and leaked so much air as to seriously impair their efficiency. The necessary repair-parts could not be expected to arrive within a month owing to the delays incident to distance, which included 700 miles of steamer-transport from the source of supplies. Meanwhile, we undertook to make such temporary repairs as would tide us over. The pistons were of solid steel, without expansion-rings, and it was necessary to enlarge them to fit the cylinders. We procured some block tin from the cannery near Ketchikan. After cleaning one of the pistons thoroughly and dipping it in hydrochloric acid, it was immersed in melted tin, and we succeeded in making a coating, about ¼ inch thick, adhere to it perfectly. A lathe in which the tin-coated piston could be turned to fit the cylinder was now necessary. A piece of 1 by 6-inch iron was bent to the form, shown at *A*, for the frame, in which ⅝-inch holes were drilled and tapped at *bb* to receive the head and tail



AN IMPROVISED LATHE.

centres. These were held firmly in place by jam-nuts. On the head-centre was mounted a loose wooden pulley *B*, run by a belt, by which the piston was revolved by means of a lathe-dog, in the usual way, holes being bored in the pulley for the dog. Both centres being dead, and held solidly in place by jam-nuts, the piston was revolved without vibration, while being turned. A 1-inch slot was made in the base of the frame and the base-plank *D* from *a* to *a*, to receive the bolt holding the tool-rest *C* in place. The tool-rest was made of a piece of ⅜ by 3-inch iron, the end of the part resting on the base of the frame being split and spread, to make it more rigid. With this machine, the piston was turned by a hand-tool to a perfect fit. When the drill was tested in the mine, it seemed to work as well as new. The rest of the drills were then repaired in the same way, until they were all doing efficient work.

The tin coating on the pistons wore better than expected, being still in good condition, when the repairs that had been ordered arrived a month later. By setting up a movable support for the tail-centre, inside the frame, the distance between the centres was shortened, so we turned out several air-valves for the drills, to replace some that were worn, and not working well. These valves were made of tool-steel having several annular grooves in them, and were only 4 inches long. They proved satisfactory in operation. Later we found this home-made lathe to be useful at various times, when making minor repairs on other machinery.

Cannon are discussed in a recent issue of the interesting periodical *Through the Meshes*, published by a manufacturing firm at Cleveland. The 42-centimetre (16.53-in.) mortar, which no war correspondent has ever seen, is stated on the authority of a German officer to be as high as a six-story building, when the gun is elevated and ready for shooting. The caterpillar-tractor wheels are probably 30 ft. diameter. The so-called photographs of 42-cm. guns published in the newspapers are only the 30.5-cm. Skoda howitzer. Many people appear to believe that a cannon is aimed by sighting along its barrel; on the contrary, artillery fire can be directed only by a man possessing a thorough knowledge of trigonometry, geometry, and calculus. But the guns of today are not the first cannon of large bore. At Ghent, in 1411, a cannon of 25-in. bore, 18 ft. long, weighing 13 tons, was constructed of wrought-iron bars held together by iron rings. This fired a 700-lb. granite ball. In 1468 at Constantinople, 19-ton bronze cannon of 19-in. bore were used, to fire a stone weighing 600 to 700 lb.; they were so unwieldy that they had to be retained in one position, and were kept loaded for months at a time. With these cannon the Turks killed 126 sailors and nearly wrecked six British men-of-war in 1807, when Sir John Duckworth retreated from the Sea of Marmora. Previously, at the siege of Constantinople in 1453, Mohammed II, who conducted the siege, constructed a bronze mortar of 36-in. bore that fired a 600-lb. stone. A caravan of 60 oxen and 200 men worked two months hauling this gun 150 miles to the scene of action. The trial shot hurled the stone a mile and buried it six feet in the ground. This ponderous cannon could be loaded and fired only seven times per day, but finally it became overheated and burst. At Waterloo, 101 years ago, the artillery range was but 1200 yards at the beginning of the battle, and only 200 yards before the battle was over. In Nelson's day, firing at a range of 1000 yards at sea was considered an extreme distance.

Salt Lake City has a population of 100,000, an altitude of 4250 ft., and is ten miles from Great Salt Lake. When the city was founded in 1847 by the Mormons, two years before the gold rush to California, the whole plateau region lay far beyond the advancing wave of western civilization, and the settlement was an isolated oasis in a vast desert. Today the city is an important centre and distributing point for mines in Utah, eastern Nevada, and southern Idaho. Great Salt Lake is 6½ times 'saltier' than the ocean, containing 22½% of solids.

Leaching Copper at the New Cornelia, Arizona

The following notes are from the report of the general manager of the Calumet & Arizona Mining Co., J. C. Greenway, for 1915. They refer to results of experiments conducted during the past 18 months on the oxidized copper ore at Ajo, and briefly describe the large leaching-plant that is being erected to treat 20,000,000 tons of 1¼% copper ore.

Process work was continued throughout the year. A 40-ton experimental plant was completed on January 31, and immediately put in operation. To December 31 there had been leached 291 charges, or approximately 12,222 tons. There were two distinct periods in this work. The first was from the starting of the plant on February 1, to charge No. 81. It was then decided to waste the entire supply of the solution in the system and begin with new solution. Charges No. 82 to 90, inclusive, were discarded. The second period began with charge No. 91 and continued throughout the year.

Results for the first period were as follows:

Average heads, copper per cent	1.248
Average tails, copper per cent	0.294
Average extraction, per cent	74.4
Average pounds per kw. h.	0.72

The second period gave the following results:

Average heads, copper per cent	1.337
Average tails, copper per cent	0.256
Average extraction, per cent	80.6
Average pounds per kw. h.	0.958

The 1-ton plant was operated from August 8, 1914, to November 3, 1915, with the following results:

Average heads, copper per cent	1.325
Average tails, copper per cent	0.283
Average extraction, per cent	79.0
Average pounds per kw. h.	1.125

In the belief that these results amply justified the immediate construction of the permanent plant, an appropriation of $4,200,000 was recommended in December to the directors and was granted.

The construction work now under way, and which, when completed, will put the New Cornelia property on a production basis of 36,000,000 lb. of copper per year, may be briefly described as follows:

This mine will be opened so that three 100-ton steam-shovels can be used for loading the ore into cars. The ore will be hauled approximately one mile to the treatment-plant, where it will be dumped directly from the cars into a large gyratory-crusher. Five 70-ton switch-locomotives and fifty 20-yard side-dump cars will be used on this mine service and ore-haulage.

The coarse-crushing plant will be equipped with one No. 24 gyratory-crusher, four No. 8 gyratory-crushers, driving-motors, and an electric traveling-crane.

From the coarse-crushing plant, the ore, reduced to about 3½ in., will be conveyed to the fine-storage bins having a storage capacity of 10,000 tons.

From the storage-bins the ore will be conveyed to the fine-crushing plant, where it will be reduced to ½ in. This plant will contain 12 Symons disc-crushers and an electric traveling crane, with the necessary motor equipment. An ore-sampling plant will be erected between the fine-crushing plant and the leaching-plant.

From the crushing-plant, the ore will be conveyed to the leaching-vats, where it will be bedded in even layers through the tank being filled. There will be 11 lead-lined leaching-vats, each 88 ft. square by 15 ft. deep inside, having a capacity of 5000 tons of ore each, and one sludge-tank of the same dimensions. Each vat will have its pumping equipment for circulating and advancing its solution at the rate of about 8000 gal. per minute. The leaching-vats will be arranged in two rows with a central structure between, which will support the conveyors carrying the ores to them, and the circulating pumps and necessary launders. After the copper is extracted from the ore and the tailing washed and drained, it will be loaded into cars by an excavator of the Hulett type. The tailing will be hauled to the dump in side-dump cars on the afternoon shift, the cars and locomotives used at the mine on the morning shift being available for this service.

This plant will have five wash-water and acid-solution storage-tanks of 430,000 gal. capacity each.

The neutral solution from the leaching-plant will be pumped to four sulphur-dioxide absorption-towers, approximately 20 ft. diam. and 40 ft. high, for the reduction of the ferric iron to suit the requirements of the electrolytic plant. From the absorption-towers, the solution will be pumped to the electrolytic-plant, where it will be circulated through the electrolytic-cells and the acid solution returned to the leaching-plant. The tank-house will consist of two main aisles each 80 ft. wide and 270 ft. long, and will contain 152 lead-lined electrolytic-tanks approximately 30 ft. long, 4 ft. wide, and 5 ft. deep, with the necessary cranes, pump-circulating equipment and sumps.

The power-plant building will be of steel and concrete, approximately 126 ft. wide by 200 ft. long. The boilers and turbines will be in the same building, but separated by a partition. The boiler-room will contain five 822.6-hp. Stirling boilers set for oil-firing, economizers, and feed-water equipment. The turbine-room will contain two 7500-kw. steam turbines, the motor-driven direct-current apparatus for the electrolytic-plant and the switchboard.

The plant will be provided with a water-storage tank of 300,000 gal. capacity at a suitable elevation. Two oil-tanks of 15,000 bbl. capacity each, and four acid-tanks of 150,000 gal. will be provided and arranged with reference to the unloading tracks so that oil and acid will flow by gravity directly from the cars to the tanks.

Further work will be done in water development, and an electric-driven pump, with a capacity of 750 gal. per minute will be installed at No. 1 well. A 10-in. pipe-line will be laid from No. 1 well to the storage-tank at the plant. A general office and laboratory will be added to the plant.

CONCENTRATES

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

GOLD-AMALGAM from the Brunswick mill, Grass Valley, California, yielded 39.3% gold in 1915. In crushing 22,004 tons of ore, 12,046 oz. of quicksilver was fed to the batteries.

MALAPAI, the name given in Arizona to the dark volcanic rock, usually in the form of lava-flows, capping a *mesa*, is a corruption from *malpais*, meaning bad lands, from the Spanish *mal*, bad, and *pais*, country. The rock is generally a variety of basalt.

SHAREHOLDERS are free to re-locate mining claims abandoned by their companies. A shareholder does not stand in the relation of trustee to his fellow shareholders, but a director or other officer of the company does stand in that fiduciary position and therefore cannot relocate a claim under such circumstances. This has been decided by the courts.

IN LOCATING mining claims on lands within the limits of railroad grants, it must be kept in mind that if railroad patents have already been issued, these patents are controlling until set aside in appropriate proceedings brought usually on the part of the United States Government to cancel such patents on the ground that they have been issued through fraud, mistake, etc. There is also a time limit and such patents can not, in the absence of fraud, be attacked if 6 years have elapsed after the date of the issuance of the patent. As to whether fraud on the part of the railroad company suspends the running of the statute is a question now before the Supreme Court of the United States for determination.

LABOR LIENS. A correspondent refers to the case of Dahlman *v.* Thomas, 153 Pac. 1065 (Wash.) This case held that the owner of mining property was liable for liens for labor performed at the instance of persons holding an option on the property, even though the option contract was recorded and a notice posted on the mine in the name of the owner, disclaiming liability. The case held in substance that where the owner benefits by the improvements placed upon the mine in pursuance of the terms of the option, that this provision practically makes the prospective purchaser the agent of the owner. This case was decided December 18, 1915, by the Supreme Court of Washington on an appeal from the Superior Court of Whatcom County, Hon. Ed H. Hardin, Judge.

TUNGSTEN DETERMINATION by a quick method is that of W. L. Faust of Deadwood, South Dakota. He uses a fusion-powder containing potassium chlorate, potassium nitrate, sodium carbonate, and sugar. Taking about 1 gram of this powder, mixed with an equal amount of crushed ore (if the ore is low grade using pannings) an almost instantaneous fusion is effected by applying a match. The result of the fusion is a granular mass, which is rubbed a moment in an agate mortar, then placed in a test-tube with hydrochloric acid and sheet or granulated-zinc. A little boiling will yield a blue-colored solution if tungsten is present. The test is one that can easily be made in the field; the equipment necessary to conduct it can be carried in a coat-pocket and it no doubt will be widely used by prospectors.

MERCURY occurs in Cobalt, Ontario, ores according to investigation by G. H. Clevenger in *Economic Geology*. It was first identified there in 1910, during experiments in treating the high-grade silver ore, when something interfered with accurate estimations. When the Nipissing refinery was completed, and the first charge treated, the mercury collected in the flue convinced skeptical metallurgists and others that the metal did exist in the ore. Twenty-two determinations on Nipissing ore yielded from 0.26% in certain ore to 4.74% in nuggets, one La Rose nugget yielded 1.34%, one nugget from the Coniagas jigs gave 1.48%, leaf-silver at the Chambers-Ferland 0.8%, and O'Brien tetrahedrite 0.5 to 0.58%. Generally the purer forms of leaf silver contain less mercury than the more impure nuggets, containing more antimony. Individual masses of the metallics show considerable variation in the percentage of quicksilver, but ore mixtures as treated in the mill show a far more regular content. It seems that mercury occurs as an amalgam, rather irregularly distributed in the metallic portion of Cobalt ores, with a tendency for the dyserasite to contain more quicksilver than the purer forms of silver.

MINERAL LANDS. There was a period of time when considerable doubt existed as to the application of the words, "mineral lands," contained in the railroad grants. The Department of the Interior was at first inclined to the view that this term used in the reservation clauses applied only to the more valuable metals. The question however has been set at rest by the Supreme Court of the United States, which has held that "mineral lands," as used in these Acts, "include not merely metalliferous lands but all such as are chiefly valuable for their deposits of a mineral character, which are useful in the arts or valuable for purposes of manufacture." The case in which this question arose involved a deposit of granite, and this substance was included in the general category of building-stone, and the Land Department has held that marble, slate, limestone, and sandstone come within this classification. Lands containing these deposits to be exempted from the railroad grants must contain the substances in such quantity and value that they are the subject of location under the mining laws. The Land Department has frequently applied the test that they must be of special value as distinguished from the surrounding country. In other words, a location of granite in territory where the entire surrounding formation is granite, would not satisfy the requirement of a mineral deposit of special value, sufficiently to justify a mining location.

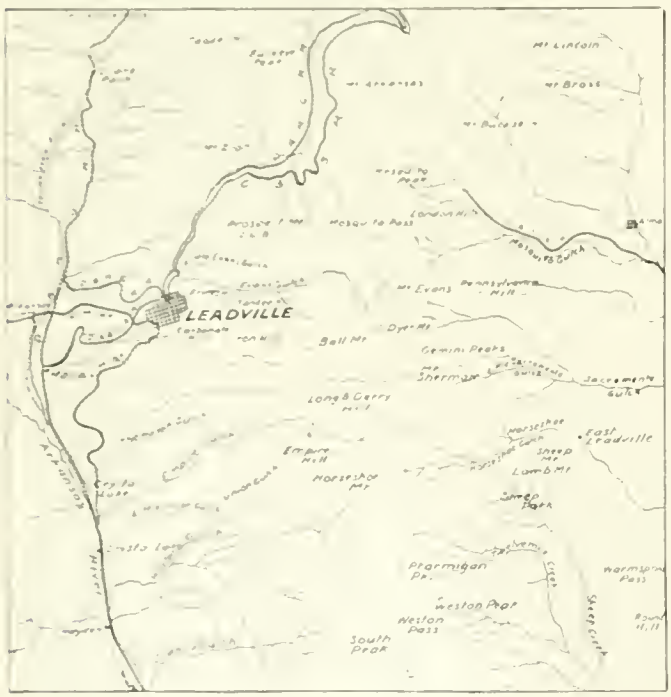
REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

LEADVILLE, COLORADO

PROGRESS AT THE HARVARD.—FLOTATION AND HIGH METAL PRICES REOPEN THE ALICANTE AND WILSON MINES.—ELLA BELLER, RUBY, LITTLE ELLEN, AND THE SILVER KING.

The Leadville Unit of the United States Smelting, Refining & Exploration Co. began pumping through the Harvard shaft on Fryer hill at noon on March 20. Delivering 1500 gal. per minute, the pumps are gaining an average of 12 ft. a day on the water. The shaft is 407 ft. deep, and before pumping the water-level stood at the 240-ft. mark, leaving 167 ft. to be drained. At the present rate it would require only two weeks to unwater the property, but as water is lowered the efficiency of the pumps is decreased. Draining of the immense stopes



THE LEADVILLE DISTRICT, COLORADO.

and other workings will also retard the lowering of the pumps in the shaft. The manager, H. S. Lee, and superintendent, E. H. Hamilton, estimate that it will require 90 days to drain the workings, providing that all connections with adjoining shafts are open and will allow free passage of water. Otherwise progress will be somewhat slower to avoid danger from rushes of water through partly drained levels. Sinking the Harvard shaft several hundred feet through the parting quartzite into the second contact is expected to commence on July 4. Meanwhile a campaign of thorough exploration will be carried on throughout the territory controlled by the Leadville Unit. As the water is lowered, the workings in all of the shafts in the area will be examined, samples will be taken of all ore exposures, and a comprehensive geological map will be made. Should any orebodies of value be encountered in this campaign, shafts on which they occur will be equipped with machinery. The surface plant at the Harvard will also be completed while pumping is in progress. A new air compressor is being installed for sinking. A large double-drum hoist, with a lifting power of 5000 lb. at the rate of 400 ft. per minute has just been put on its foundation, and will soon be ready. A complete machine-shop is being equipped, and a permanent pumping plant for the bottom station is being assembled.

The quick work of Mr. Lee in getting started at the Harvard has aroused admiration among local mining men. It took just 44 days to erect a surface plant, repair the shaft, cut a station, install machinery, and get the pumps in operation, all in severe and stormy weather.

The Denver Mining & Milling Co., with E. T. Miller and O. H. Cold as manager and superintendent, has taken a long-term lease and option on the old Alicante property near Wortman, on the main line of the South Park branch of the Colorado & Southern, about 10 miles north of Leadville. The property was more recently known as the John Reed, and was operated by the Burma Mining & Milling Co. several years ago. The Burma company did extensive development in the mine, sinking a shaft of 150 ft. and driving over 500 ft. on the vein. A huge deposit of low-grade lead-zinc ore was opened, and a large mill equipped with rolls and Wilfley tables was erected. This process did not prove successful under the prices offered for the concentrate at that time, and the property was abandoned. The new company from Denver is now installing a complete flotation plant in the mill, a process that has been found to be highly efficient in concentrating the ore. Three carloads of machinery have been unloaded at the siding, which was recently put in to the mill from the main line. The adit will be equipped with modern machinery, as all work will be done through it. The preliminary work is being rushed, and the management reports that the property will be operating early in April. Mining men familiar with the John Reed state that it is one of the biggest low-grade lead and zinc properties in the district. The present metal market is so much higher than that prevailing when the mine was last operated, that the ore cannot now be considered low-grade. With a flotation plant for concentration, the property promises to be one of the most successful in the district. The mill has a capacity of 200 tons per day.

The Progress Mining & Milling Co., an Eastern concern, has taken over the Wilson mine and mill near Robinson. William B. Brooks, one of the early-day mining and milling men of the Leadville district is manager. A large tract of mining land has been secured in connection with the Wilson property, and operation will be on an extensive scale. The ground controlled by the company is rich in lead and zinc ores of comparatively low grade. The Wilson, which is 1400 ft. deep, has been one of the heaviest producers of lead-zinc ore in the district, and when last operated large bodies were exposed. A 250-ton mill stands on the property equipped with Wilfley tables and rolls, a combination that was extensively used throughout the country for concentrating low grade lead-zinc sulphides. This plant is to be replaced by flotation machines that are now being installed in the mill. Mining will be done through the Wilson and Columbus properties, where immense bodies of ore are easily accessible. The company will produce 250 tons daily. An office has been opened at 120 East Chestnut street, Leadville.

Charles J. Moore, well known in the West, and formerly consulting engineer for the Portland company at Cripple Creek,

is preparing to operate the famous Ella Beeler property near the head of Iowa gulch. Mr. Moore has been associated with mining in the Leadville district for a number of years, and is familiar with the Iowa gulch area where he has operated other properties in the past. The Ella Beeler is one of Leadville's historical properties. In the early 80's the Carlton brothers operated the mine with great success. At that time some of the richest lead and silver ore that has ever been mined here was taken from the Ella Beeler. The ore was found close to the surface, and there never has been extensive development below 300 ft. Mr. Moore will do some deep mining. All of the ore-shoots have been traced to water-level, and there is no doubt that large bodies of rich silver and lead will be opened, following the draining of the mine. A strong company has been organized to finance the undertaking, and it is planned to have the work underway early in April.

The Lanyon Zinc Co., a Colorado mining and milling corporation, composed of a number of well-known Leadville and Denver mining and business-men, has undertaken extensive operations throughout the Leadville district. During the winter the company has been working the Ruby property in the Weston Pass district, where one of the largest zinc carbonate mines in the State has been developed. The Ruby is now equipped with a complete pumping and surface plant and is prepared to operate on a large scale. Several large veins of carbonate have been opened, varying in width from 3 to 7 ft. The ore is all high grade, averaging around 40% zinc. Fifty tons a week has been shipped all winter, but a much larger output is planned for the coming spring and summer. The Ruby is 10 miles from the nearest railroad siding at Hayden, and it has been a difficult task to keep the wagon-road open throughout the winter. Transportation of ore by motor-trucks is being considered by the company, and it is possible that this system will be tried during the summer.——The Little Ellen property near the head of South Evans gulch has also been taken over by the Lanyon company. Prospecting is now in progress, and present indications point to the opening of another large zinc producer. The mine has been one of the rich producers of gold, lead, and copper ores and more recently, zinc carbonate.——The Silver King on Yankee hill, and the Modoc on Carbonate hill are now controlled by the Lanyon company, and the work of cleaning-out the mines is now under way. On the Silver King several promising veins of zinc carbonate have been opened in the adit, which is about 300 ft. into the hill. These veins dip away from the workings, and preparations are being made to sink an interior shaft on the ore.

MEXICO CITY, MEXICO

FRANCISCO VILLA: HIS TRIUMPH AND HIS DOWNFALL.

Now that Villa has the honor of being hunted by a large part of the regular army of the United States, it may be of interest to mining men—always compelled to be students of native psychology and politics—to review the events that have degraded Villa from the triumphant revolutionist of January 1915 to the common fugitive from justice of today.

At the Aguascalientes military convention of October 1914, when Villa found that even his alliance with Zapata had not given him a majority of delegates, he moved his army closer, and obtained by intimidation what was impossible by persuasion, namely, the election of his candidate, Eulalio Gutierrez, as provisional President. Gutierrez, before becoming a revolutionary 'general' had been a foreman in the mines of Bonanza, Zacatecas. Though without formal education, he was intelligent, and his long service with foreign companies had taught him the advantages of wisdom, sobriety, and honesty—qualities rare in Mexico. Therefore, when he arrived in Mexico City in November 1914, to organize the government, he announced his intention of "moralizing" the Revolution, and selected for his cabinet some of the most honorable and best educated Liberals he could find. The new government functioned smoothly, until Gutierrez found that "morality" did not suit Villa, who was blithely pursuing his own ways of vengeance and pillage in the capital, and regarded the President as merely a convenient marionette. When matters came to a show-down, Villa controlled the army and Gutierrez only saved his head by a flight to San Luis Potosi with a few thousand of his personal troops in January 1915. Owing to disaffection among his northern garrisons, and lack of ammunition for his army and oil for moving his trains, Villa left Mexico City soon after Gutierrez, abandoning the "sovereign" Convention and the capital to the hordes of Zapata, which were then also holding Puebla City and the whole region west to the Pacific coast.

When Carranza withdrew from Mexico City, in November 1914, his cause was apparently lost. But Fortune had not really departed; she had only made herself invisible. He still had the cannon taken from the Federal arsenals of the capital, and the rifles, ammunition, uniforms, and other equipment secured from the mustering-out of the Huerta army in September 1914. Moreover, he had thousands of horses, looted from everywhere, and hundreds of automobiles, mostly lifted from their owners in Mexico City. But best of all he controlled Tampico, which furnished the only motive power of the railroads, and, by sending an ultimatum, he got Bryan to abandon Vera Cruz city and thus secured the chief source of customs revenue in the country.

The two leading generals who had adhered to Carranza were Alvaro Obregon and Pablo Gonsalez, in charge of the Northwest and Eastern army divisions, respectively. And Carranza's reviving strength was shown at the opening of 1915 by the capture of Puebla City on January 5 and of Mexico City a month later by the forces of Obregon. During February, Obregon gave the capital a "castigation" for its dislike of Carranza, which culminated with his enlistment of 5000 skilled workmen from the local branch of the Casa Mundial (I. W. W.) and their shipment, along with thousands of their wives and children, to Orizaba to form the Red brigade.

The subsequent career of the Red brigade was both comical and bloody. Sent to garrison Tampico, after a little drilling at Orizaba, it soon was tempted to attack the Villistas at Ebano, an oil town some 30 miles west of the port. Composed as the brigade was of the butchers, bakers, and candlestick-makers of the capital, who, like the mass of Mexican City workmen, are alcoholic degenerates, it soon fell into a panic when it encountered the disciplined villagers of General Tomas Urbina, who defended Ebano. The panic resulted in flight, hundreds being cut down by Urbina's pursuing cavalry before reaching the port.

In early March, General Obregon evacuated the Capital and moved his army north-west along the Central railway to attack Villa. Pablo Gonsalez, with his eastern division, was left as a rear-guard to keep open communications with Vera Cruz, by way of Pachuca and the Mexican railway; but Mexico City and its connecting railways, nearly as far east as Ometusco, were abandoned to Zapata.

Obregon, with his army of some 14,000 men reached Celaya without trouble, but there he was attacked by Villa with a larger force. But Villa's famous Northern division was not the same army that drove Huerta from Torreon and Zacatecas. Thousands had been killed in those bloody sieges and their places taken by degenerate city recruits. On the contrary, Obregon's army included 6000 Yaqui and Mayo Indians, the best rifle-shots in Mexico, and thus it was able to repulse the attacks of the larger Northern division, even though led by Villa himself.

After the drawn first battle of Celaya, Obregon heeded the request of the foreign consuls and moved his army to some hills outside of town. Here he was soon attacked by Villa, whose army had only retired a few miles west along the Central railway. In this attack on Obregon's chosen position, Villa

fell into a trap and, having lost 3500 men and half of his 60 cannon he was obliged to beat a hasty retreat toward Leon, where he had left General Angeles with a small army as a rear guard.

The truth was that success and much newspaper notoriety had turned Villa's head and, after the fall of Huerta, he had got to imagine himself to be, what his flatterers dubbed him, the Mexican Napoleon. Jealous of the real cause of his success, Felipe Angeles he had deliberately left him behind in the Celaya campaign. After his defeat, Villa recalled Angeles and most of his northern garrisons and finally mustered an army of some 40,000 men near Leon. Obregon meanwhile had been busy and by drawing the armies of Generals Dieguez and Murguia from Guadalajara and several brigades from Vera Cruz he was able finally to equal the number of his enemy. But Villa had the advantage of position, for he had Obregon shut up in Trinidad, the first station east of Leon, and for a week (of the five weeks that the siege lasted) had his communications cut with the Gulf coast.

Though Angeles had Obregon surrounded he was able to do him but little damage, owing to the lack of the cannon lost by Villa at Celaya. Nevertheless, Villa became impatient at the want of results, and had Angeles arrested for incompetence and threatened to shoot him. Diverted from this insane idea by his friends, Villa soon released Angeles, but the harm had been done. The insulted general at once resigned his command and left for the United States.

With Angeles went also his Yankee gunners and with them departed Villa's last chance of victory. Though Villa had still many ex-Federal officers, with a military education, while Obregon had practically no officers but self-taught ones, the autocratic methods of the former negatived the superior skill of his personnel, while the latter never made a move without a council of war.

Obregon now bided his time, and one May morning at dawn he succeeded in surprising Villa's troops in their trenches and in capturing a large part of their cannon and equipment. Next day he entered Leon in triumph while Villa's demoralized army was in full retreat by train toward Aguascalientes.

The defeat at Trinidad broke the power of Villa; it not only lost him his cannon and many of his best veterans, but destroyed his halo as an "ever-victorious" which had previously drawn to his colors thousands of hardy Mexican Liberals and bandits, and many foreigners. His contempt of law and of anyone's "democratic rights" except his own, which had been so glaringly evident in his controversy with President Gutierrez, had already alienated much of his Liberal following, and after his defeat, the purely mercenary also began to leave him. Now, reduced to a following of a few thousand, Villa has turned like a wild bull at bay and raided the country whose adulatory press first discovered his "greatness" and thus caused his later ruin. The entrance of Uncle Sam's soldiers may pacify the North and enable mining to resume. Would that the South, too, could also be similarly pacified!

DEADWOOD, SOUTH DAKOTA

High Tungsten Prices.—Mineral Exhibition.

A new record was set in the value of tungsten ores in the Black Hills, when on the 17th the Wasp No. 2 Mining Co. sold 19 tons of mixed-grade ores for $83 per unit. The carload was valued at over $90,000. A few tons of hand-sorted ore, and three grades of concentrates—35, 45, and 65%—made up the lot. This shipment was the result of a little more than a month's actual operation of the new concentrating plant. This started on January 6, and on account of various difficulties, such as the failure of a ball-mill, which had to be replaced, a shortage of water for a few days, and some changes in the treatment method, such as the abandonment of jigging, lost considerable time. The low-grade dump which had been accumulated from hand sorting of high-grade ore, has nearly all been put through the concentrator, and the plant will in the future be operated largely on ore blocked out in the mine.

A feature of the fourth annual auto-show at the Deadwood auditorium is the mineral exhibit. This includes all classes and character of Black Hills ores and mineral products, well arranged. Not the least interesting feature is the exhibit of Kirk G. Phillips estate, dealers in assay and mill supplies. At this booth, in charge of W. L. Faust, demonstrations are made of his quick method for determining tungsten, published on the 'Concentrates' page of this issue.

TUCSON, ARIZONA

Tungsten Deposits in Pima County, Production, Testing.

Tungsten ore has been developed over an area four miles long by more than a mile wide in the Arivaca district of Pima county. The veins, of which there are three principal ones, and many subsidary stringers, strike east and west, and are continuous throughout the length of the tungsten bearing area, finally disappearing beneath the alluvial on the west and continuing east into a gold-bearing area. The principal veins have been prospected by trenches and shafts, at varying intervals, for a distance of three miles, showing a high proportion of good shoots. Development at present is confined principally to those largest and richest shoots, of which there are five.

These vary in width from 2 to 8 ft., and from 50 to 100 ft. in length. To the greatest depth attained, 150 ft., they retain their width, and are continuous.

The National Tungsten Co. of Tucson owns practically the entire area, and has made regular shipments of from 10 to 15 tons of concentrate for the past 8 months from its Las Guijas mine, managed by Arthur L. Kelley. The mines are as yet only mere prospects, and the mill is still in the experimental stage. The product has maintained a $10,000 monthly payroll, besides furnishing supplies and equipment necessary for operation. The geological features are much the same as those of other districts containing tungsten, namely, the country rock is a coarse-grained biotite-granite, with its accompanying fine-grained acid rock, with some diorite dikes, which are intimately associated with the veins and vary from a few inches to 40 ft. in width. North and east of the granite area is andesite breccia and limestone, in contact; south and west lies a desert of 20 miles to the Baboquivari range, also granite.

The tungstates of commercial importance are those of iron and manganese, in the minerals wolframite and hübnerite. Some stolzite is present, but only discernible at times as a gray thread-like streak on the concentrating tables. Pyrite and chalcopyrite are at times more or less troublesome, and silver, up to 50 oz. per ton has been found in specimens, these being as high as $5 per ton in gold. But the precious metals have not been found in commercial quantities. Some ferberite has been brought in for sale by Mexicans, showing that there are deposits of this mineral within a reasonable distance.

Chemical analyses of the ores for their tungstic-acid content are satisfactorily made at the plant by the method given in J. Ohly's 'Analysis, Detection, and Commercial Value of the Rare Metals,' as follows:

Quantitative determination.—Reduce the ore to a very fine powder, weigh off one gram and digest for 12 hours (over night) at a gentle heat with a mixture of four parts hydrochloric and one part nitric acid, till yellow pulverulent tungstic acid remains. Evaporate to dryness on water-bath, and take up with water acidulated with hydrochloric acid. Filter and wash the residue, consisting, besides the yellow trioxide, of silica and sometimes small quantities of niobic acid, with alcohol, and treat the mixture on the filter with ammonia. Place the filtrate in a large weighed porcelain crucible, evaporate to dryness on the water-bath, and heat the residue of ammonium tungstate to decomposition. Weigh the crucible with the remaining trioxide and calculate the percentage.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

Fairbanks

The 10-stamp mill at the mouth of the Chena river is to crush tungsten ore from Johnson and Ewers' mine on Gilmore creek.——Considerable tungsten occurs in the Ott Mining Co.'s property on Fairbanks creek. When the ore is low in gold, it is high in tungsten, and vice-versa.

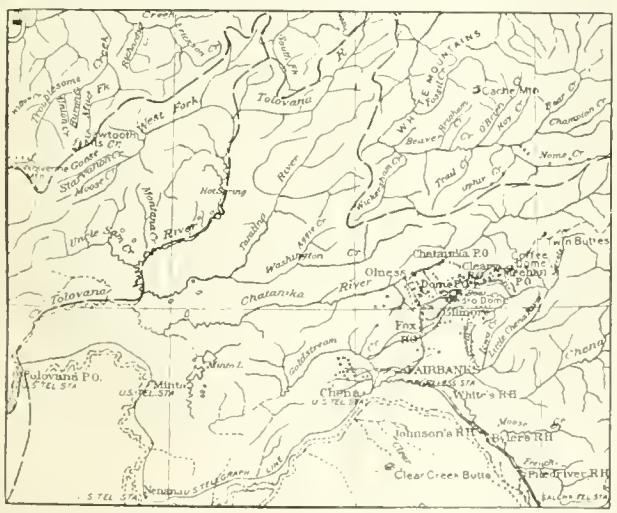
Juneau

February returns of the mines on Douglas island are as follows:

	Mexican	Treadwell	United
Ore crushed, tons	17,535	68,796	43,939
Gold yield	$22,118	$107,557	$84,116
Average per ton	$1.26	$1.56	$1.91
Operating expenses	$25,193	$100,830	$72,307
Construction expenses	10,542	8,256	14,680
Loss	13,838	2,605	3,702

Valdez

The Granite Gold Mining Co., which owns and operates properties near Valdez, will commence dividend payments in April, when 2c. per share, or $8600, will be disbursed, according to official announcement. The capital is 500,000 shares at



GOLD-BEARING CREEKS IN THE FAIRBANKS DISTRICT, ALASKA.

$1 each, of which 304,000 shares are issued. The company's holdings comprise three 20-acre claims, covering the vein for 3000 ft. Equipment consists of a 180-hp. oil-burning engine and a 150-hp. electric generator, together with switch-boards, water and oil pumps, and fuel-storage tanks. The generating-station is connected with the power-plant at the mill by a 4800-ft. transmission-line, providing current for a 100-hp. motor, which operates the compressor and auxiliary machinery. The concentrator includes a 10-stamp Hendy mill and a 7-ft. Lane mill, both motor driven; two crushers and one set of rolls, etc. A 4000-ft. corduroy road connects the mine and mill with the wharf at Hobo bay, and the camp is provided with buildings to comfortably house and care for 60 men. The company also owns a 60-hp. gasoline-launch and an 80-ton barge. There are four levels, from 300 to 500 ft. long, opened in the property, and recent reports state that the lower adit has been extended to cut the vein at 800 ft. vertical depth, materially increasing the ore reserves. The mill now is treating 60 to 70 tons daily, and about 50 men are employed. B. F. Millard, Valdez, is president, treasurer and general manager of the company; W. R. Millard, also of Valdez, is first vice-president and superintendent; O. S. Larson, Seattle, is second vice-president; and J. W. Gilson is secretary.

ARIZONA

Gila County

(Special Correspondence.)—The American Smelting & Refining Co. intends spending $160,000 in improvements to its smelter here. At present the company is building a sampling-mill with a capacity of 75 tons per hour, to cost $40,000, as well as an ore-bin, capable of holding 7000 tons. Both are near the present plant, and are to be finished by July. Further improvements to the plant covering the remainder of the appropriation will be made in the near future.

Hayden, April 1.

At the Inspiration mill work is under way on the tailing-dam. The site has a capacity for many years' work.

During 1915 the Arizona Commercial Mining Co. produced 44,353 tons of ore, yielding 3,592,274 lb. copper, 16,512 oz. silver, and 283 oz. gold. The revenue was $439,412, and profit $211,775, of which $31,293 was written-off for depreciation. Including the previous balance the surplus is $473,715. A power-plant costing $75,000 is to be erected. Development on No. 14 level is excellent.

Mohave County

(Special Correspondence.)—The following news of the Cerbat, Stockton Hill, and Todd Basin districts in the Wallapai district, from 12 to 15 miles north of Kingman, should be of interest:

The Charcoal Canyon Mines Co. has purchased the Marion group and the Ryan zinc group of claims from the Ryan Cattle Co., and will commence development in the near future. Shafts will be sunk at three places. High-grade zinc has been found in the shaft, and indications on the surface point to large bodies at depth.

The St. Louis mine has been taken over by R. C. Billings and associates. Driving an adit on the vein is in progress, and ore is being sacked for shipment, the value is mostly in lead and silver.

The Champion mine is making shipments of lead and zinc ore, extracted by lessees.

The Arizona Butte Co., on Stockton hill, is placing an order for mining and milling machinery. It has an immense amount of milling zinc and lead ore blocked out in the mine.

The Middle Golconda in Todd basin has cut high-grade ore in a cross-cut adit. The vein is said to be over 50 ft. wide, with the hanging wall not yet in sight.

The Golconda Consolidated Mines is working its mill on ore which is said to be in keeping up to the average of the mine, $10 to $14. Mr. Miller of the California Corporation Commission recently examined the properties of this company, and was favorably impressed.

Kingman, March 19.

Since August 1915 nearly 200 companies have been organized

to operate in the Oatman district. About 100 companies are fully equipped, 50 are in the stake where they are receiving machinery, the remainder either have their machinery or declare or will place their orders at an early date.

A larger hoist is being installed at the United Western. This will handle rock and the water encountered at 505 ft. The southwest cross-cut at this depth is in 285 ft., and in the last 50 ft veins up to 24 in. wide, worth $5 to $16 per ton, were cut.——A 40-hp. hoist, 50-hp. Fairbanks-Morse oil engine, 5-drill Ingersoll compressor, drill-sharpener, etc., has been purchased for the Oatman United.

The Big Jim company has sold 200,000 shares at $1.75 each. The buyer's name is not yet known.

ARKANSAS

Marion County

The new 250-ton per 10-hour shift mill at the Bear Hill mine is in operation; it is modern in every respect. Ore is extracted at a depth of 90 to 160 feet.

A market for 20% calamine ore has been opened at Yellville by W. J. Fene.

CALIFORNIA

Humboldt County

It is reported that there is a revival in black-sand treatment for platinum along the beaches north of Eureka, and up in Oregon.

Mariposa County

(Special Correspondence.)—The Early mine, near Jerseydale, a property with a good past gold production, is being reopened by Mrs. N. C. McIntyre. An old drift has been reopened, a shaft sunk 100 ft. below it, and development started both ways from the shaft's bottom. A fair width of good-grade ore is being driven on. Litigation is hindering work at this promising prospect.

North-west of Mariposa is the Colorado mine, which is being developed slowly but thoroughly. The vein is yielding up to $9 per ton in the 10-stamp mill.

Jerseydale, March 27.

Nevada County

The Golden Center company is interested in a 60 days' option on the Allison ranch in the Grass Valley district. This property has yielded a great deal of rich ore.

Sacramento County

No. 7 dredge of the Natomas company sank on April 1.

San Bernardino County

There is unabated interest in the new Goldstone district, according to news from Barstow.

The new interstate bridge across the Colorado river below Needles was formally opened for traffic last week. It is on the line of the old Trails national highway.

Shasta County

According to M. E. Dittmar, manager of the Green Horn mine, near Tower House, shipments this season to Kennett should yield up to 50,000 lb. copper per month.

Trinity County

In the annual report of the Crown Reserve Mining Co. of Cobalt, Ontario, the following remarks are made by the general manager, Samuel W. Cohen:

"An exploration and examination campaign was vigorously prosecuted, and, as a result, one property located in Trinity county, California, was taken under lease by the Globe Consolidated Lease Incorporated Co., in which we own the control. This property consists roughly of 2500 acres of mining lands, together with water-power, timber, and other rights necessary for mining. The property is fully equipped with a modern cyanide-mill, saw-mill, machine-shop, power-house, etc., and everything necessary for the complete operation of a mine of about 150 tons per day. The property has produced about $650,000 of ore of an average value of $10. Inasmuch as the property is a going concern, and there is a 1500-ft. ore-shoot with an average width of 6 ft. and value of about $9, from above which all the gold has been produced and below which practically no development has been done, there is every reason to expect a favorable future for the property, which was acquired on advantageous terms."

Four hundred tons of material is to be hauled by A. G. Frost from Redding to Junction City for the Valdor Dredging Co., which is to erect a dredge on the Trinity river, four miles from Junction.

COLORADO

Clear Creek County

(Special Correspondence.)—The Climax mine on Columbia mountain has a promising development, an 8-in. vein having been cut, assaying 140 oz. silver and 0.6 oz. gold per ton. The ore was found 1500 ft. from the portal of the adit. J. N. Calder of Lawson is manager.——The Sunshine vein on Albro mountain, owned by C. W. Lurchen, has just been intersected by the adit, showing 10-in. of yellow copper ore. It is valued at $30 per ton in gold and silver.——Construction on the new mill to treat the ores of the Silver King mine at Dumont, will be started early in April. Hendrie & Bolthoff of Denver are owners.——The Skidoo mine, up north Spring gulch, is receiving attention by Chapman & Co. and shipments will commence as soon as the road leading from the property can be repaired.——W. A. Gilman, manager of the New Era mine at Freeland, states that shipments of smelting ore will be made at the rate of 100 tons a month. The ore averages $100 per ton in gold, silver, and lead.——The Engineers' Leasing Co., operating on the Gunnell mine through the Argo adit, is maintaining a heavy output of mill ore, the product being consigned to the Argo mill.——Work will shortly be resumed on the Lincoln company's holdings, situated on Lincoln mountain. The various levels are to be thrown open to lessees.——The Jackson 50-ton concentrating plant has been overhauled, and is treating ore from the Edgar mine.

Idaho Springs, March 28.

Teller County (Cripple Creek)

The March output was $1,227,810 from 86,672 tons of ore.

During 1915 the Doctor-Jack Pot Mining Co.'s properties, mostly leased, produced ore worth $277,433, making $3,810,000 to date. On January 1 there was $114,742 cash on hand.

Tungsten ore has been found at the old property of the Wolframite Gold Mining Co., several miles south of Cripple Creek, along the Florence & Cripple Creek line. The owners, F. Hackney and C. B. McHenry, shipped 300 lb. of 23% ore.

IDAHO

Idaho County

New York and Philadelphia capital is becoming largely interested in gold properties in central Idaho, both placer and quartz, and extensive operations are planned for the coming season, according to J. M. Hinton, a pioneer mining man of the Newsome-Ten-Mile district of this county. Mr. Hinton states that there is promise of greater activity in the Clearwater basin, as soon as weather conditions permit, than ever before, and he predicts that the season's output will be approximately $1,000,000 net. In the Newsome region there are several properties that have been practically idle for some months which are being re-opened, while those that have been operated at reduced capacity are being extensively developed with a view to increasing the output. The old Harmon and Morrow mine, the discovery of which created so much excitement several years ago, is being worked steadily, and new development is revealing orebodies that were not suspected to exist. The value is increasing with depth, and the shoots are becoming more extensive. The owners are glad that the

interests that had it under bond soon after it was discovered allowed the option to lapse. Smith brothers, operating the New York and Georgia claims with 15 men, recently opened a new 8-ft. vein in the lower adit that yields $15 per ton on plates. It is 80 ft. to the next upper level, and exploration has proved that the intervening ground is in the stoping area. They have shipped 700 tons in the last few weeks that returned $12,000, and there are 500 tons on the dump that assay about $10 per ton, which will be treated as soon as a concentrator, recently ordered, is installed. On the Wonder group, in which eastern men are interested, a raise is being put up on ore from the 400-ft. level, and the value is uniform throughout. Conditions in the entire district never were more promising, and the belief is general that the Northern Pacific railway soon will extend its line from Stites, the present terminal.

At the Una mine, Ora Grande, the main adit is in 900 ft., and nearly under the vertical shaft, which is in a wide vein of $7 ore.

Shoshone County (Coeur d'Alene)

The Bunker Hill & Sullivan company is producing 40,000 tons of ore per month, yielding 3300 tons of lead in concentrate, and employing 800 men in all departments. There are 500 ft. of cross-cuts and drifts on the level 1000 ft. below the Kellogg tunnel. These workings are at a vertical depth below the original outcrop of 2300 ft. and, following the dip of the vein, at an inclined depth of 3500 ft. The geological conditions on this level are normal, and give no indication of any change from the conditions that have prevailed throughout the entire depth of the mine. There is no perceptible variation in either the grade or character of the ore and no apparent change in the size of the orebodies, according to Stanly A. Easton, the general manager. The company also manages the Caledonia, Ontario, and Sierra Nevada. The Ontario produces 1000 tons of concentrate per month, and employs 150 men.

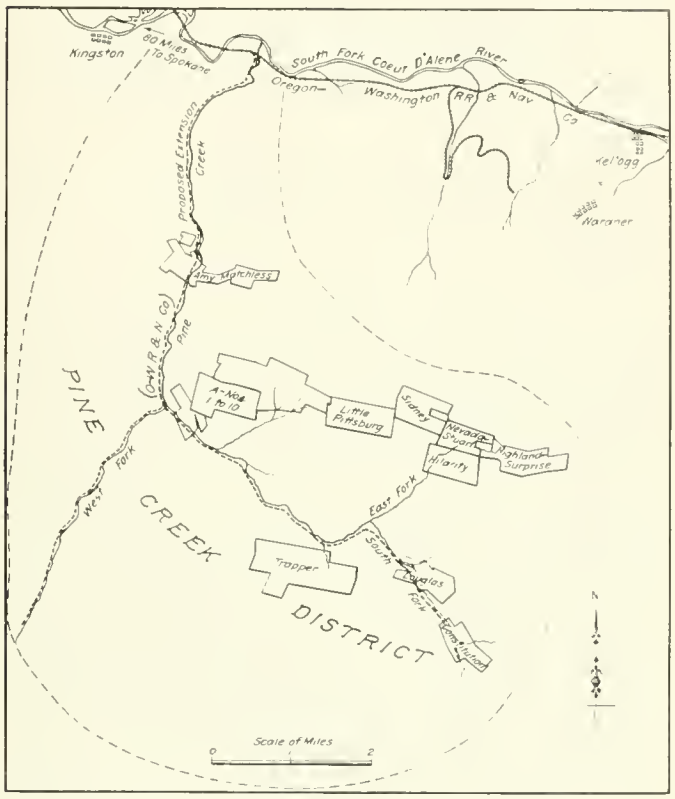
The new smelter for the Bunker Hill will be at Kellogg. Its daily capacity is to be 900 tons of ore and concentrate. Grading will be commenced in a few days, and construction will employ 500 men. It will be complete early in 1917. Some of the structural material has already been delivered, while contracts have been let for the remainder.

The Alice mine, adjoining the Morning at Mullan, has been re-opened under lease by Granville A. Collins and others of Seattle. The mine is well opened and equipped to supply the 150-ton mill with lead-silver ore.

According to Chester T. Kennan of Colorado, the Murray district tungsten deposits are very promising, and will possibly rival those of Colorado and California.

Interest in the Pine Creek district continues to grow. Wallace men have taken preliminary steps for the construction of a railway from the Oregon-Washington Railroad & Navigation line at the mouth of the creek to the Constitution mine, 10 miles, and a branch up the west fork about 3 miles to tap a timber and mining area. W. H. Herrick is the leading spirit. Capital has been secured. The survey, in charge of F. Merriam, of Wallace, is half complete. Construction will commence at an early date.——The Hilarity zinc-lead mine is to be re-opened by J. M. Porter and others.——According to Judge George Turner and others of Spokane, who control the Constitution mine, an electrolytic plant of 100-tons daily capacity, to cost $425,000, may be erected at Spokane in the future. The ore averages 30% zinc, besides some lead and silver.——Aside from the Douglas mine, which is operated by the Anaconda company, the best known working properties on Pine creek are the Highland-Surprise, Constitution, Nabob, Sidney, Amy-Matchless, and Little Pittsburg. All are reached by a wagon-road from Pine Creek siding, on the O.-W. R. & N. line between Kingston and Kellogg. There are also valuable antimony mines in the district, including the Coeur d'Alene Antimony Co. The prevailing formation along Pine creek is the Pritchard series of slates, which until quite recently was regarded as unfavorable to the formation of bodies of commercial ore.

On May 1 the Tamarack & Custer Consolidated Mining Co.



MAP OF PINE CREEK DISTRICT, COEUR D'ALENE, SHOWING ITS RELATION TO WARDNER AND KELLOGG, THE LATTER WHERE THE NEW SMELTER OF THE BUNKER HILL & SULLIVAN IS BEING ERECTED.

will pay its initial dividend of 2c. per share, equal to $35,530. A 600-ton mill, to cost $150,000, is being planned.

MISSOURI

Jasper County

The ore market at Joplin last week was practically unchanged. The output of the region was 6518 tons blende, 459 tons calamine, and 1148 tons lead, averaging $97, $70, and $98 per ton, respectively. The total value was $792,307, and for 12 weeks $9,588,443.

Two men were killed and two injured in the Consumer mine at Joplin, when a slab of rock 50 ft. long, 30 ft. wide, and 2 ft. thick fell from the roof. Forty other men had a narrow escape.

MONTANA

Cascade County

Many old mines in the Neihart district of northern Montana are being re-opened. A large amount of silver ore has been extracted in the past. The Big Seven and Ripple were always worked to some extent, and produce silver-gold-lead-zinc ore. Cost of transport is high. A mill is to be erected at the Ripple to treat mine and dump ore of good value. Last September the Anaconda company leased the Queen of the Hills and Galt mines.

Work at the Great Falls zinc plant is progressing favorably. The Clifton-Applegate Co., contractors, have excavated 100,000 cu. yd. of earth in preparing the site, and the foundations of the various divisions are in the following condition at the time of writing, according to *The Anode* for March:

Roasters—concrete is being poured and the foundations will

be complete in a few days. electrolytic—forms are practically completed. lead castings—forms are practically completed, and the leaching and power-plant forms are being placed in position. As necessary adjuncts to the work there have been installed temporary buildings as follows: office, shops, boiler-house, locomotive round-house, while a warehouse is now being built. Construction tracks, piping, etc., have been placed as the work demands, these being extended and changed from time to time.

Lewis and Clark County

The manager of the East Helena smelter of the A. S. & R. Co., Frank M. Smith, states that low-grade lead ores are now in demand.

Silverbow County

With the moderation of the extreme cold weather February saw considerable progress made in construction work in all departments at the Anaconda company's Washoe works. The reconstruction of the concentrator has been completed, and the re-modeled portions are now in commission. The oil-flotation department is in full operation; No. 2 roaster is practically complete, and one-third of the furnaces are in service. The large reverberatory-furnace, which has been under construction at the converter plant for the purpose of re-treating converter slag, is also complete and in service. The construction of the last two of the Great Falls type of converter is now well under way. The addition to the zinc plant is also nearing completion and will probably be in operation during the present month. At the present time all indications point to an early completion of all construction work begun during the past year, and the output of the smelter will doubtless be greatly increased in the near future.

A few deep holes drilled in the west side of the Bullwhacker open-cut, which was crumbling away, when blasted brought down 5000 tons of 4% copper ore last week. A body of 2 to 8% ore was also exposed. Considerable underground development is under way. Monthly shipments are 3000 tons to Tacoma. Some ore will go to Garfield, Utah.

The Butte & Great Falls company is to construct an aerial tram from the mine to the Great Northern railway, over two miles.

NEVADA

Humboldt County

A rush set-in to Rye patch gold district last week, on the strength of rich ore being found, according to news from Lovelock.

Five feet of $80 ore has been opened in a winze below the 300-ft. level of the Crown Point at Rochester.——The Rochester Mines mill produced $38,800 in the past four weeks.——Promising developments are reported from the Packard Extension.

Stopes at 1500 ft. in the Seven Troughs Coalition are yielding $260 to $500 ore.

Nye County

Production of Tonopah last week was 8580 tons valued at $179,700.——The Tonopah company shipped bullion worth $57,600.——The Murray vein at 1540 ft. in the Extension is 35 ft. wide.——The West-Tonopah property is now controlled by Eastern capital, with J. G. Kirchen of the Extension as general manager. The mine, opened to 850 ft., has been closed since 1907. This transaction is of importance to the district.

NEW MEXICO

Grant County

Two 500-units of the Burro Mountain Copper Co.'s mill at Tyrone are nearing completion, and should be working early in May. All machinery is motor-driven, direct-connected. All launders and pipes are below the floors. A 3000-ton storage-bin supplies a No. 3 Symons crusher, which reduces the ore to 3-in. size. A 48-in. sorting-belt feeds three 48-in. Symons disc-crushers, which make a ¾-in. product. Allis-Chalmers rolls reduce this to 5 millimetres (¼ in.). From Cole shaking screens the over-size returns to the rolls. The fine ore is delivered to a 1000-ton bin. Feeders, belt-conveyors, weighing machine, and a roughing distributor take the ore to six Hutch art tables. Concentrate passes to vats. Tailing is reduced in Marathon mills. Following are Dorr thickeners and classifiers, hydraulic de-slimers, and sand-tables. Slime goes to Rork flotation-machines, the tailing from which passes over Senn pan-motion tables. The recovery will be over 80%, 60% being saved on the Hutchart tables. August Sandberg designed the mill assisted by C. E. Rork.

Socorro County

Higher prices for silver have added activity to the Mogollon district. The Alberta mine and Deadwood mill have resumed. The new road from Magdalena, N. Mex., will be finished in a few months. Preliminaries are complete for the highway from Greenlee county, Arizona, into the Mogollons.

OKLAHOMA

Ottawa County

It is estimated that the Commerce district will produce $5,000,000 of zinc and lead ores in 1916 ($1,000,000 being reported to the end of March), against $2,600,000 in 1915, $1,700,000 in 1914, $1,200,000 in 1913, and $638,000 in 1912.

The new and fourth mill of the Picher Lead Co. will treat 1440 tons per 24 hours. Construction is to start soon.

OREGON

Josephine County

A large deposit of iron, with indications of manganese, has been located by W. B. Sherman and others of Grants Pass, about 8 miles from the California & Oregon Coast railway, being constructed from that town to Crescent in California.

UTAH

Beaver County

On February 29 the Horn Silver Mining Co., in the San Francisco district, resumed dividends. The money for this was from the Caldo company, which bought the tailing dump for $150,000, of which $25,000 was cash. The material is being treated by flotation. During 1915 development covered 1343 ft. Lead-silver, zinc, zinc-lead, and copper ores, and old slag shipped totaled 30,057 tons, yielding $165,889. The operating profit was $18,312. The surplus is $100,449.

Juab County

At a depth of 1700 ft. in the Iron Blossom a drift will be driven 2000 ft. to connect the south or No. 1 workings with the new copper orebody in the north, 600 or 700 ft. lower than the present stopes.

The Dragon Con. is sending 80 tons of low-grade ore to the Tintic Milling Co. Some good copper-gold-silver ore is shipped. High value in gold is lately reported from the north end.

Work is being resumed at the East Tintic, North Tintic, and Zuma mines.

Salt Lake County

To haul ore from the Alta Tunnel, Cardiff, and Maxfield mines in the Big Cottonwood district to the Murray smelter the Alta Tunnel & Transportation Co. is to use caterpillar-tractors, according to the manager, Fred V. Bodfish.

When the snow has cleared away the Wasatch company at Alta will commence its 4000-ft. drainage and transport adit. This will cost $60,000. The company has just marketed another car of ore that averaged 69.60 oz. silver, 10% lead, 10% copper, and 14.70% zinc, with net value of $82.60 per ton.

Summit County

The Big Four concentrating plant at Atkinson's is to be enlarged to 750 tons per day.

WISCONSIN

LAFAYETTE COUNTY

The Benton district is shipping 50 cars zinc ore per week, and is booming. There are not enough buildings to house everybody. New producers with new plants are the Hird, Treganza, and Longhenry. Meetings have been held quietly at many points between mine operators, ore-separating companies, and agents representing a large smelting concern, for the purpose of pooling issues and building an independent zinc smelter at or near the site of the National Separating Co. at Cuba. A scarcity of drill-rigs is seen everywhere in the field. Mill-wrights are engaged on work planned a year ahead. Four miles of rock and tailing roads have been laid to connect all outlying producers with track which was finished on March 15. The Wisconsin Zinc Co. unloaded 30 cars of cypress lumber at this station during the month to be used in the early construction of two new power and milling plants, and one power plant to supply current for the company's mines and mills in this part of the field. Oil engines have been introduced by the Frontier Mining Co. for underground work. The elaborate drilling program that has been at maximum pitch for a month is daily finding rich zinc ore in virgin soil. Not a foot of land is available for leasing purposes in the two townships Benton and New Diggings, which have large bodies of ore underlying the entire districts so named. The Wisconsin Zinc Co. and Vinegar Hill company both employ 650 men, and there are 10 other companies in the district with 50 to 75 men each.

The New Diggings district, practically at a standstill at the beginning of 1915, is now the home of 1000 miners. Drills going everywhere have been rewarded with rich strikes.

CANADA

BRITISH COLUMBIA

During the current month the Britannia Mining & Smelting Co. on Howe sound will be treating 3000 tons of 3% copper ore daily. The plant is to be increased to 8000 tons capacity.

The Hudson Bay Zinc Co. is being incorporated at Spokane to operate mines near Salmo. The price of the property is $100,000, payments to be made from ore extracted. Lessees have shipped 150 carloads of 27 to 35% ore, and are now sending 50 tons daily. A 5000-ft. aerial tram is to be erected.

MEXICO

SONORA

If La Colorado Mining Co. does not resume operations at its mine 37 miles from Hermosillo P. E. Calles, governor of Sonora, will do so for them. The property is in no danger, nor would the employees be, who want work. The property will not be confiscated, but will be administered by the State, profits going to the company.

In the Department of Metallurgical Research of the State School of Mines, University of Utah, there have been established five research fellowships in metallurgy, each having an annual value of $720. These fellowships are open to college graduates who have had a good training in chemistry and metallurgy, and applications for them will be received up to May 15, 1916.

Those now holding fellowships for the fiscal year 1915-1916, and the fields in which they are working, are: Glenn A. Allen, flotation processes; Richard W. Johnson, hydrometallurgy of zinc; Harper C. Neeld, hydrometallurgy of zinc; Clarence E. Sims, electrolytic processes; M. J. Udy, hydrometallurgy of lead; Harry J. Morgan, cyanidation; and George F. Stott, losses in milling processes.

By an agreement with the U. S. Bureau of Mines, the work of the metallurgical research department is under the direction of metallurgists of the Bureau, assigned to duty at the University and Salt Lake City.

PERSONAL

W. C. WYNKOOP is at Pike, Sierra county, California.

COREY C. BRAYTON has returned from Salt Lake City.

BEN. S. REVETT has returned to San Francisco from New York.

HEATH STEELE has taken an office at 60 Broadway, New York.

SCOTT TURNER sails from New York for Lima, Peru, on April 8.

W. W. BREEN of Sonora, California, was in San Francisco last week.

JOHN ALLINGHAM, of Oakland, is at Virginia City for Charles Butters & Company.

FREDERICK E. BURBIDGE, of Spokane, has been made general manager for the Federal Mining & Smelting Co. in Idaho.

CHARLES O'CONNELL, manager for the Tough-Oakes gold mine, is returning to Kirkland Lake, Ontario, after a holiday in California.

A. W. STICKNEY, consulting geologist for the Kyshtim Corporation, Russia, is in New York. He will visit Boston and then sail for Russia.

ELTON W. WALKER has returned from Boston to Houghton, and has been made general manager of the Adventure mine, which will be re-opened shortly.

ICHIRO KAMIMURA and HARUYOSHI TOMITA, engineers to the Osaruzawa mine of the Mitsubishi Company, in Japan, are making a journey of observation to our western mines and smelters.

W. A. WASLEY is now mill superintendent for the Lucky Tiger Mining Co. and W. H. FOESTER is cyanide superintendent. W. R. MAYCUMBER, former mill superintendent, has accepted a position with the Chile Copper Company.

H. STONE, of the Murex Co., Ltd., has closed his laboratory in San Francisco and has moved it to Darwin, Inyo county, California, where a mill is being erected to treat lead carbonate. For the next few months tests are to be made at this plant.

Schools and Societies

MACKAY SCHOOL OF MINES, Reno, students are visiting Rochester, Tonopah, and Goldfield in Nevada, and Grass Valley, California.

The UNIVERSITY OF CALIFORNIA summer session begins on June 26 and closes on August 5. No formal examinations are required for entrance; admission is granted to all persons of sufficient maturity and intelligence to profit by the exercises of the session. The tuition is $15, regardless of the number of courses taken, the usual ones being offered.

The Southern California section of the A. I. M. E. met at Los Angeles on April 4. A feature of the meeting was the reading of a group of valuable papers on 'Mining Conditions in South America.' The leading paper dealt with the structural features and mineral districts of the continent, by Bailey Willis, professor of geology at Stanford University.

The AMERICAN ASSOCIATION OF ENGINEERS announces that it has signed a five-year lease for suite 601-604 at 29 south LaSalle St., Chicago, Illinois. This is the second time in 9 months that the new society has been compelled to enlarge its quarters. It has now a membership of 500, sixty-five per cent of which is in and near Chicago, and the remainder is scattered throughout the United States, Canada, England, Philippine Islands, and even in South America.

THE METAL MARKET

METAL PRICES

San Francisco, April 4

Antimony, cents per pound	44
Electrolytic copper, cents per pound	29
Pig lead, cents per pound	$8.00—8.80
Platinum, soft metal, per ounce	$88
Platinum, hard metal, 10% iridium, per ounce	$92
Quicksilver, per flask of 75 lb	$200
Spelter, cents per pound	22
Tin, cents per pound	46
Zinc-dust, cents per pound	30

ORE PRICES

San Francisco, April 4.

Antimony, 50% product, per unit, of 1%, or 20 lb	$2.25
Chromic, 40% and over, f.o.b. cars California, per ton	12.00
Magnesite, crude, per ton, f.o.b.	8.00
Magnesite, plastic, no iron and lime, calcined, ton	25.00—30.00
Magnesite, refractory, 11% iron, dead-burned, ton	35.00
Manganese, 50% metal, 8% silica, per ton	12.00
Tungsten, 60% WO_3, per unit of 20 lb	70.00—80.00

Tungsten prices at Boulder, Colorado, remain around $95 per unit, $15 higher than in New York, and a drop to $75 is predicted by some acquainted with the market.

New York, March 29.

Fair-sized quantities of antimony ore have been purchased at around $2.50 per unit for forward shipment. The demand continues.

Up to $78 per unit has been paid for forward shipments of tungsten. For prompt delivery $90 is said to have been given.

From 70 to 80c. per unit is quoted for manganese. The U. S. Manganese Corporation will soon produce ore from its mine at Elkton, Virginia. The Crimora Manganese Corporation will have a new plant completed at its manganese mine at Crimora, Virginia, in April. Both concerns have plenty of ore.

EASTERN METAL MARKET

(By wire from New York.)

April 4.—Copper is firm, with futures active; lead is quiet but firm, near futures in spelter are active.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending

A steady and strong rise characterizes the silver market, backed by demands from England, Europe, and India.

On March 28 the 'Tenyo Maru' took $525,000 (875,000 oz.) of silver to the Orient. The movement of Allied troops, especially from India, results in a large demand for small coins (silver), and transfers considerable quantities from one country to another.

June	30.72	40.26	....	Dec.	33.60	38.71	....

Tin is strong at 50 to 52 cents.

Antimony continues strong in New York at 45 to 46c., duty paid for Chinese and Japanese grades. Canadian interests have contracted for 500 tons delivered during the remainder of the year.

Eastern Metal Market

New York, March 29.

Lead continues to present the prominent feature of the market. The price to domestic consumers is about 8c., New York and St. Louis; but this is the quotation of independent producers, and not that of the A. S. & R. Co. The latter disapproves of the present high speculative level of prices, regarding it as unfair to American consumers, regardless of what the nations at war may pay. It is selling on the average of its quoted prices, not on the daily price quoted. For export, sellers have refused a price equal to 8.50c., St. Louis. Again, 8.25c., Chicago, has been done. Copper is firmly held awaiting a renewal of foreign buying, following which domestic consumers are expected to become active. Zinc has been dull and is easier, and, in view of the many offerings, the trade is beginning to wonder if production has been overdone. Ample tin arrivals have eliminated fear of a shortage, but the price stands at 50c. Antimony was strengthened by some good Canadian buying. Aluminum is practically unchanged.

In steel the crest of the high prices appears to have been reached, although it is dangerous to predict these days. Foundry pig-iron, which has been lagging as compared with steel, is showing more activity and prices are stronger. Steel forging-billets are stronger, while the other products show but little change. Pittsburg quotations are 2.75c. for steel bars, 3.50c. for plates, and 2.50c. for shapes. Eastern Pennsylvania makers exact premiums over these prices. Two enterprises for the mining of manganese ore in Virginia, and its manufacture into ferro-manganese for steel-making, have been organized.

COPPER

The market is quiet, but firm, awaiting a renewal of demand from abroad which, when it comes, is expected to stir domestic consumers to activity again. Trading continues to be, so far as there is any, in forward positions. June and July electrolytic is quoted at 26.75 to 26.87c., the lower price being quoted by second-hands and for limited quantities. Immediate shipment is quoted at 28.50c., but a firm offer of 28c. would not be turned down. April and May can be done at 27.25 to 27.50c., and June and July at 27c., 30 days, delivered, equal to 28.87c., New York, and, as already said, this price might be shaded. On one or two days there has been moderate buying, but on the whole the market has been quiet almost to dullness. The freight embargo against New England metal users has been raised occasionally, and this has permitted them to get deliveries of much needed supplies, but their stocks are still low and their situation uncertain. Last week it was reported that the French government was in the market for 2000 to 4000 tons, and yesterday a report was current that the same country was inquiring for 10,000 tons, but no one seemed to know the source of the alleged inquiries, and there is a strong suspicion that these reports were given circulation to bull a slow market. It is usually so with reports that first appear on the financial news ticker and in Wall Street papers. Of course, France is expected to buy in the near future. Lake is entirely nominal at 27.12c., June and July delivery. The London quotation for electrolytic is unchanged at £136. Exports to the 28th totaled 20,873 tons.

ZINC

In the past week this metal has been almost continuously dull, and some evidence of pessimism is discerned in the selling trade. The quotation yesterday was about 17.75c., New York, equal to 17.50c., St. Louis, for prompt shipment, while April could be had at about 17.25c., St. Louis, and May at 16.50c., St. Louis. The trade is wondering if the production of spelter is not being overdone, a thought which has its inception in the large number of offerings which are being made. Persons and firms never before heard of in the metal field are said to have spelter to sell, and there can be no question but that production has been crowded to its utmost. Again it is pointed out that the demand from abroad may be lessened in view of a move of the British government to help along production in England. The plan is to subsidize companies which smelt Australian ores. At the same time, the metal so produced will not be available for months to come. Exports from the 1st to 28th, inclusive, were 1405 tons. The London quotation for spot zinc was £95 on the 28th. Sheet-zinc is unchanged at 25c., carload lots, f.o.b. mill, 8% off for cash.

LEAD

The situation continues a most interesting one. Though domestic consumers have paid from 8 to 8.25c., the first-named price is nearer the actual market. Japan and Russia continue anxious to get lead by way of Pacific shipment, but many of the producers profess themselves unwilling to take the business at any price. In fact it is protested on several sides that the domestic consumer must be cared for. The A. S. & R. Co. continues to quote 7c., New York, but this is a nominal figure. Where it is making sales the stipulation is made that monthly averages of its own quotations must govern. The company's method of quoting, or rather not quoting, aroused so much comment that an explanatory statement was issued by Edward Brush, vice-president. He stated that the A. S. & R. Co. desires to do business in a stable manner and not along speculative or temporary lines; that more than 75% of the company's production of lead is sold on average-price contracts; that it prefers to give preference to its regular customers, and that: "If the price of pig lead continues to advance, it will result in decreasing consumption and curtailing the lead industries of the United States. It is not the opinion of this company that this would be advisable, even if the extraordinary demands of other parts of the world are such as to warrant their paying prices for war material that are not warranted by domestic consumption." Earlier in the statement appears the following: "Aside from the amount of lead produced by our own mines, all of the lead that we produce is received from mines with which we have contracts requiring the miner to ship his entire production to our company, and for which the miner is paid daily in accordance with our quoted price. Therefore, the lead that we receive in any month is paid for by us to the miner at our average quoted price for the month." Other interests have shown themselves averse to selling for export. Last week an offer equal to 8.50c., St. Louis, for export by way of the Pacific Coast was declined. At the same time 8.25c., Chicago, was paid, and for the first time in the memory of the trade, lead was shipped west from New York. This week the market has quieted down, and it is hoped that more normal conditions are near. Odd lots in the hands of those who desire to realize profits are coming out. The London quotation on March 28 for spot was £34 15s. Exports to the 28th totaled 4001 tons.

TIN

Fears of a shortage of tin this month have been dissipated by the rather large arrivals of the month, which up to the 28th totaled 3803 tons. There was afloat on that day 4825 tons. The market has been dull for days, except for one or two flurries of fair inquiry for April delivery. The New York quotation for spot yesterday was 50c. The Welsh tin-plate manufacturers are taking little tin, and this may have released some of the recent arrivals. The American tin-plate producers are consuming at a heavy rate.

COMPANY REPORTS

SOUTH EUREKA MINING CO.

The result of operations during the year ended February 29, 1916, has been supplied us by the secretary and treasurer, Edward Fox, as follows

Ore treated, tons	115,124
Recovered value of ore	$3.964
Average yearly tailing loss	0.375
Average yearly value of ore milled	4.339
Average yearly value of concentrate	68.990
Average yearly cost per ton milled	3.087
Gross bullion production	$411,633
Gross concentrate production	163,698
Earnings from investments	1,730
Earnings from rentals, supplies, etc.	2,993
Balance paid out in excess of receipts	2,708
	$582,762
Operating expense	$448,013
Construction and equipment	8,825
Dividends paid (38c. per share)	125,354
Material and supplies	570
	$582,762

This company operates at Sutter Creek, Amador county. It has a deep incline shaft and good 80-stamp mill and concentrating plant.

PHELPS, DODGE & CO.

Copper Queen Consolidated Mining Co., Detroit Copper Mining Co., Moctezuma Copper Co., Burro Mountain Copper Co., Bunker Hill Mines Co., Stag Cañon Fuel Co., Phelps-Dodge Mercantile Company.

With an issued capital of $45,000,000 Phelps, Dodge & Co. controls the above operating companies in Arizona, Mexico, and New Mexico. The report covers 57 pages. The president, James Douglas, states that the records of the company for 1915 embody some interesting vicissitudes besides those of its statistics.

The total production of the firm's copper companies amounted to 140,478,003 lb. As there was no copper treated for outside concerns on toll this shows an increase of 8,815,679 lb. from company and custom ores over the output for the previous year. This large output was secured although the production, which had been lowered in 1914 by reason of the stagnation of the markets, was still curtailed for two months of 1915, and was further affected by the strike which closed down the Detroit mines in September until after the close of the year. The Mexican troubles also repeatedly paralyzed railroad transportation between Nacozari and Douglas, and compelled a shut-down of the Nacozari plant for 135 days.

Including copper received from outside sources, 194,925,668 lb. was sold and delivered to buyers at an average price of 16.079c. per pound, net cash, f.o.b. New York.

Of the total quantity of copper sold and delivered during 1915, there was sold almost equal quantities to the domestic and foreign trade.

The market during the year followed an extraordinary course. When prices advanced, to derive the utmost benefit from the improved market, the blast-furnaces at Douglas were driven to their utmost speed, and the new reverberatory-furnaces smelted daily from 600 to 700 tons of ore. A large reserve of ore had accumulated at the smelter, which was freely drawn upon.

The policy of the company in Mexico has been to employ as few Americans as possible, and to educate Mexicans to take the place of Americans when the latter could be dispensed with. The experiment was skillfully worked out when James S. Douglas was superintendent, and has been followed by J. S. Williams, who succeeded him, and his aides. It seems quite possible to raise a native community to a commendable standard of living, and to educate a selected number in modern methods of work.

The year passed without any friction at the Stag Cañon coal mines, despite the proximity of the Colorado mines, which were the scene of so much disorder.

The Iturro Mountain mines have been put in condition to produce ore, and the mill should start up within a month (March or April).

It is too soon as yet to predict the fate of Tombstone, but initial work leads the management to believe that profits will come from several other metals besides gold and silver.

During 1915 Phelps, Dodge & Co. results were as under:

Earnings	$10,981,512
Less ore depletion and plant depreciation	1,261,037
Net	$ 9,720,475
Balance from 1914	7,617,389
Total available	$17,337,861
Dividends paid (4)	9,000,000
Balance for 1916	$ 8,337,861

Metals on hand and in process are valued at $14,552,370.

Four dividends of 2½% each, an extra dividend of 1% in March, and extra dividends of 3% each in June, September, and December, in all aggregating 20%, were paid during 1915, amounting in all to $9,000,000.

The general manager, Walter Douglas, stated that the copper ore extracted from all mines amounted to 1,583,364 tons, of which 800,600 tons was submitted to preliminary concentration and 782,764 tons was smelted direct. The total amount of copper-bearing material smelted, including ore, concentrates, old slag, and cement copper, was 1,129,766 tons. The copper bullion contained 29,840 oz. gold and 1,388,149 silver.

In addition, there were produced and sold 30,442 tons of lead ore and concentrates from the Copper Queen and Bunker Hill mines, yielding 892,000 lb. copper, 9,525,584 lb. lead, 267,520 oz. silver, and 1856 oz. gold.

Of the ore and concentrates smelted, 1,016,746 tons was derived from the company's properties, and 113,020 tons was purchased.

At the mines of the Copper Queen, continued and systematic development by churn-drilling has extended the previously discovered bodies of disseminated ores so considerably as to assure many years' supply for a large concentrator. The copper-content of this ore is above the average of similar deposits now being profitably exploited, and the percentage of recovery, as demonstrated by the experimental mill operated throughout the year, is quite satisfactory. Ore reserves in the Limestone division of the mines remain approximately the same as at the commencement of the year.

At the Burro Mountain mines, development, confined almost exclusively to preparing the known orebodies for extraction, has in some cases materially extended the areas of these deposits. Churn-drilling has also served to discover other ore occurrences which may be of great importance when systematically defined and explored. The property of the Savanna Copper Co., comprising about 2234 acres and adjoining that of the Burro Mountain company, was purchased. Exploratory drifts are being driven from the Niagara adit and No. 3 shaft to prospect a deposit the existence of which was discovered by the Savanna company some years ago.

Operations on the upper levels of the Bunker Hill Mines Company have not as yet developed orebodies of great size or commercial importance. The low-grade material which has been opened in the mines has been thoroughly tested by both cyaniding and concentrating, with inconclusive results. A

profitable market now exists for the manganese ores which occur so generally through some sections of the property, and advantage will be taken of the present high price for this mineral to ship heavily of both ore and concentrate.

In the Phelps Dodge Mercantile Co. the total sales and the net profits slightly exceeded those of 1914.

The superintendent of the Copper Queen mine, Gerald Sherman, reported that exploration and development amounted to 68,432 ft. in the Limestone mine, and 3207 ft. in Sacramento hill (also 42,953 ft. of churn-drilling), in addition to 9924 ft. of special work, and 3772 ft. for development of lead ore. No new orebodies were found, but reserves were kept at the maximum quantity. These were 2,696,940 tons in the Limestone, and 11,633,481 tons of 2.455% copper ore in the Sacramento. There was mined 722,344 tons of 6% ore, 65.9% of the quantity by the square-set method. Direction of scientific underground work is in charge of the geologist, Arthur Notman.

Forest Rutherford, in charge of the reduction-works at Douglas, stated that 7.79 blast-furnaces treated 1,012,669 tons, 1.68 reverberatories 207,677 tons, and 5.3 converters 34,237 tons of various materials; 11.4 roasters also operated. Metal production was 125,144,027 lb. copper, 1,388,149 oz. silver, and 28,840 oz. gold. The laboratory made 111,268 determinations. Little new construction was done. The irregular shipments of ore and concentrate from Nacozari rather interfered with smooth operation.

The general manager, S. W. French, reviewed the Copper Queen's results generally. There was an average of 1883 men at the mines, 965 at the works, and 18 in the hospital department; a total of 2866, against 3178 in 1914. Wages were advanced in May, on the basis of the price of copper. Injured employees received a total of $41,027, less than half of that in 1914, due to safety precautions. Nine men were pensioned, making 25 in all under this scheme. The employees' benefit association's income was $62,977, the company contributing $12,500. The year left a surplus of $16,465, against $5700. An average of 76.3% of all employees are members. In the hospital department, Dr. F. E. Shine reported a deficit of $6456 on an income of $81,357. A great number of calls, examinations, operations, etc., were recorded.

At the Detroit property, the mine superintendent, Frank W. McLean, reported that development advanced 14,709 ft. Working conditions were good, but the orebodies are decreasing in size. There was one fatal accident. There was extracted 372,710 tons of 2.8296% ore, of which 361,970 tons averaged 2.694%, suitable for milling.

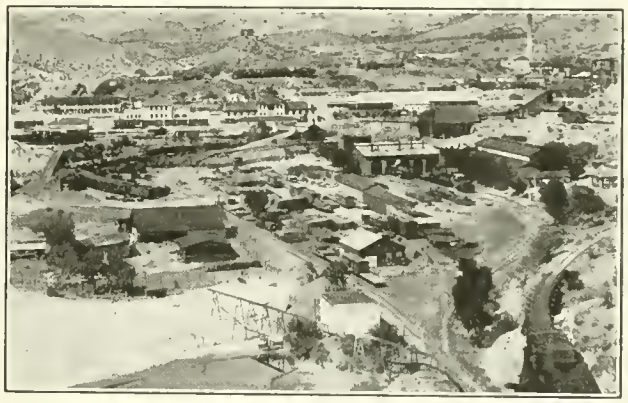
V. P. Hastings, in charge of the smelter at Morenci, stated that the plant reduced 110,286 tons of ore concentrate, flux, etc., yielding 15,333,976 lb. copper.

Development, treatment, and general were discussed by the general manager, M. H. McLean. In the producing area of the mine, results were very encouraging. The mill saved 73.92%. A flotation unit is now at work. There were 1307 men employed. Production was suspended in September 11, due to the Western Federation of Miners' strike, now a matter of history.

Affairs of the Moctezuma Copper Co., at Nacozari, Sonora, Mexico, are described by J. S. Williams, Jr., the general manager. Owing to the revolution in Mexico the mill operated only 135 days. During the greater part of 1915 there was no train service between Nacozari and Douglas, so that it became necessary at three different times to pile concentrate on the ground. This and the subsequent loading of same into cars, was expensive and materially increased milling costs. There was treated 424,027 tons, assaying 3.412% copper, yielding 90,014 tons of 13.316% concentrate, with 83.6% recovery. In actual running time there was 1847.1 tons treated daily. Numerous tests were made with flotation, and a 600-ton plant is to be erected in 1916. The Copper Queen smelter produced 23,990,286 lb. of copper, 599 oz. gold, and 331,836 oz. silver from the concentrate, etc.

Development at the mine amounted to 7572 ft. Ore reserves to a depth of 1200 ft. are estimated at 2,912,830 tons net in place, and 307,142 tons broken in stopes, a decrease of over 250,000 tons. Greater depth is necessary to maintain reserves. The Pilares, 1285 ft., and Esperanza shafts are to be equipped with electric hoists of 2500-ft. capacity, also a steel head-frame at the latter.

Activities of the Burro Mountain Copper Co. in 1915 were directed mainly toward the completion of construction work at the mine and the concentrator, preparatory to entering the field of active production in the early months of 1916, according to the superintendent, E. M. Sawyer. Churn-drilling resulted in 20 holes being put down an average depth of 1030 ft. each, by three machines. The extent of the ore deposit was further proved. The experimental plant has treated 11,009 tons of ore, giving a scheme for the new 1000-ton mill. A



NACOZARI, SONORA, MEXICO.

total of 16,976 tons of ore, etc., was produced containing 1,354,377 lb. of copper. The hospital cared for a good many complaints. A town-site was decided on, and B. G. Goodhue, of New York, has planned the town. The central group of buildings will include a club-house, theatre, hotel, bank, depot, and post-office, as well as the company's general office and the Phelps Dodge Mercantile Co.'s store and warehouse. Sites have been chosen in the neighborhood for churches, and a school-house with ample capacity for present needs. Dwellings are being erected for employees.

The mine superintendent, E. F. Pelton, reports that ore reserves are 2,555,000 tons averaging 2.53% copper. Development last year cost $5.352 per foot. Duplicate steel headframes and hoists were installed at No. 2 and 3 shafts. There were 385 employees at the close of the year.

Re-opening the old Tombstone properties by the Bunker Hill Mines Co. has attracted much attention, and in the report of E. Grebe, the superintendent, are some interesting data. Development advanced 5049 ft. Results from prospecting in old workings and in virgin ground give promise of a considerable quantity of ore, generally low grade, above water-level. Marked improvements were made in the equipment for ore transport from mines to mill. Production was 10,746 tons of ore, containing 1373 oz. gold, 109,784 oz. silver, 269,303 lb. lead, 23,760 lb. copper, and 1,171,599 lb. manganese. The experimental cyanide test-plant treated 5788 tons of ore, with a recovery of 79.9% gold, 84.5% silver, and 35.6% lead. There were 297 men employed.

The general manager of the Stag Cañon Fuel Co., at Dawson, New Mexico, T. H. O'Brien, reports that 1,265,674 tons of coal was extracted. From 531,488 tons of washed coal was made 265,753 tons of coke. There were 9 fatal accidents. A good many improvements were made.

W. H. Brophy reports that the Phelps Dodge Mercantile Co.'s gross sales were $6,210,457, an increase of $290,234. The net profit was 8.54%. At all the stores were 480 employees.

BOOK REVIEWS

'The Flotation Process.' Compiled and edited by T. A. Rickard. P. 361. Ill., index. For sale by the Mining and Scientific Press. Price, $2.

The subject of flotation unfortunately has been violently agitated in the courts. Judgment has been suspended pending the separation of the contaminating influence of acid, and even caustic, remarks, from a clarified conception of the prior art. Much frothy argument has resulted, and hindered the experimentation on other ores and the probable general application of the process. From this mixture of patents, principles and processes, Mr. T. A. Rickard has extracted and presented to the mining fraternity, in concentrated form a clear and comprehensive review of the present status of this important subject. All engineers will welcome the publication of this competent, unprejudiced, suggestive, and helpful book on flotation. The application of the physics of liquids and gases to the separation of metals from non-metallic substances promises to revolutionize metallurgical industry and convert much of our present discarded waste into commercial material. Knowledge of the subject is still elementary, the basic principles are but imperfectly understood, and it is only by generous and competent discussion that progress will be made.

'The Flotation Process' is an edited compilation of a series of articles by many engineers, giving the results, both successes and failures, of their work. It is therefore suggestive. Careful reading will obviate the duplication of failures and initiate further experimentation. The book is of practical value in that the reader is spared other than pointed reference to the early history of the use of oils to mineral separation. Several installations of different types are intelligently described and clearly illustrated. Conflicting ideas and interpretations of the principles involved necessarily exist and are presented in such form that they enlighten the reader. The researches and opinions of such men as Callow, Ralston, Durell, Bains, and others always carry weight, and the discriminating student will separate the concentrate from the froth even in books.

The lack of bias adds to the force and value of the book. Credit is given where credit is due, to all litigants and operators. The book is refreshingly free from party feeling, such as has characterized other writings on this subject.

This handy volume is not a text-book. It makes no claim to finality, but it is a timely contribution to metallurgical literature. It will supply superintendents with up-to-date information on the theory and practice of flotation, therefore serving a useful purpose to the mining profession.—F. H. P.

The Diesel Engine in Practice. By J. E. Megson and H. S. Jones. P. 136. Ill., index. Technical Publishing Co, San Francisco, 1916. For sale by Mining and Scientific Press. Price, $2.

This is the second book on the Diesel engine that we have reviewed during recent months, and although there is an interesting lot of information included, it is not worth the price, other things being equal, with the other work. The subject is brought home to California engineers by notes and photographs (not very clear) of two makes of Diesels at the Exposition last year, and mention of the ship *Siam*, which called here. The first chapter gives a brief history of the engine. This is followed by operation of the two and four-cycle machine, with efficiencies, heat balance, etc. Experience with earlier installations is of interest. As fuel-oil is the source of power in the Diesel, a chapter is devoted to it. The effect of altitude is next discussed, as such engines do not develop as much power as at sea-level. Practical directions cover the operation and care of the Diesel, and its life and reliability. The commercial situation and use in ships concludes the work.

MINING DECISIONS

Deposit on Mineral Lease—When Recoverable

Where plaintiff had made a deposit to secure from defendants a coal-mining lease on certain stipulated terms, and defendant thereafter insisted on adding other conditions to which plaintiffs would not agree, and no lease was as a matter of fact ever executed, plaintiffs were entitled to recover their deposit.

Raccoon Coal Co. *v.* Faulkner (Kentucky), 181 Southwestern, 1106. February 2, 1916.

Oil-Lease—Form Not a Pre-requisite

An agreement between the holder of land under a contract-of-purchase and a second party, providing that the latter shall take possession of the land and develop oil thereon, rendering to the other a portion of the product in payment of its use, is a lease, irrespective of its form or the designation given it by the parties.

Comins *v.* Guaranty Oil Co. (California), 154 Pacific, 882. February 5, 1916.

Acquiescence in Oil-Well Drilling—Effect

Where a land-owner in writing agreed to execute an oil-lease on certain land, and thereafter permitted the proposed lessees and their successors in interest to operate under the terms agreed upon for 25 years, although a lease was not as a fact ever executed, a court of equity will not grant an injunction to restrain further drilling in the area contemplated by the original negotiations, but will deem the acts to have been performed in accordance with some agreement.

De Hart *v.* Enright (New York), 157 New York Supplement, 46. January 1916.

Utah Land Grants—"Known Minerals"

The Circuit Court of Appeals (Eighth Circuit) has recently decided two important cases affecting coal lands in Utah. In the first cases cited below it was held that the grants by Congress to the State of Utah of specific lands for school purposes under the Enabling Act for that State carried all mineral titles with it as well as non-mineral titles. In the second case it was held that a "floating grant" made to the same State under the Act of July 16, 1894, did *not* pass title to lands known to be coal-bearing at the date of their selection, and that the claimants of said lands had defrauded the United States in alleging their character as non-mineral. The rule of the Burke case was invoked to the effect that the action of the Secretary of the Interior is not final where it is based upon *ex parte* fraudulent and false statements of claimants.

Sweet *v.* United States, 228 Federal, 421.

Milner *v.* United States, 228 Federal, 431.

Coal Lease—Effect of Failure of Mineral

A mining lease provided that it should continue for 15 years unless the mineable coal in the land should be sooner exhausted, that the lessee should pay a fixed royalty and, in case the royalties did not reach a minimum sum, should pay that sum per annum, and that the lessee should have the right to abandon the lease at any time on account of the thinness of the coal. The lessee opened a shaft and proceeded to extract some coal, but it soon petered out. Thereafter he used the shaft, in accordance with permission granted in the lease, to remove coal mined under adjoining land. Held, that the lessee was liable only for royalties on the coal mined from beneath the lessor's and not from the adjoining land, although the lease was not formally forfeited for some time after the first deposit was exhausted. A mining lease pre-supposes the existence of mineral, and is conditioned upon its existence.

Vandalia Coal Co. *v.* Underwood (Indiana), 111 Northeastern, 329. February 2, 1915.

EDITORIAL

T. A. RICKARD, Editor

THIS was a war to end war; now there is much talk of the war after the war, that is, of a trade conflict between the two groups of belligerents, in which tariffs are to replace trenches and economic weapons are to be used as ruthlessly as hand-grenades. Only a confirmed optimist can foresee an abatement of the hatreds and prejudices of today.

PATENTS are again discussed in this issue, and in a most informing manner, by Mr. James M. Hyde, who will be recognized as the defendant in one of the most important litigations now pending over flotation patents. Mr. Hyde is able to see both sides of the problem, for he has been both a patentee and an alleged infringer of patents.

LETTERS under 'Discussion' this week include a timely notification by Mr. E. M. Hamilton, known to our readers as an experienced metallurgist, that cinnabar ores can be treated by flotation. Another metallurgical friend, Mr. F. H. Mason, contributes the very information we wanted concerning the treatment of antimonial gold ore in Nova Scotia. The third letter is a reply to our recent criticism of the State Insurance Commission. We are pleased to give Mr. Will J. French an opportunity to reply; and it must be granted that he makes a good defence.

WHAT the rise in spelter has done for mining is indicated by the annual report of the American Zinc, Lead & Smelting Co., which made an operating profit of $5,293,878 in 1915 as compared with $77,692 in 1914. In the last quarter of last year the profit was $2,344,072 as against only $320,251 in the first quarter. A working capital of $3,668,707 is retained, in consequence of the great increase in the value of ore carried. The carrying of stocks of metal and ore is today increasingly burdensome to the big smelting companies by reason of the higher price of the products and the uncertain market.

NEXT Tuesday is the tenth anniversary of the earthquake and fire that proved so annoying to us and to many others in the year 1906. That catastrophe was a pin-prick compared with the calamity now shaking and burning Europe. Turning to matters less portentous, we recall that ten years ago at this time our contemporary at New York celebrated its fortieth anniversary, whereupon we made a kind reference to our "junior" on Manhattan island. This was followed by the destruction of our plant and library, so that since then we have been most careful in anything we have said about that same useful periodical. We congratulate the *Engineering & Mining Journal* on its semi-centenary and wish it continued life and prosperity.

NAMES are easier given than withdrawn. In naming orebodies and shafts it is well to avoid points of the compass and similar terms. The 'north' shaft may fit until another is sunk farther north and a 'middle' oreshoot may be descriptive at one stage of development only. We recommend the naming of the principal workings and orebodies after the engineers and directors of a company. It is a compliment and a convenience.

WHEN the punitive expedition crossed the border in pursuit of Villa, it was announced by the President that the troops would be withdrawn as soon as their purpose was accomplished, but no provision has been, or can be, made for contingencies arising from a failure to capture Villa. On that now hinges the next chapter of the Mexican melodrama. Villa is drawing the American troops farther and farther from their base, Carranza refuses to sanction the use of the railways for military purposes, a long line of communication has to be maintained and guarded, that line is subject to attack from bands of brigands or patriots—the distinction is unimportant—and such attack would lead to reprisals. In short, the Mexican question is still sitting on a powder magazine smoking an explosive cigar.

ONTARIO soon will be producing more gold than silver. In 1915 the silver output, mostly from the Cobalt district, was worth $12,200,000; in the same period gold was produced, chiefly from Porcupine, to the value of $8,386,956. The Hollinger is now one of the great gold mines of the continent; last year it yielded $3,000,000, of which $1,560,000 was paid in dividends, which represents 52% on the capital of the company. The Dome has improved in a gratifying manner, so that a largely increased production is assured. In the Kirkland Lake district, which was wildly boosted three years ago, the real work of development has been rewarded, so that, among others, the Tough-Oakes mine has become a sound enterprise. Altogether this province of Canada is proving itself a splendid mining region, for to the precious metals must be added nickel mining at Sudbury, responsible for an annual output of $10,000,000 in nickel and copper.

LACK of shipping is going to prove an increasing check to international trade, for the use of vessels for transporting military men and materials, more than the actual destruction of shipping, has diverted a great

many ocean freighters from the trade routes. Rates to British ports are now ten times what they were before the War, and our Department of Commerce has figures showing that ships have carried in one over-sea voyage more than their hull value in 1914. Since then the increment has been 500 to 600%. Lloyd's list gives 2193 ships, representing 3,774,319 tons, as detained, captured, or destroyed by belligerents up to January 22. Fully 4,000,000 tons of shipping has been requisitioned by the Allies, while 5,000,000 tons of Austro-German shipping is held at home ports. In short, one half of the total world's tonnage is no longer available for the purposes of normal trade.

OUR contemporary *Practical Engineer* brings forward a suggestion for a new system of measurement. The decimal system is based on the digital counting of human childhood, while the metre represents a division of a quadrant of the earth's surface, just as the yard was the measure of human reach. Both of these are arbitrary units; one is represented by a metal bar in Paris and the other by a metal bar in London. Neither has a scientific basis. Therefore our contemporary offers 5 feet or 60 inches as a convenient unit. It is equal to 1.524 metres, or 152.4 centimetres, and is divisible by 2, 3, and 4, while the length in inches is divisible by 2, 3, 4, 5, and 10. It is suggested that this new unit or *nu* should be adopted by the Pan-American countries, the subdivisions to be selected by a scientific committee chosen by the Pan-American Union. We submit the idea to our readers as something worthy of their consideration.

WE publish a timely article on the geology of the Cottonwoods, that is, the Big and Little Cottonwood districts, in Utah, by Mr. L. O. Howard, our regular correspondent at Salt Lake City. How much such information is in demand by mining operators is indicated by the petition being prepared for transmission to Washington asking that the Geological Survey render available forthwith all the information collected concerning this interesting mining region. The relative importance of the subject can be inferred from the fact that during 1915 there were 55 companies at work in the two districts, producing 27,309 tons of ore, valued at $605,336, and employing 519 miners. These figures are not particularly imposing, for the operations are mostly on a small scale on young and promising mines. So far the speculative interest excited by the work in progress has been disproportionately big, for out of 16,867,514 shares traded on the Salt Lake Stock Exchange, no less than 6,707,481 represented properties in the Cottonwood and American Fork districts. Evidently there is public interest in this part of Utah, and that justifies the request for scientific information from the Survey. It will be noted that Mr. Howard expresses a poor opinion of the reconnaissance survey, made by Messrs. Butler and Loughlin in 1912, and published in Bulletin 620-I of the Survey. This work was done hastily, and without much good fortune, but it seems to us that the people of any mining district should not be too severely critical of such tentative work, otherwise the Survey will be justified in withholding such preliminary information for belated confirmation. However, a little criticism will do no harm; it will lessen the self-complacency of the official geologist, and stimulate the Survey to better effort.

MERCURIAL is a word to describe the market for quicksilver. It goes up and down with slight changes in the temperature of speculation. After reaching the extraordinary price of $300 per flask, it has dropped to $160 and dealings have become a matter of private negotiation. The market is in the hands of a few and for that reason has been anything but representative, as explained at length in our issue of April 10, 1915. Lately the demand for mercury to make fulminate or mine-contacts, anaesthetics or lighthouse mirrors, things maleficent or beneficent, as the case may be, has abated. The market is sensitive. A ship arrives at New York with 400 flasks and dealers are intimidated. The mines of New Almaden are said to threaten a sudden supply—several thousand flasks—from the dismantling of old furnaces, and so forth. But the clean-up of dumps and remnants of various sorts has been in progress for two years at New Almaden, so that the threat may be discounted. The shipment from Italy was sent to the Du Pont works, at Wilmington, to be manufactured into fulminate and then to be returned to Italy, just as another consignment from England was sent across the Atlantic, to the same manufacturer, also to be returned as an explosive. Speculators have been scared, but those who are mining cinnabar need not fear the lack of a good market so long as the War lasts.

RAINFALL at Globe, Arizona, is only 17 inches per annum, most of it coming in the months of July and August. This district is typical of the arid mountainous region in the South-west. Yet the Old Dominion mine at Globe is one of the wettest mines in the country. During the first half of last year, the pumps handled 1,624,740,000 gallons of water, while in March alone over 407,000,000 gallons was pumped, an average for that month of 13,000,000 gallons per day or 9000 gallons per minute. As our readers are aware, the amount of water that it is necessary to pump from a mine bears little relation to the rainfall or seasonal precipitation at surface. In some of the Lake Superior copper mines, for instance, in a region of plentiful rain and snow, the workings are unpleasantly dusty from lack of moisture in the lodes. In the long submarine slopes of the Nova Scotia Steel & Coal Company's iron mine, at Wabana, Newfoundland, only an insignificant amount of water is detectable, despite the weight of the Atlantic Ocean overhead. As is suggested by Mr. P. G. Beckett, the general manager for the Old Dominion Copper Mining & Smelting Company, in a paper prepared for the Arizona meeting of the American Institute of Mining Engineers, the topography and structural geology of a district play an important part in determining the flow of

water in a mine. At the Old Dominion, the Madera diorite, penetrated by one shaft and capping the main workings, resembles a decomposed granite in crumbliness, being "intensely porous." The dacite flow underlying this rock is not, at first sight, particularly porous, "but once fractures in the dacite allow the downward seepage of water from the diorite above, the formation loses all pretense of firmness, absorbs water like a sponge, and becomes sandy, crumbly, and difficult to hold." It is interesting to note that the Calumet & Arizona Mining Company at Bisbee, where similar arid conditions obtain, ordinarily pumps over 1,500,000,000 gallons of water per annum from its Junction shaft. We have known of companies planning shaft-sinking equipment which provided plentiful pumps and boilers to handle the immense amount of water that was anticipated, only to be pleasantly surprised by finding almost none. The reverse case, where shafts have been inundated because of lack of preparation, is not unknown. Obviously an investigation of local geologic conditions is a good precaution before planning any large work of underground development.

Korean Mining Ordinance

Recently we commented on the regulations governing, and restricting, mining by foreigners in China. Now we have before us a copy of the mining laws promulgated on December 24 last, and to be enacted on April 1, by the Japanese government in Korea. Evidently the new regulations are intended to be enforced as soon as it is apparent that the British and American governments will interpose no serious objection. After the Japanese armies had over-run Korea during the war with Russia, a pledge was given to withdraw in due course and a promise was tendered, at the instance of John Hay, representing the United States, that equal rights would be given to other nationals; in short, the policy of the 'open door' was recognized by Japan, meaning thereby that commercial opportunities in Korea would be rendered available to all nations on equal terms. Precisely the same understanding was reached with the British government, which in its treaty with Japan obtained recognition of "the principle of equal opportunities" as was duly recorded in a Japanese official publication in 1907. Just now, of course, the British government is too busy to bother about any commercial question with Japan, and the government at Washington is also somewhat pre-occupied, thanks to Villa and the submarines, so that not improbably sundry foreign secretaries will wake up one fine morning to discover that the 'open door' to mining in Korea has been bolted. It is true, the new regulations provide that those desirous of exploiting mines in Korea must incorporate a company under the laws of Japan, and this, it may be said, places everybody on an equal footing. But the Japanese authorities are well aware that British or American capital is unlikely to be placed in Japanese companies operating under such conditions, of attitude and discretion, as are outlined in this mining ordinance. For instance, the authorities can compel the employment or discharge of any "technical superintendent" they specify; they can demand that details of every plan for working a mine be filed in advance and become subject to alteration by the Governor General; the qualifications and duties of mine superintendents are to be regulated by the same official and he may examine the entire correspondence of any company. Many of the 64 clauses in the regulations are of such a restrictive nature as to deprive companies of all initiative and power of action in developing their mines. In case of two applications for a given property reaching the mining department on the same day, the Governor General is to issue the permit to whichever applicant he prefers. This would enable a clerk or other person in the office at Seoul to inform his friends that a foreigner experienced in mining had entered an application, giving particulars so that a second application could be filed on the same day. Under such conditions the foreigner would find it difficult to prove collusion or to obtain redress. The royalty to be paid by the holders of mining rights is 1% of the total value of the mineral output, together with a ground-rent of 25 cents per acre, to be paid in advance, annually. These exactions are not unreasonable, but "the total value" is to be decided by the Governor General, and any evasion or attempt to evade the royalties or ground-rent is punishable by a fine equal to three times the amount of the taxes involved.

If we compare these regulations with those in force in Australia, where the warden of a mining district is given discretionary powers in the administration of the leasing system, under which claims are worked there, and if we consider our own mining laws as they would appear to the detached view of a Japanese operator, we must concede that the terms of this ordinance are not without precedent. We in California have a 'blue sky' law whereby the Commissioner of Corporations can exercise a paternal restraint on speculation at least comparable with that of the Governor General in Korea. But neither here nor in Australia is any official allowed such powers of interference as will be granted to him in Korea under this ordinance. Obviously the effect of the regulations will depend more on the manner in which they are administered than upon the rules themselves; conditions can be made comfortable or impossible according as the local government chooses. This introduces a factor of uncertainty highly prejudicial to foreign enterprise. Evidently the mining law enables the Japanese officials in Korea either to shut out the further participation of foreign capital in mining exploitation or to permit of it under conditions agreeable to themselves.

And yet one point more needs to be mentioned. Our readers, having a sense of humor, will appreciate the position of an editor in California criticizing any action of the Japanese calculated to exclude American enterprise from Japanese territory, which Korea has become by a process of benevolent assimilation not unknown in the history of European expansion, in Asia, for example. The people of California, by its legislature, set out to prevent the holding of real property in this State by

Japanese individuals or by Japanese controlled corporations. The government in Korea has not gone quite so far. We would be handicapped in our protest if Japan had not broken both the spirit and the letter of a contract with the United States and of a similar contract with Great Britain. On the basis of those contracts we are justified in demurring to an ordinance that appears meant to exclude further foreign participation in Korean mining enterprise.

The Way of the Reformer

We have been favored with a copy of the correspondence between a mining engineer in Utah and the secretary of the American Mining Congress. This exchange of ideas, developing into a friendly controversy, presents several features that are of general interest. In the first place Mr. Engineer demurs to the inclusion in a committee of any persons either not connected with mining or of those known to be identified with disreputable phases of that business. He objects to making mining operations a mere excuse for share-dealing of an irresponsible kind. He refuses to identify prosperity with a swarm of wild-cats. He is all for scraping the barnacles off the good ship of which he considers himself a responsible officer. He would jettison the lawyers, brokers, promoters, and others that exploit, not mines, but men. Finally, he pours the vials of his scorn on a circular that describes mining "as safe as the manufacture of boots and shoes, when skill and capital are applied to its operation." All of this strikes a sympathetic chord, compelling us to sit back and applaud this Don Quixote of the salt marshes. Then comes the courteous reply of the Secretary, beginning with the disarming statement that a particularly objectionable individual, mentioned by Mr. Engineer, had been refused membership. Don Quixote is told that he ought to join the army of reform instead of tilting at wind-mills; he is assured that the Mining Congress is endeavoring to check just the kind of fraudulent mining of which complaint is made; and he is informed that any effective campaign has been hindered by lack of financial support from Mr. Engineer and his top-lofty friends. As to the creation of a bureau empowered to scrutinize prospectuses and the like, Mr. Secretary is of the opinion that there are already too many "holier than thou" organizations willing to criticize but unwilling to take action in bringing punishment to "those who prey upon the public." Whereupon Mr. Engineer answers less truculently, but he jibes at some of the members of a local committee of the Congress and suggests that "to have such people posing as guardians of the public weal is a pathetic joke." As to financial support, he shies at the suggestion and contents himself with a hint that the operations of the Congress do not appeal to a business man. He jumps on the 'manufacturing' idea of mining and enjoys himself while he lashes at a pathetic fallacy. Here he gets Mr. Secretary in a tight corner and tells him a few home truths in regard to the sport of mineral exploration and the essential risk of mining. The money put into mining is usually the surplus of the wealthy, to whom the idea of safety does not appeal in equal degree to that of luck. From the moral altitude reached by way of the superior insight thus outlined, Mr. Engineer proceeds to tell Mr Secretary what he ought to do: re organize, decrease the local council to a small number of Class A persons, who shall inquire into local mining flotations and expose them, when fraudulent; the Congress to publish the reports from its local councils, and sell this record for $10 per annum; Mr. Engineer will subscribe and get ten others to do so. As to libel suits, they will be few, and of those only a rare one will come to trial. It must be confessed that Mr. Secretary is given a stiff dose, but he takes it like a hero. His reply proves him a diplomat. Expressing appreciation of Mr. Engineer's suggestions, he retorts politely that the Mining Congress has suffered from the fact that men like Mr. Engineer, with definite ideas and the courage of their convictions, have held aloof because some others of its members did not reach their standard. To be effective in influencing legislation the Congress must have a larger membership than would be possible under the exclusive ideas of Mr. Engineer. The control is now in the hands of the kind of men approved by the aforesaid critic and the present standing of the organization testifies to this fact; so says the Secretary. After that the correspondence fades into amiable commonplace. We have given the outlines of the more intensive proportions of it because it expresses points of view often heard around the camp-fire, the hotel lounge, and the club bar. It exhibits the difficulties to be encountered by the reformer. The chief of these is the obtaining of financial support without loss of character. Needless to state we are saying all of this on our own initiative. If we had the say for a few minutes we would give the Mining Congress an income on which it could proceed to enlighten legislatures, prosecute fakers, and educate the public. The only trouble would be that a number of other organizations would make life miserable for us with claims for similar support. Joking apart, the first need of the Mining Congress is regular financial support. It has done good work in getting us the Bureau of Mines and it has undoubtedly stimulated the Post-Office authorities in checking the use of the mails for fraudulent purposes. Other good work could be instanced; for example, as regards the mining law and forest reservation. If some measure of financial contribution could be forthcoming from the industry at large, as, for instance, by a regular donation from all the dividend-paying mining companies, each contributing a relatively small amount, it would be practicable to lift the Congress into a position of greater usefulness. There is need for some such organization. Superior as the engineering societies are in many ways, they are inferior as reflectors of the public at large; they are essentially professional; and the business of mining is more than that. In its varied phases it is an art, a profession, a business, and a trade; yet in the end the artificer, the professional, the business man, and the trader alike depend on public support, and to get that mining must be legitimate and productive.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Flotation for Cinnabar

The Editor:

Sir—In view of the present high price of mercury and the frequent references to mercury ore in your columns it may interest your readers to know that cinnabar can be treated very successfully by flotation. The difficulty in treating this ore by mechanical concentration seems to be that with coarse crushing the large particles of cinnabar are for some reason thrown or floated into the gangue, although a good saving is made on the fine material, while if the whole ore is crushed fine before tabling, some of the mineral is reduced too fine to be held on the table and goes off in suspension with the tailing.

By crushing the ore to pass 60-mesh we have succeeded in obtaining very high recoveries by flotation, both with the Minerals Separation type of machine and also with the Callow. For instance: a sample of Californian ore assaying 0.1% mercury, crushed to pass 60-mesh and floated, gave a tailing of 0.01% as reported by one assayer, and zero as reported by another, showing 90% and 100% extraction, respectively. The amount of concentrate recovered was 2.17% of the original weight and assayed 4.15% mercury, but as a high-grade product was not required, no attempt was made to raise the value above this point.

A sample from another district in the same State assayed 0.3% mercury, and when crushed to pass 60-mesh and floated, gave a concentrate assaying 26.8% mercury in 1.12% of the original bulk with a tailing of 0.03%, showing a recovery of 90.95% of the content.

A sample from a third district assaying 0.92% had to be crushed to pass 80-mesh to obtain the best results. This yielded a concentrate containing 18% mercury in 4.78% of the original bulk, with a tailing of 0.06%, giving an extraction of 93.7%.

Mine Accident Insurance

The Editor:

Sir—The editorial in your issue of April 1 on this subject deserves a reply. I asked the manager of the State Compensation Insurance Fund, Mr. C. W. Fellows, to write me a memorandum. This is his reply:

"It is said that the State has upheld excessive rates for compensation insurance covering mines. The facts are clearly not in accord with this statement. The Workmen's Compensation Service Bureau of New York established a rate of $7.86 for mines in California and in 1914 this rate was followed by practically all the corporate companies. In the latter part of that year the State Compensation Insurance Fund withdrew its co-operation with the Bureau on mining rates and, after an exhaustive study of statistics, found that the pure premium cost, with necessary loading for expense and catastrophe, showed a necessary rate of 5%. When this rate was quoted by the Fund, the Bureau followed by meeting the figure. Some of the corporate companies, however, refused to take the business at that rate, but one well-known insurance company and the Commonwealth Bonding & Casualty Insurance Company of Texas made a strenuous bid for the business. The "well-known insurance company" finally took most of it at a rate of $3.25. Some risks were written at even less rate by the Commonwealth. The result of this reckless underwriting is indicated by subsequent events. The Commonwealth failed miserably, leaving thousands of dollars of unpaid liabilities and many employers and employees unprotected. The recent examination of the "well-known insurance company" by the California Insurance Department (not the Industrial Accident Commission) showed that the company's losses and expenses, based upon the estimates of its own experts as to unpaid claims, amounted to 117% of its premiums. In other words, it has paid or must pay $1.17 for each dollar collected. That experience covers its entire compensation underwriting, and as the mining business was written at a greater cut than other lines, it is safe to assume that its experience on mining business will show a much greater loss ratio than its average on all classifications. Is it reasonable to assume that the two companies are 'perfectly solvent and reliable'?

"These two very apparent results of rate-cutting, which are inimical to the interest of the public, are sufficient justification for the Uniform Rating Statute. This statute merely vests in the State the right to judge from actual statistics the adequacy or inadequacy of rates for the protection of the public against insolvency of insurance carriers. The statement that rates are higher because of State supervision is not borne out by history. Had the State not entered the field, the mining interests would be paying much more (as in 1914) for this insurance than at present. This is demonstrated by the fight which has recently been waged by the Workmen's Compensation Service Bureau to secure the approval of the Insurance Commissioner to a material in-

crease in mining rate, the Bureau insisting that the $5.75 rate is inadequate. Because the State Compensation Insurance Fund has the only reliable statistical data on the subject, it has been able to keep the approved rate to $5.75, as against a rate of $7.71 suggested by the Bureau.

"The State Compensation Insurance Fund operates on the principle that it must collect a premium which will meet all contingencies, but as its expenses are less than other carriers, it has been able to return substantial refunds to policy-holders."

In the foregoing statement Mr. Fellows has clearly outlined the situation from an insurance man's point of view. I am especially interested in the discussion because of the "good-will and co-operation that seems assured between the mine operators and the Accident Commission," to quote your editorial. This co-operation is exemplified in the friendly spirit shown toward the work of the Commission's Safety Department. One important factor in reducing insurance rates is the prevention of injuries in the mining industry of California. Insurance rates are based on the hazard of the occupation and the Industrial Accident Commission is sure that the 'Safety First' agitation will prove successful. One noteworthy indication of this is that in 1914 there were 66 deaths in mining operations in California, and in 1915 there were 60 deaths.

The rates quoted by the State Insurance Commissioner are only tentative rates. If a fuller experience shows that a larger premium was received than was necessary, the State Compensation Insurance Fund will return the excess to mine operators who insure with the Fund, just as has been done with other employers since January 1, 1914. Other insurance carriers can also refund excess premiums, if their financial condition, in the judgment of the State Insurance Commissioner, warrants the course. This plan provides for mine operators paying the actual cost of their insurance and no objection can be raised to this plan. The solvency of insurance carriers is so important that employers and employees should join hands with the State authorities in an attempt to prevent the distressing experiences that have followed the failure of the Commonwealth Bonding & Casualty Insurance Company.

WILL J. FRENCH,
COMMISSIONER.

San Francisco, April 6.

Antimony Gold Ore

The Editor:

Sir—Relative to your foot-note to Mr. Wm. Seward Mann's letter on the 'Treatment of Antimony Gold Ore,' which appeared in your issue of March 25, the difficulty in treating West Gore antimony-gold ore was not the removal of the caustic soda, prior to cyaniding, but that, in parts of the mine, the ore carries a large proportion of metallic antimony, which is not soluble in caustic soda, and which, remaining in the pulp, formed a precipitant for any gold that the subsequent treatment with cyanide dissolved, and thus prevented its removal from the pulp.

The process, which was devised by Mr. J. S. MacArthur, is one of those exceedingly interesting ones in which the reagents used are rehabilitated, and, it would seem, should work both economically and well on an ore free from metallic antimony. The following was the method Mr. MacArthur used: The pulverized ore was leached with a 2% solution of caustic soda until the sulphide of antimony was removed, thus:

$$Na_2CO_3 + CaO + H_2O = 2NaHO + CaCO_3$$

Carbon di-oxide formed by the burning of limestone, was passed through the antimonial solution, precipitating the metal as sulphide, thus:

$$Na_3SbS_3 + Na_3SbO_3 + 3CO_2 = Sb_2S_3 + 3Na_2CO_3$$

The solution was removed from the antimony sulphide by decantation and filtration, and converted into sodium hydrate, ready for use again, by caustic lime:

$$Na_2CO_3 + CaO + H_2O = 2NaHO + CaCO_3$$

Limestone is generally too cheap a commodity to make it worth while carrying the rehabilitation further, but, if necessity should arise, the caustic soda can be decanted from the carbonate of lime, and the latter burned, giving CO_2 to precipitate more antimony sulphide and CaO to re-vivify the carbonate of soda formed.

Sulphide of soda was also tried on West Gore ore, and, with protracted contact, was found to dissolve metallic antimony, by first coating the particles of metal with sulphide, which, in turn, was dissolved in excess of the reagent. Unfortunately, however, the sulphide also dissolved a marked quantity of gold—about 20%— so the use of it had to be abandoned.

I notice from the annual report of the Department of Public Works and Mines for Nova Scotia that the West Gore mine, after being closed for a number of years, was re-opened in October, 1914, and last year from 10,782 tons of ore, produced 783 tons of concentrate, which contained 1698 ounces of gold.

F. H. MASON.

Panama California International Exposition,
San Diego, Cal., April 1.

NEVADA, with a population of 100,000, had a mineral production in 1915 of over $35,000,000. Its area is 110,700 square miles, which is nearly twice that of Wisconsin, but the population of the entire State is less than that of Salt Lake City, Tacoma, or San Antonio. Nevada's population of less than one person per square mile is the smallest of any State in the country, comparing with 18 per square mile in California, 50 per square mile in Michigan, and 500 per square mile in Rhode Island. Nevada's production of copper for 1915 rose in value to that of its gold production, each being slightly under $12,000,000, while its production of silver was valued at $8,000,000. Nevada ranks with Montana as the premier silver-producing State. The output of zinc increased rapidly in 1915, particularly in the Yellow Pine district and at Pioche.

The Need of a Change in the Patent Law

By James M. Hyde

IN order to promote the invention and adoption of such improvements as are necessary to the best development of the industrial arts, our Government early adopted the policy of granting monopolies to the use of such improvements to inventors for a period of years. This policy is based upon the assumption that the possible possession of such a monopoly of the profit to be gained from the exploitation of an invention will act as a stimulus to those who have inventive capacity, inspiring them to devote their time and resources to devising and perfecting improvements in apparatus and processes valuable in the arts and sciences, and causing them to make public the details of their inventions so that when the patent expires the public may have full knowledge of the invention and may therefore be able to make use of the same; and that the possession of the temporary monopoly will make it possible for the inventor, either by his own efforts or by the efforts of others, to reap such profit from his invention as to warrant the expenditure of the time and money necessary to foster the general adoption of the invention.

As our system now works out, a patent does not, in fact, establish its possessor in a monopoly of his invention. One of our greatest inventors, Thomas A. Edison, is credited with the statement that "a United States patent is nothing more than an introduction to the highest courts of the land," and anyone who has been introduced into that exclusive society realizes the expense which such an introduction entails.

The present position as regards patents is, in brief, about as follows: When one has devised some method or apparatus that he conceives to be new and of such possible value as to warrant obtaining a patent upon the same, he obtains the services of a patent attorney to assist him in the proper filing of his papers and the presentation of his case before the United States Patent Office. For some time past, the standard cost of obtaining a patent has been $75. Of this amount $35 must be paid to the Patent Office in fees and $40 is paid to the patent attorney for his services. The ease with which patents may be obtained is indicated by the meagerness of the patent attorney's fee, and by the further fact that many firms of attorneys guarantee either to obtain a patent or to make no charge for their services. They are entirely safe in doing this, as it is practically always possible to make some modification of an idea, deviating in some slight degree from that which has been done in the past, so that it will be patentable, even though it may be of no value. The patent obtained may not in any way cover the apparatus or process that will actually be used or marketed by the alleged inventor, but he nevertheless may obtain a patent or series of patents upon which to base claims of patent rights and give him so-called 'talking points.'

When the inventor has obtained a patent he has no means of preventing the infringement of it, except by suing the alleged infringer in a U. S. District Court. Likewise, the individual who believes that a patent is invalid and wishes to challenge its validity has no means of doing so except by infringing the patent and permitting himself to be sued for infringement. If the trial of the issue in the District Court were finally to settle the question of the validity of the patent, the system that is now in use would not be so onerous; but, unless the parties to the suit compromise the issue after the case is decided by the District Court, the case is almost certain to be appealed to a United States Circuit of Appeals, if rights of great value are involved. If the decision of the Circuit Court of Appeals does not lead the litigants to come to an agreement, the defeated side will usually apply for a re-hearing of the case, and if that be denied will appeal to the United States Supreme Court, which fortunately rarely entertains such issues unless a new suit for an infringement has been brought in a different District Court, and appealed to a different Circuit Court of Appeals which has granted a different decision from the Circuit Court of Appeals that first passed upon the case.

There is no one court in which patent cases are heard and which finally passes upon and disposes of them. Infringement suits may be filed in any of the Federal District Courts in the United States, and a patent involving valuable rights is generally made the basis of suits in at least two District Courts and two Circuit Courts of Appeals if one or the other of the litigants is particularly litigious.

Because of the use of high-priced attorneys and expert witnesses on each side, the compilation of elaborate printed records and briefs, the adroit handling of the technicalities of the law, and the necessity of finding a date for the hearings upon the calendars of courts crowded with other matters, the decision as to whether an alleged invention is really patentable may be made to consume years of time and involve enormous expense. Such a system defeats the very purpose of the patent law, which is to foster the rapid development of industry. No adverse criticism of our courts is intended by this statement. The courts do the best they can with a situation of which they are in no sense the creators.

The Patent Office was instituted to determine whether or not alleged inventions are entitled to governmental protection, and to issue patents to those who are entitled to the same. It should be the duty of the Patent Office, and the Patent Office alone, to pass upon the patent-

ability of alleged inventions. The Patent Office is not now so constituted and empowered that it can properly perform this, its only proper, function. The changes in its organization that must be made to enable it to perform its true function fully must be enacted into law by Congress, and will be so enacted by Congress only when that body is persuaded that the interests of the country demand it.

Among the changes that have been proposed by those who realize that our present system, instead of fostering the development of industry, places almost insurmountable obstacles in the way of the development of industry, the extreme proposal upon one side is that the search made by the Patent Office shall be so thorough and complete that a patent when granted shall in itself be *prima facie*, incontrovertible evidence of the right of the patentee to the monopoly alleged to be granted by the patent. This proposal naturally is popular with many inventors, with certain members of Congress, and with certain other individuals who have little real knowledge of the difficulties encountered in the just administration of a patent system. The alternative extreme view is that the Patent Office should combine the functions of a bureau of records, in which the inventor may record what he conceives to be the essence and extent of his invention and the date upon which his invention has been made, and an office that shall finally grant a patent only after the patent has been passed upon by the Courts, before which the patentee defending his patent and an interested party contending against the granting of the patent shall have fought out the issue. This proposal is based upon the assumption, which is undoubtedly true, that such an investigation as will determine whether or not an alleged new invention is really novel, the invention of the alleged inventor, and properly entitled to the protection of a patent, can be made only when a contest takes place in which the patentability of the invention is defended and attacked by contending parties having much at stake. The unchallengeability of this assumption should not be taken to mean that no patent is to be granted until the full gamut of the Federal Courts has been run, as is now necessary. It is natural that this solution of the problem has been brought forward by a patent attorney.

The first of these two propositions, that is, that the Patent Office should grant a patent which when once granted shall be unassailable, is untenable because it is absolutely impossible that any investigation depending upon a search in printed records alone, and more particularly in the records of the United States and other Patent Offices, can ever determine that an alleged new invention has not previously been made known and put to use. Anyone who has ever had occasion to make a technical investigation must realize that if the most expert assistance obtainable were used in such an investigation, the paltry sum of $35, which constitutes the whole Government fee, would be absolutely inadequate to meet the cost of gathering the information desired. The United States Patent Office is reported to have accumulated a large fund from that part of the fee which is charged for patents, and which has not been expended in carrying on the Office's work; if this be true, it only confirms the assumption that the investigations now made afford a hopelessly inadequate basis upon which to grant countless absolutely unregulated private monopolies.

So large a part of the arguments with regard to the necessity of the modification of the patent law have been made by inventors or patent attorneys that the rights of the public have at times been almost overlooked.

There are no more fundamental human rights than the right of the individual to use for his own benefit all of the knowledge that he may possess; and the right of the State to control and even curtail the rights of the individual in the interest of the rights of the whole public.

A patent is a monopoly granted to an individual for the exclusive right to the manufacture and use of an improvement for a fixed period of time. Concurrently, it is a denial of the right of the public to make free and unrestricted use of such improvement during the life of the patent. Our experience during the past few years has so clearly demonstrated the extent to which the public may suffer from unrestricted private monopolies that we have adopted, as a governmental policy, the curtailment of the development of monopolies and the careful governmental regulation of such monopolies, or near monopolies, as are permitted to exist. It is indeed remarkable, that in the face of the prohibition, or careful supervision, of monopolies as a well accepted governmental policy, our Government is itself, through the Patent Office, in a hit-or-miss fashion, annually creating thousands of absolutely unregulated monopolies of the most valuable kind—the improvements in the arts and sciences that are the very foundation of material progress. To deny or curtail the right of the public to the free use of an improvement in the arts is a very grave matter, and should never be done on inadequate evidence.

The law provides that a patent may be granted to the inventor covering the use, manufacture, or sale of an improvement of apparatus or process. Evidently this is done upon the assumption that the inventor has rendered a benefit to the State by perfecting his invention and making the invention known in its essential details to the public. By many inventors and patent attorneys it is claimed that the rights of the public are not abridged by a patent, as the invention is a thing that did not exist until it was invented by the patentee and in which the public could consequently have had no rights. The history of patent litigation shows that the Patent Office frequently grants to individuals monopolies of that which is already the property of the public; and experience has shown that while certain inventions are attained only after the most careful study and the exercise of great technical knowledge and ingenuity, probably the majority of the improvements made in the arts are the direct outcome of that which has been done before, the logical and necessary next step forward that would be taken by any one of a number of minds dealing with that art. Improvements of this kind should be distinguished from those requiring the exercise of real inven-

tive ingenuity. Industrial work becomes involved to an absurd degree, when every minor and obvious improvement can be made the subject-matter of a patent.

Fortunately, it is not the universal practice of those engaged in the applied arts to take out patents upon all of the improvements in machines and processes devised and used by them; consequently, the records of a Patent Office cannot be a complete record of all the improvements that have been made in the arts. Similarly, although our great body of technical literature is more and more being made a record of the details of machines and practices in use, there are, nevertheless, many improvements in machines and processes that have not been described in technical journals, even though they have come into regular use. It is therefore impossible that the Patent Office can ever be expected to make such a complete search as actually to determine that an alleged invention is so certainly novel that its inventor is entitled to a patent which when once granted can never be challenged. We know, through the fact that many of the patents granted by the Patent Office are held to be invalid by the courts, that the search now made is an absolutely inadequate basis upon which to abridge the right of the public to make free use of a useful apparatus or process.

It is obvious that the solution of our problem is not to be found in having the Patent Office grant irrevocable patents on the basis of its own unaided investigations.

In certain countries every application for a patent is published and anyone having rights which he considers would be unjustly curtailed has a right to file a protest against the issuance of the patent. In Germany, where this system is used, the exact subject-matter of a patent that is causing years of most costly litigation in this country was embodied in an application for a patent which was contested and after a very brief hearing was refused by the German Patent Office.

While the publication of applications for patents would protect the interests of the public to some extent, even this added precaution would not warrant the granting of irrevocable patents, as it would be very likely that no one would be sufficiently alert to object to the issuance of all of the patents that are not novel for reasons which do not appear in the materials referred to by the Patent Office.

As has been previously stated, it is possible, under our present system, that before the validity of a patent can be finally determined, litigation may have proceeded for many years. There have been cases where a patent was not finally held to be valid until within a few months of the time when it expired. This lengthy litigation is extremely costly. It is so costly that a poor inventor cannot possibly maintain his own rights in court without assistance, assistance which usually means the assignment of a great part of the profit possibly to be derived from his invention to those who will uphold his rights. The system as now administered does not fully promote the rapid development and adoption of improvements. Many a man is diverted from the exercise of his inventive talent by the fact that he knows that, if he expends the time and money necessary to perfect valuable inventions, he will, if poor, be absolutely at the mercy of those who possess more means and thereby dare infringe his rights, and of those who possess more means to defend his rights and can therefore deprive him of the ownership of his invention for the money necessary to defend it. Even where the inventor has the temerity to perfect his invention and go to the expense of patenting it, our present system makes it difficult for him to get his invention adopted, as the uncertainties as to the status of a new patent and the cost of defending the same will prevent many who could profit from the use of an invention from adopting it. The second alternative position originally stated, that is, that patents be granted only after they have been litigated, cannot be upheld if the decision with regard to the granting of the patent is to be based upon fighting out the issue before our Federal courts, as is now done.

What we need most is to get away from the cost and lengthy delays involved in fighting through all the Federal courts of the land to decide whether or not an alleged inventor is entitled to a patent for an alleged invention. There is no reason why the Patent Office cannot be so amplified and empowered that it will finally, expeditiously, and economically dispose of all questions as to the patentability of inventions. It is the logical function of the Patent Office to do this one thing.

Usually it takes but a few hours at the most to explain thoroughly and convincingly, to a man of technical and legal training, the issues of a case that will take several years and the expenditure of a fortune to determine in the law-courts. This is highly uneconomic and absolutely opposed to the best interests of the State, the interest of which can only be fostered by doing all that is possible to promote the perfection of industrial improvements and their rapid adoption. An office that would quickly and finally determine the validity of patents and grant patents that when once issued would be unassailable evidence in determining rights in the Civil courts would protect all who have legitimate interests and thereby foster the most rapid material development of the State. At the present time patents are annually granted by thousands and it is absolutely impossible for anyone to determine whether or not a patent is valid or exactly what it can be held to cover, until a lengthy course of litigation has been gone through. This is nothing but governmentally created confusion, and a businesslike people, used to handling its affairs with sanity and dispatch should not endure the continuance of such a system but should bring about the adoption of a system by which matters of such importance can be settled with ordinary business dispatch.

A careful study of the situation created by our present system, which may have fitted a day when inventions were few and simple, but is entirely unsuited to the present complex of industry, has made it apparent that a few simple modifications would remove most of the unnecessary evils.

As a search is necessary both in the interests of the inventor and the public, a search should be made, but it

should be much more exhaustive and more prompt than is now the practice. To facilitate this work the Patent Office should have more adequate quarters, better library facilities, and a larger staff. If it is necessary to charge a higher fee to enable the Office to do its work better, it should be done. Such salaries should be paid to the examiners and assistant examiners as to retain more trained men in the service. The force of each division of the Office should be kept at such a point that not more than a month at the most should elapse between the time an application is filed and the first report upon it is mailed to the inventor. These things are necessary in the interest of the inventor, so that he may learn as promptly as possible whether or not it is probably worth his while to continue his work in perfecting and patenting his invention. The patent, issued after the best possible office search has been made, should be tacitly considered to be tentative, which is all that a patent as now granted is in reality. It should have a status differing from that now given to a patent, in that no injunction should be based upon a patent and no damages should possibly accrue from the infringement of a patent until its validity has been finally established.

It should be the policy of the Patent Office not to grant patents upon such differences in process and apparatus as would naturally be made by a skillful operator. Our present confusion results in part from the fact that patents are freely issued on obvious and minor deviations from practice, and later, after costly litigation, are properly held by the Courts to cover only such modifications as one skilled in the art would be expected to make, and are hence not patentable. The examiners need to be thoroughly impressed with the fact that while the inventor should be allowed all that he is justly entitled to, it is their duty also to see that the rights of the public are not unjustly abridged or jeopardized.

As it is inherent in the nature of the case that a final determination as to the patentability of an invention can only be reached when there is an incentive to those whose rights will be abridged by the patent to fully represent their rights and for the applicant for the patent to do the same, and as it is the proper function of the Patent Office to investigate the patentability of alleged inventions and grant patents when they are deserved, a Patent Court should be an integral part of the Patent Office and all questions as to the patentability of improvements should be cheaply, promptly, and finally determined by this court.

The judges of this Patent Court should be so adequately paid that their continuance in the Government service would be assured. They should be men familiar with the patent law and of such technical training and experience as to be able to comprehend the technical issues coming before them. The rules governing the conduct of cases before the Patent Court should be extremely simple. The rules governing the California Railroad Commission, which is able to turn out an amount of work never approached by the law-courts, because it does not permit of elaborate and involved procedure, could well be made a model for the rules governing the conduct of cases in the Patent Court. The procedure should be so simple that it would be possible for any inventor desiring to do so to personally represent his own case. If any expert testimony should be found necessary for the clarification of issues being tried before the Court, the Court should appoint its own expert to investigate and report. The system of expert-witnesses now in vogue is absolutely indefensible.

Such a court as that which has been herein proposed should be able to dispose of practically every case in one hearing. It would be constituted of men to whom neither the patent law nor the nature of the technical questions involved in a patent suit would have to be interpreted, and who would, because of their expert knowledge and experience, determine promptly where justice lay.

The decision of this Court as to matters of fact should be final and no appeal from its decision should be possible save as to interpretations of the patent law, and the Appellate Court to which such matters might possibly be submitted should also be an integral part of the Patent Office and should be the court of last resort for all questions concerning the patentability of inventions.

It should be possible to bring the question of the validity of a patent before this Court, either by a suit for infringement or by a petition to have the patent declared invalid for reasons properly set forth. In either case anyone desiring to be heard should be permitted to submit evidence, as it is not always to the interest of contending inventors to present all of the evidence which is obtainable.

The majority of patents are of so little consequence that they would probably never come before this Court. Its membership should, however, be sufficiently large, made up of men of sufficiently diverse technical and legal training and so divided into divisions sitting independently in Washington or elsewhere that all questions would be disposed of by it promptly; and it should be specifically provided, that whenever the Patent Court had so much work to do that cases could not receive prompt attention, more judges should be appointed, as it is absolutely necessary to the interests of industry that matters of this kind be decided promptly.

It is entirely prejudicial to the interests of the State to have the adoption of an invention delayed unnecessarily; and no greater financial loss can be inflicted upon an inventor than to deprive him of the enjoyment of the profit of his invention during a considerable part of the period for which his patent is granted.

Those who profit by our present system have usually been well represented before the congressional committees investigating the necessity of the modifications of the patent law. If the rights of the public are to be protected it is necessary that the attention of the individual members of Congress be drawn to the radical changes in patent law which are needed and that committees representing the great technical societies should go before the patent committees of both houses of Congress to urge the adoption of the changes necessary if the interests of the public are to be safeguarded.

Washoe Reduction Works, Anaconda—III

By L. S. Austin

The Slime-Flotation Plant

The overflow from the two 7-ft. Anaconda classifiers in one unit of the concentrator amounts to 400 tons daily, containing 2.5% copper from a 3% ore. This product is now sent to the thickener plant, thence to the round-table plant, where 53% of its contained copper is recovered, the tailing of that plant being run to waste with 1.1% copper still retained. It is for the purpose of making a closer recovery, so that but 0.25% copper shall be left in the slime-tailing that an additional flotation plant is being erected. This is situated midway between the thickener plant and the round-table plant (see the general map, Fig. 1). It contains the mechanical agitators of the Minerals Separation Co. The frothed concentrates, discharged from these, will flow to the boot of the bucket-elevator in the central elevator-tower, and will thence be laundered by gravity to any one of the five 50-ft. thickener-tanks and thence by elevators to the Oliver filters to yield a moist slime-concentrate.

Referring to Fig. 8, the building, 147½ by 68 ft., is occupied by the Minerals Separation separators except the middle space where the elevators are, there being ten machines in each half of the building. The slimed pulp enters by launder to an overhead receiving-box, thence by a supply-launder to the various distributing launders and so to the heads of each machine. Note the slight grade of ⅜ in. per foot—enough for such fine material. As in the sand-flotation plant, the pulp goes through the 14 compartments of the agitator in series. There are no Callow machines in this building. The products of the M. S. machines are three, a spigot-discharge from the last compartment, which will go to waste, a concentrate from the first six compartments, a middling product from the remaining eight. Launders carry the concentrate to an elevator, the middling to another elevator at the centre bay of the building. The launders are so laid out that in case of break-down of either of these elevators it will only be necessary to re-set the controlling launder-gates in order to use the third or spare elevator to take its place. Steam is used for heating the entering pulp and for warming the building. The middling, of course, is returned to the head compartments of the agitators, while the concentrate passes by launder to the thickener-building, as already mentioned.

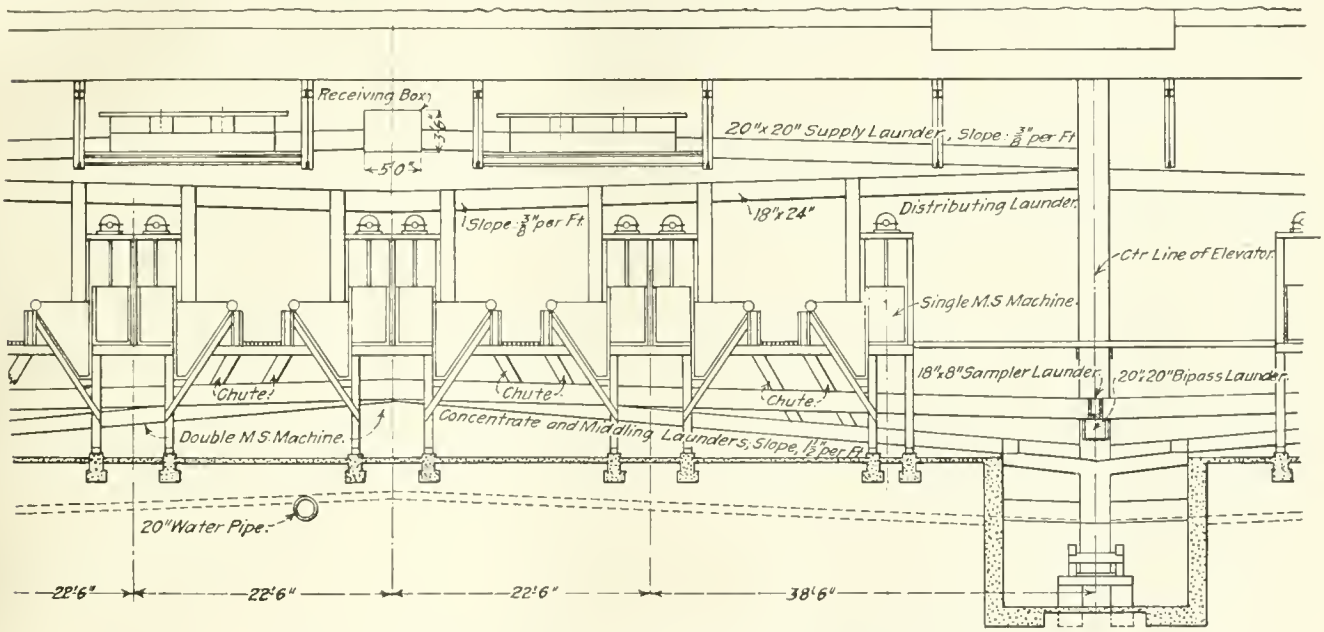

Fig. 8. Longitudinal section of part of the slime-flotation plant.

The Zinc Plant

A new undertaking of the company will be the treatment of zinc ores and the recovery of the zinc in pure form by electrolysis. Zinc ores of 20% or over are to be roasted if necessary to the production of sulphate, or if oxidized, then leached directly by the use of sulphuric acid, and the zinc precipitated upon stripping sheets. A few cathodes of hard lead are used for making these sheets. The anodes are of hard lead. A current of 40 amp. per sq. ft. is to be carried and the plant is to have an output of 10 tons of metal daily.

This 10-ton plant has been pushed to completion on account of the sudden rise in the price of zinc. Normally more time should have been spent in working out

the process in the one-ton plant that had been erected. It was felt, however, that the pressing forward of larger-size operations was justified. The installation includes not only the building called the zinc plant, but the zinc-plant power-house, the latter adjacent to the leaching plant.

Nor has this been all: To supply electric energy the company has had available large motors and generators, not used at the electrolytic refinery at the old works. It had the use of the crushing equipment of the converter plant, now idle because acid-converter lining-material is superseded by the basic lining. A 10-ft. Hardinge mill, also on hand, has been utilized. It has been possible to employ two of the McDougall roasters of the leaching plant close-by with all conveniences for cheaply moving and storing ore. Electrolytic tanks were obtained from Great Falls, where they are being made by the hundred for the new electrolytic refinery now being constructed there. The company has sheet-lead already purchased at lower prices, also its own expert lead-burner. It has an Oliver filter and Garred thickener (filter), also motors, shafting, etc.

The tanks for the new zinc plant, purchased from a California firm and made of redwood, after erection needed no preliminary swelling by being filled with water, and did not leak.

In outline the process may be briefly given as follows:

Ore containing 14 to 20% zinc is crushed to 40-mesh; roasted in two McDougall roasters of the leaching plant; tank-agitated with a 6% solution of sulphuric acid, further agitated in the Mineral Separator Co.'s agitator of 14 compartments with additions of crushed limestone to neutralize the acid solution, and in a later compartment, with a little zinc-dust to get rid of copper, thickened at a Garred filter, the thickened pulp filtered by an Oliver filter, and the tailing run to waste. The solution, pumped from the Oliver filter, joins that from the Garred machine, the two being introduced into another Mineral Separator Co.'s agitator, and there further agitated with the addition of some zinc-dust for the precipitation of 0.1% of copper still remaining, and of cadmium. This turbid solution is successively settled in boxes and in a large tank, then goes to large storage tanks with filter-bottoms, from which a clear solution can be withdrawn to the electrolytic tanks.

There are six rows or cascades of tanks, each cascade consisting of seven tanks set on a descending grade, so that the solution can flow from tank to tank. In each are 22 cathodes and 26 anodes, giving 924 cathodes in all. At the end of each cascade is a Pohle air-lift of lead, by which the flow is lifted to the head of the next cascade adjoining. The flow is thus through the whole six cascades of the system. The entering stream is to carry 5% zinc and no free sulphuric acid, and to leave the tanks still retaining 3% zinc and 6% acid. This removal of not half the zinc is all that is considered prudent, since the acid is there developing ready to redissolve the zinc from the cathodes. The current is delivered at a density of 30 amp. per sq. ft. The drop between anode and cathode, with about a 2-inch interval, is 4.28 volts, or a total pressure of 90 volts with 8000 amp. representing 720 kw. With sheets 2 by 3 ft. this represents 360 amp. per sheet. The anodes are of pure chemical lead. The starting sheets, made in several of the cells, are deposited on aluminum cathodes and are built up about ¼ in. thick, weighing 10 lb. each.

The electrical equipment, installed in a separate power-house, consists of three motors and six generators. Each motor drives two generators by a rope drive. Each generator is built for 270 kw., or for the six, 1620 kilowatts.

The 2000-Ton Leaching Plant

Two years ago Frederick Laist presented a paper at the Butte meeting of the American Institute of Mining Engineers (Vol. XLVI, pp. 362 to 382) on the subject of leaching tailing at the Washoe works, with a description of the experimental plant for the chloridizing roasting, and leaching of the tailing. At the Salt Lake meeting of the Institute in 1914, he together with H. W. Aldrich had a paper entitled 'Experimental Leaching at Anaconda' describing an 80-ton experimental plant, the fore-runner of the 2000-ton plant now fully in operation at the Washoe works, the subject of this article.

The process in brief is to subject tailing that has accumulated for years, and that contains 0.50 to 0.65% copper, to a brief roasting at a temperature calculated to convert the copper sulphides into sulphate and oxides. The resultant roasted product is leached with additions of dilute sulphuric acid, the copper-bearing acid filtrate being sent to tanks, there to be precipitated on scrap-iron. The final precipitate of 55 to 70% copper is transferred for treatment to the anode furnace of the converter department.

Referring to the group of buildings at the south-east side of the grounds, there will be seen a small building (Fig. 2) marked 'unloading-bin,' having a railroad track threaded through it, and long enough to contain three 50-ton dump-bottom cars. The tailing, containing 4 to 6% moisture, is loaded into a train of three cars from a sand-tailing dump situated below the works and accumulating there for years. The train having been set within the building, its load is discharged through a grated floor, the bars of the grate having 2-in. openings. Frequently stones of fist-size and larger are thus sorted out of the sand. The tailing falls into a hopper-bottom bin of 300 tons capacity, shown in cross-section in Fig. 9, and is drawn off by 22 spouts at 4-ft. intervals upon short endless-belt feeders. These feeders are set in motion as soon as the cars are discharged, and the bin is emptied, the tailing being taken away promptly by a 36-in. conveying-belt. This 36-in. belt discharges upon another inclined one that raises it to command a double hopper-bottom bin of 6000-ton capacity in the 'storage-building,' Fig. 1, or as in Fig. 10, wrongly marked 'de-watering bins.' A movable tripper discharges it into any part of the 6000-ton bin as desired. Beneath this at 12-ft. intervals are spouts at the points of

the hoppers. From them a system of 18 feed-belts on each side (36 in all) delivers to a 24-in. horizontal conveying-belt extending the length of the building. The sand-tailing is withdrawn through any of the spouts as desired for supplying the leaching-plant.

As may be traced on the sectional elevation of the plant, Fig. 10, the course of the tailing is beneath tracks horizontally to the 'motor-house,' then by incline-conveyor to the top floor of the roaster-building. A parallel incline-conveyor takes coal and salt from the 'coal and salt building' also to this top floor. The tailing is moved the length of the roaster-building by two conveying-belts and by tripper is shot into any desired roaster-hopper to the right or left. The coal being in much smaller quantity is more simply transferred by car and put into the hoppers.

In the roasting department are 28 roasters of the McDougall type, in four rows; they are 20 ft. in diameter, having air-cooled shafts and arms. Each furnace has six hearths with fire-boxes on opposite sides of the third hearth. Coal from the hoppers is drawn off on the sheet-steel floor at this level, so that the boxes are hand-fired. The hearths are maintained at a low red heat (665°C.). The salt is not added to the furnace-charge but into the leaching-tank. The ore is fed to each furnace by an endless belt-feeder. On the first or upper hearth it is dried. On the second hearth no visible heat appears except the flame at the time of firing. On the third hearth there is a red heat, brighter at the time of firing, with some sparks. On the fourth hearth the charge is dull red, with an occasional spark at the passage of the rakes. On the fifth hearth visible heat had nearly disappeared; and on the sixth, where some air is admitted at the doors, an occasional spark may be seen, falling through the drop-holes.

Fig. 10 shows the position of the two lines of belt-conveyors for the calcine, one line to each two rows of furnaces. Before delivery to the conveyors the ore is first cooled, then moistened with water. To accomplish this, as the figure shows, a revolving inclined cylinder-conveyor 18 ft. long, parallel with the belt-conveyor, delivers the ore to another cylinder at right angles, the ore falling thence upon the conveying belt. The first cylinder is lined with ¾-in. cooling-pipes having circulating water, the ore arriving at the discharge-end properly cooled. Axially into the second feed-cylinder is spurted a jet of water that dampens the ore to about 1% of the moisture, thus preventing any loss of dust in conveying.[1]

To remove the furnace-gases each line of furnaces is provided with steel flues (as shown by circles in the roaster plant, Fig. 10), which lead the header at the south end of the roaster-building, thence into a steel stack 15 ft. diam. by 200 ft. high. The off-take at each furnace rises vertically into the steel flue.

In the leaching-building (see general plan, Fig. 1) are ten large leaching-tanks, 50 ft. diam. by 14 ft. deep, in two rows, and of 1100 tons capacity each. These tanks have a grated slat-bottom covered with cocoa-matting, the matting being held down and protected by wooden gratings having openings 4 in. square. There is a good reason for this, as the fibre of the cocoa-matting becomes weakened by the acid, and impact of the sluicing stream would tear it, were it not protected by the grating. This was inserted as the result of experience in the 80-ton plant. The tanks serve for ore-storage so that one of them is always in course of being filled while leaching and emptying proceeds in the others.

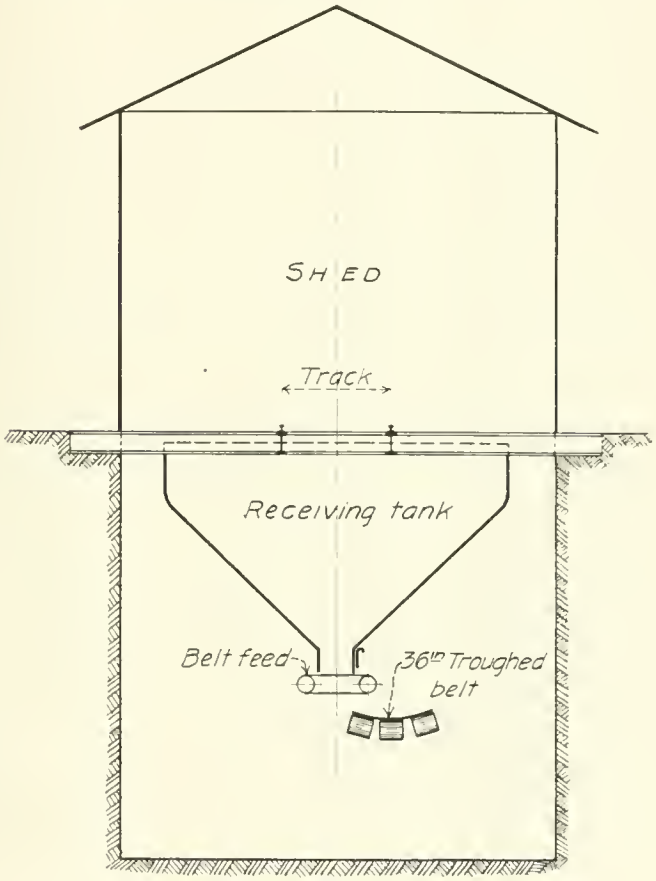

FIG. 9. UNLOADING BIN.

The calcine from the roaster-building is brought by either one of the two inclined conveyors, one delivering to a long horizontal belt-conveyor over the first row of tanks, the other to the conveyor over the second row. Each of these tank-conveyors has its own movable tripper; thus the whole flow from the roaster-plant can be delivered to any desired tank.

We come now to the method of distributing ore into a tank. There are two traveling bridges, one over each row of tanks, and each bridge set, when filling, over the centre of the tank, carries a distributer of 100 tons hourly capacity. The distributer is a framed truss hung at its centre from the bridge and revolving about a vertical axis so that its arms reach the periphery of the tank. The ore, falling from the tripper, is received on an endless-chain scraper-conveyor, which moves outward toward the circumference. In so doing it drops

[1]This double arrangement seems to the writer more complicated than needful for the purpose to be attained, but he is bound to say that it is the result of careful experimenting.

the ore through openings regulated by slides, each opening being so adjusted as to give the proportion needed for filling the tanks evenly.[1] When leaching has been completed, the contents of the tank are hosed out through five bottom-discharge valves in about 8 hours, using two hose-lines with nozzles of 1¼ inch diameter.

Adjoining, and at a level 17 ft. below the floor of the leaching building, so that the tanks can drain to them, is the shed containing the five solution-tanks, 50 ft. diam. by 11 ft. deep, of 800 to 900 tons capacity each. From these tanks, by means of centrifugal pumps, the solutions are sent to any desired tank. Counting from the north end of the building, the tanks have stored in them the following enumerated solutions.

In No. 1 tank, No. 1 solution containing 5% H_2SO_4 and 8% NaCl.

In No. 2 tank, No. 2 solution containing 1% H_2SO_4 and 8% NaCl.[2]

In No. 3 tank, copper solution containing 1½% H_2SO_4, 2% Cu, and 8% NaCl.

In No. 4 tank, storage for the wash-water from the leaching-tanks. This wash-water would, of course, contain a little acid, salt, and copper.

In No. 5 tank, also a storage for the wash-water, as in No. 4.

The following is the order of treatment when leaching a charge: First there is run on top of the filled tank 250 tons of No. 1 solution. This sinks through the ore and drains to the copper-solution tank and thence in a regulated flow to the scrap-iron launders or vats. The outflow from the launders goes back to No. 2 solution-tank, deprived of its copper, but containing basic salts of iron and alumina. It is consequently necessary to waste some of this solution in order to keep down the contents in basic salts, which tend to precipitate where built up to over 1½% in the solution.

Second. Salt is added to the extent of 15 tons per tank from a salt-bin at the foot of an inclined belt-conveyor next to and parallel with the calcine-conveyor. This is layered on the surface of the charge by the distributer. This is to dissolve the silver.

Third. No. 2 solution goes on, following down after No. 1 solution. It is strengthened to 20% H_2SO_4, as has been already specified, by addition of 52% acid at the tank, and amounts in all to 150 tons.

Fourth. 100 tons of No. 2 solution of 1 to 1½% H_2SO_4 is added. Both the strengthened and the weaker No. 2 solutions drain to No. 1 tank, where it arrives containing

[1] The adjustments of this charging machinery have not been altogether attained, but no doubt can be. One is disposed to compare it with the Blaisdell sand-distributing and excavating apparatus.

[2] As No. 2 solution flows upon the leaching-tank, sulphuric acid of 52° B. is added to it from the 190-ton acid-tank in the building adjacent to the steel stack at the south end of the roaster-building. By this means the outflowing solution is brought up to 20% H_2SO_4. Since the acid of this solution is largely exhausted before it has sunk through the ore, there are no solutions high in acid going to any of the solution-tanks.

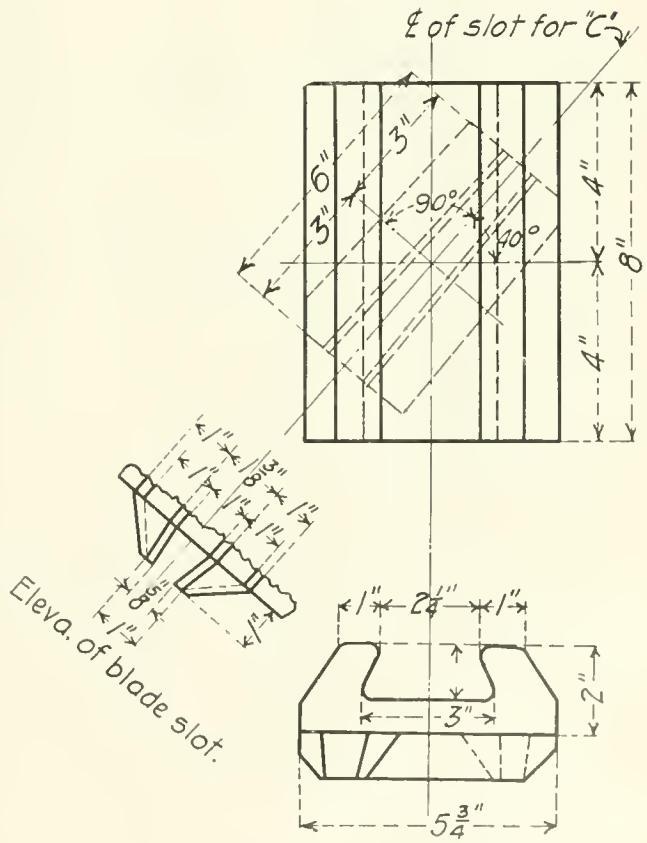

FIG. 11F.

DETAILS OF MCDOUGALL RABBLE.

5% H_2SO_4 and enough salt, picked up from the salt layer, to raise the solution content to 8% Nat'l. It is used as No. 1 solution on the next tank to be leached.

Fifth. Clear fresh water from the water-supply line is run on. This drains to the wash-water tanks, No. 4 or 5. This wash water, containing some acid, salt, and copper, is added to No. 1 solution, as needed, to supply the necessary wastage of that thrown away to get rid of basic salts and that carried off in the tailing.

The cycle of operations takes 120 hours, of which 8 hours is devoted to emptying the tank, 11 hours to filling, 101 hours to leaching.

There are three scrap-iron launders or vats having false perforated bottoms, each divided into three compartments by partitions. These are filled with scrap, much of it large, from the accumulating supply of the Washoe works. It is valued at $6 per ton. Choicer scrap, used at the copper precipitation plants at Butte can be bought for $8.50 per ton. The precipitate is washed off by a hose-jet from the scrap-iron surfaces, and, going to the bottom of the tank, is flushed into the settling-tank parallel with and adjoining the precipitating-launders. After draining, it is excavated by a clam-shell grab and loaded upon cars for final treatment.

For further particulars and a full description, see E. P. Mathewson's article in the *Engineering and Mining Journal* of April 24, 1915, to which the present article is to be regarded as supplementary.

The 100-Ton Acid Plant

This is intended to supply, not only the 2000-ton leaching plant at the Washoe works, but for meeting commercial demands; and it indicates that a serious attempt has been made to utilize the sulphur fume, now so abundantly escaping from the main stack of the smelter.

The plant manufactures its acid according to the standard lead-chamber process. In principle, the sulphur dioxide, arising from the roasting of pyrite, is immediately conducted, together with the excess air of roasting, and some nitric oxide, into a series of large leaden chambers in which it is continuously brought in contact with steam (or water-spray) and this nitric fume. The latter acts as a catalizer or go-between in transferring the oxygen of the air to the sulphur dioxide.[4]

To produce 100 tons of acid daily, some 85 tons of fine concentrate, containing 36% sulphur, is required. This is first dried in a Ruggles-Coles drier placed at the east end of the main roaster-building. The dried ore is withdrawn from the storage-hopper at the drier into a 50-ton hopper-bottom car, so designed that it may be closed by hinged lids or covers to prevent the possible escape of dust in the transfer to the acid plant, fully a mile away.

The roasting is performed in two Wedge furnaces 22½ ft. diam., having seven hearths. It was attempted at first to operate the furnaces with air-cooled arms and rabbles, but, owing to the high temperature developed in the roasting, this had to be given up, and water-cooling substituted. The roasted ore, still retaining 7.5% sulphur, is returned by car for reverberatory furnace treatment at the main works.

The roaster gases, containing some air and about 8% sulphur dioxide, pass through a dust catcher which is 32 ft. diam. by 14 ft. high, and settles out much of the dust.

In the so-called nitre plant or chamber are six boxes 2 by 2 by 4 ft. long, called 'nitre pots.' Here the sodium nitrate, decomposed by addition of sulphuric acid, gives off nitric acid fume, and leaves a residue of melted sodium sulphate, the latter being tapped from the boxes from time to time into overflow-pans just outside the nitre-chamber.

In plan, the Glover chamber is shown in Fig. 11 as containing clay pipes set vertically. As a matter of fact the space is filled with acid-proof tiles 12 by 18 by 1.5 in. thick. These are set on edge to form a checker-work for the downward passage of the gases. Distributed over this checker-work, trickle two mingled streams of acid, the chamber acid of 52° B. and the nitrous sulphuric acid from the Gay Lussac towers of 60° B. It is the nitrous fume from the latter acid that is taken up by the SO_2 gas, so that there is a recuperation of this expensive chemical.

The outflowing acid from the Glover tower enters a vat, marked 'acid tank,' cooled by water-cooled lead pipe-coils, the temperature by this means being reduced from 82 to 5°C.

From the Glover tower the gases are sucked through five cooling chambers, then driven by a fan in series through 18 cooling-chambers and 6 main chambers, all made of 6-lb. sheet-lead $\frac{1}{16}$ in. thick. One would naturally ask, why are there so many expensive cylindrical chambers provided between the main ones? It is for the more thorough mixing of the reacting gases as they pass alternately up and down. The gases enter the first main chamber at 95° C. (the boiling point of water at Anaconda) and escape at the end of the last one at 35 to 40°C. in summer, and at 15 to 20°C. in winter. The acid is a little weaker at the last chamber and circulates in a contrary direction from the gases. It issues at a concentration of 52° Baumé.

Lead-burning consists in fusing together lead sheets, using a blow-pipe flame of hydrogen gas and compressed air, with lead wire for solder upon the freshly-scraped surface of the joint. Easy as the work seems to be, it requires much skill. The easiest joints are those made with the sheets laid flat. With care, vertical joints can be made readily, but overhead ones are the most difficult. Each side of the main lead-chamber, 96 ft. long, was made of four sheets each 24 ft. wide by 36 ft. high. A sheet of this size was assembled on a platform from narrower sheets and burned together into one. The platform was hoisted to stand on edge and the top of the

[4]The gases, issuing from the main stack of the works, present similar conditions for making sulphuric acid, except that the sulphur dioxide is soon diluted and there is no catalizer present. Otherwise, especially in wet weather, we might expect it to rain a dilute solution of H_2SO_4 upon the place beneath.

sheet was turned over and nailed to the beam forming the top corner of the chamber. All the side-sheets being in place the final vertical joints were made. The flat top was then added. The framing of the sides and top are suspended from the roof-trusses, and the lower edges of the sides dip beneath the acid into a tray or shallow tank 2 ft. deep. This makes an air-tight seal, although the sides hang loose in the tray. Wooden posts bear against the sides to prevent bulging and the sides are secured to the posts by lead strips burned to the sheets. The end posts of the extreme main chambers have had to be reinforced by I-beams. In setting these, while the plant was in operation, one slipped from its sling, and its end tore a hole in a side sheet, causing the escape of a cloud of gas and driving away the working gang. Under the direction of the superintendent, however, the fan was stopped, the I-beam removed and the break covered by a sticking-plaster of building-paper painted with hot tar. Upon this was clapped a square of sheet-lead that was immediately burned into place.

From the last cooling-chamber the gases pass to the 21 Gay Lussac scrubbing-towers, where they meet the acid trickling downward through the hard-burned coke with which the towers are filled. The acid takes up the remaining fume of nitrous oxide to form nitrous vitriol. The gases escaping contain 96% of nitrogen and 4% of oxygen, the SO_2 having been absorbed. The towers are made of acid-proof tile laid in acid-proof cement. Some leakage occurs through the joints, so that the corroding acid reaches the adjoining framing. To avoid this it will be necessary to go back to the usual construction, using a sheet-lead shell. The coke-filling also accumulates lead sulphate and gradually crumbles. It will be replaced eventually by tile, as in the Glover tower.

The chambers stand 16 ft. above the ground-level, and this leaves room below for the six acid-tanks, and the so-called 'acid eggs,' a name derived from the earlier shape of these receptacles. There are eight of these marked 'blow cases,' each 4 ft. diam. by 21 ft. long. Into them is run acid from the acid-tanks. By compressed air the acid is raised to the top of the Glover or the Gay Lussac towers, or put into the tank-cars, by which it is sent away

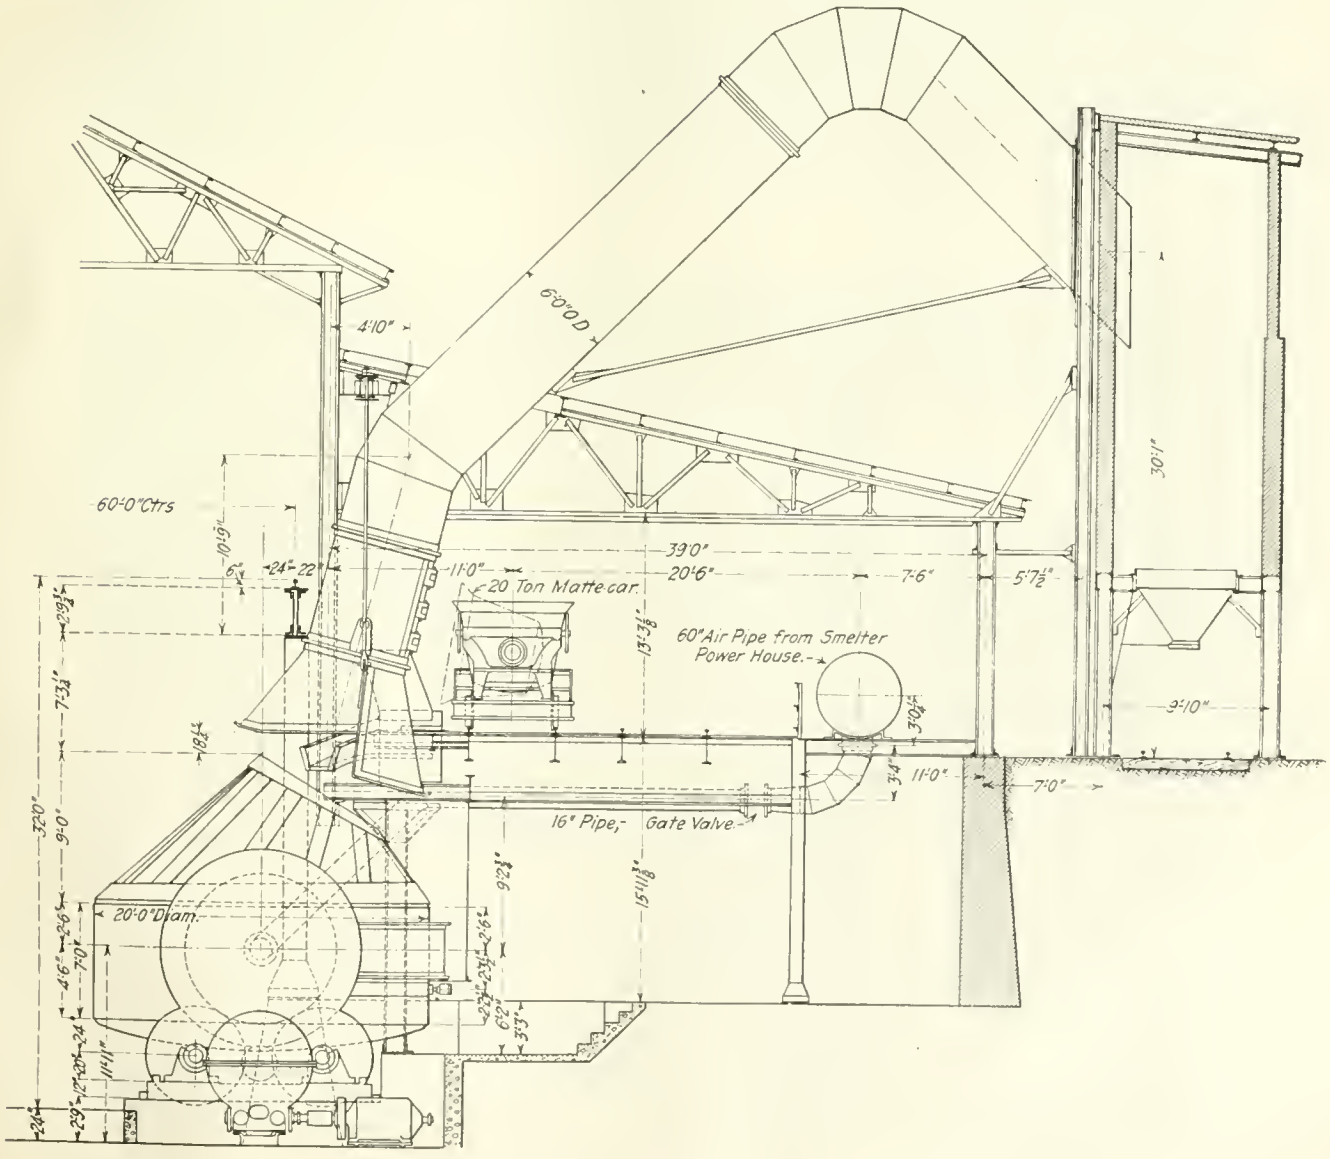

Fig. 12. Elevation of 20-ft. converter.

into commerce. There are no pumps or moving parts subject to acid action.

Details of the McDougall Roaster

The peripheral drop-holes of the even-numbered hearths have been doubled in length and recessed two inches into the exterior wall, thus increasing the diameter of the hearth by 6 in. and the effective roasting area by 6%.

The rabble arm and its appendages have been thus improved. Fig. 11*A* is a side elevation and end view of the Kelly arm, the end view showing the upturned edges of the arm upon which the flue-dust accumulates, thus protecting the arm against the heat. One arm of each hearth has a pad marked 'pad on *F* only,' over which is slipped a top rake, Fig. 11*E*. This rake in its travel breaks off any accumulation of flue-dust, which coming up through the drop-hole, tends to attach itself to the roof of the hearth. In Fig. 11*D* are seen the two solid cast-iron right and left-hand skewed rakes, marked *A* and *B*, by which the ore is moved to the periphery or to the centre of the hearths, as may be desired. In the case of a peripheral discharge, one outer blade is chosen, which is set to plow the ore inward from the walls into the drop-holes. In Fig. 11*E* is shown a rake with its blade without bevel. This is put in at any desired time and place for the purpose of scraping off any ore that has stuck to and accumulated on the hearth. Fig. 11*F* represents another kind of rake. It consists of a holder marked *D*, which, like the rakes *A* and *B* of Fig. 11*D*, is dove-tailed to slip over the arm, but carries on its lower part a tapered beveled slot, and in this slot fits a blade, Fig. 11*G*. If this blade becomes worn or broken, it can be easily removed from its holder and another blade substituted. The ordinary solid rake is much more difficult to replace.

The 20-ft. Converter

Fig. 12 gives the elevation of the 20-ft. Great Falls converter as installed in the converter building.

This converter is driven by a 100-hp. mill-motor, and can be completely revolved on its riding-rings. Outside one ring is set the spur driving-gear that meshes into the driving-pinion below.

Adjoining the elevated track, which carries the 20-ton matte-car, are two pouring-spouts, having movable launders, so that the flow of the matte may be properly directed into the mouth of the converter.

Air at 15-lb. pressure is admitted by a 5-ft. pipe from the smelter power-house. The air enters the converter through 31 independent tuyeres each of 1¾ in. diameter.

The hood leads off by a 6-ft. goose-neck to the large dust-chamber adjoining the converter-building.

There are three traveling cranes in the converter-house.

In operation these converters work more quietly than the smaller ones, there being but little material slopped out. The molten bath is most agitated at the back, that is above the tuyeres. The molten contents cascade toward the front, and sometimes send up jets that shoot above the mouth of the converter. The bath changes progressively from green-yellow to full yellow and the reverse. A reddish-yellow cast is also observable. On the bath, toward the front, appear darker colored spots apparently due to the beginning of formation of crusts.

Fig. 13 shows two converters in operation; the one in front blowing, and the other pouring. Fig. 14 illustrates the operation of the slag-casting machine, which is seen in the act of receiving slag from a ladle moved by a traveling crane. On the front cover of this issue the reader will see the Great Falls type of converter under construction in the smelter-yard.

The *Cornish Post & Mining News*, published at Camborne and Redruth, Cornwall, contains in a recent issue, beside a column of Michigan and Butte personals, a note on 'The Other Kind of Mining.' It states that: "the mining reports made by certain engineers after the War to Directors will be weird reading. Instead of dealing with the metallurgical content of the rocks there will be reference to a tunnel driven close to the enemy's trenches, strict secrecy being observed and no casualties from counter-mining. Instead of advising that payable ore has been struck, the engineer may advise that taking the angle of least resistance into account and the size of the charge, a satisfactory crater can be formed by the explosion and a general advance of troops rendered practicable. It must be a novel and extraordinary experience to carry on underground warfare. In Cornwall our miners have been known to proceed warily towards the abode of a subterranean enemy, but the enemy has been a passive resister, a huge body of water silently awaiting the blow of the pick that will release its pent up volume. By cautious prodding, the lake has been tapped and drained gently away. In other cases the water has been holed into unexpectedly as at Wheal Owles, where a score of miners lost their lives. But the mining engineer who is engaged in destructive mining at the front, commands a large body of human moles who dig as silently as possible through the earth until their gallery or galleries are underneath the trenches of the enemy. All the time they know that a similar body of miners is working toward their own trenches and machine-gun emplacements. It requires the highest kind of sustained courage to remain at a listening-post in a narrow tunnel day and night knowing that your enemy is gradually getting nearer, and that you may be blown up. No story of Jules Verne, Edgar Allen Poe, or H. G. Wells equals in living interest the facts of this underground warfare. Some explosions are only intended to shake up the ground without making a crater at surface; others are intended to blow the enemy and his works into fragments. Science, initiative, endurance and sustained courage are called for; and when the story of our tunneling corps in Belgium, France, and Gallipoli can be told, the public will be amazed at the ingenuity, the fortitude, and the efficiency of our colliers, our tin-miners and their intrepid leaders, some of whom have laid down their lives after exacting a heavy toll in dead from the enemy."

Antimony Veins at Bernice, Nevada

By Willard Mallery

Geography. The Bernice mining district on the western slope of the Clan Alpine range, Churchill county, Nevada, is 40 miles north-east from Wonder and 70 miles south-east of Lovelocks. The district is served by freight-team from Fallon, Nevada, a distance of 90 miles and a good day's drive by automobile. At present there are two producing mines: the Antimony King mine at Bernice, and the Lofthouse mine 5 miles south-west. The greatest local elevation is Grant's peak, 7500 ft., eight miles south-west of Bernice. From this point the western slope of the range descends rapidly to 4000 ft. and then gradually to the floor of Dixie valley, said to be 2800 ft. above sea-level, the lowest point in the State. Sedimentary rocks are well represented in the district, flanking the intrusive granite or monzonite that forms the crest of the range. The upturned edges of the tilted strata appear along the trend of the ranges. The predominating strike is north-west and south-east across the trend of the range, the dip being north-east.

Ore Occurrence. The lower slate member of the sedimentary series is the only formation important as a source of antimony. All the mines or prospects examined occur within this horizon. The rock is an indurated shale, weathering yellowish to reddish-brown in color. Highly developed cleavage in two directions at high angles to the bedding causes it upon weathering to break into small thin shingles and pencils. Igneous rocks are conspicuously absent within this horizon.

Stibnite, the sulphide of antimony, is the only ore of commercial importance. Cervantite, the yellow oxide of antimony, forms thin coatings on the stibnite at the surface and massive thicknesses, eight to ten inches, in the weathered sections of some deposits, but this mineral quickly gives place to stibnite below the surface. One low-grade deposit carrying disseminated stibnite in quartz was observed, showing yellow altered surface material for a depth of six feet.

Antimony occurrences throughout this district are closely associated with isolated limestone strata. At the Antimony King mine there are two of these strata averaging 8 ft. wide and 300 ft. apart. They have the same strike and dip as the enclosing slate, and their trend is marked by prominent outcrops. The most persistent stratum is traceable for three miles. This rock is a fine-grained silicious limestone, massive and bluish-gray. It contains small cubes of disseminated pyrite. Normally it weathers grayish-white, but in some sections for continuous distances of a quarter of a mile these croppings are stained yellow by antimony oxide. Numerous prospect-holes furnish unaltered exposures showing specks of stibnite through the mass of the rock, also thin sheets of crystalline stibnite in cleavage and joint planes, but these antimony-bearing limestones do not furnish ore in any commercial quantity, as so far noted.

Antimony King Vein. The Antimony King vein is a true fissure with quartz-filling. It cuts the slate at nearly right angles and intersects the two limestone strata. It can be traced on the surface for 900 ft.; strike N 10° E, dip 50° W. The quartz-filling is from 4 inches to 4 feet wide, any portion of which may be replaced by solid stibnite. Both walls have a parting of black slaty gouge. The slate wall-rock is altered and carries disseminated cubical pyrite. Sphalerite is the only associate of the stibnite in the vein itself; it occurs but sparingly and at wide intervals.

This vein is regarded as remarkably persistent for an antimony deposit. The best ore-shoots occur south of the intersection of the vein with the southern limestone stratum. Here the lower drift has opened up the vein continuously for a distance of 200 ft. to a depth of 100 ft. A faulted segment of the limestone strikes nearly parallel with the vein at this intersection, and for a distance of 70 ft. this segment has become incorporated into the lode, forming a 'lime spur' lying next the hanging wall. The best orebodies occur in the quartz under this lime spur, where solid stibnite in widths up to 2 ft. has been discovered and mixed massive stibnite and quartz in widths up to 4 ft. This 'spur' feathers out on the south strike of the vein and the ore becomes less massive in character, showing a banded structure of alternate stibnite and quartz. Northward through the slate the vein, though small, continues with occasional good shoots of ore until it intersects the northern limestone stratum, beyond which it is apparently barren.

A genetic relation between the limestone and the orebodies is strikingly shown in the vein described, and is apparent throughout the district. The Lofthouse mine, six miles south of Bernice, is noteworthy in this respect. The vein is a fissure with quartz-filling and has the same direction of strike and dip as the Antimony King. The limestone stratum associated with it is the only one in an immense thickness of enclosing slate. In this mine the ore is less massive, occurring in fibrous and needle-like forms. Another illustration is furnished by a prospect a mile north of Bernice. Here an erratic quartz stringer, six inches wide, originates in the slate and intersects nearly at right angles a limestone stratum 10 ft. wide. On both sides of the lime the quartz is barren, but where it passes through the lime it widens to 8 inches and nearly all the quartz gives place to coarse fibrous stibnite.

In conclusion, the antimony deposits of merit or promise are essentially quartz-filled veins in slate, but deposits of importance have been found only where such veins are associated with silicious limestone.

Arizona has an area of 113,020 square miles, which is nearly twice that of Michigan. Its population of a quarter of a million is about that of Denver. Arizona's output of gold, silver, copper, lead, and zinc in 1915 was $88,551,000.

Geology of the Cottonwood Districts

By L. O. Howard

Introduction. The Cottonwood districts are situated in the central portion of the Wasatch range, which overlooks Salt Lake City on the east, and cover the upper portions of two east-west canyons, Big Cottonwood and Little Cottonwood, the divide marking the boundary between the two districts. The Park City district joins Big Cottonwood on the north-east, and the mineral zone extends from Park City through the Cottonwoods into American Fork canyon, which heads over the divide south of Little Cottonwood. The mouth of Big Cottonwood canyon is ten miles south and five miles east of Salt Lake City. Little Cottonwood is three miles south of Big Cottonwood. The principal properties in the two districts cover an area seven by six miles at the widest part. The principal town is Alta, in Little Cottonwood, 11 miles up the canyon. It is reached by stage from Sandy, on a branch of the San Pedro, Los Angeles & Salt Lake railroad. The trip up Big Cottonwood is made by automobile from Salt Lake in two hours, and most of the properties can be reached by this means. Ore and supplies are transported in Big Cottonwood by wagon, the ore being hauled either to the smelter or to the railroad at Murray. A spur runs from Sandy up Little Cottonwood to Wasatch, 2½ miles above the canyon entrance. An aerial tramway is operated in the summer months to transport Little Cottonwood ore to Tanner's Flat, leaving a gap between that point and the railroad of 3½ miles, over which ore must be hauled in wagons. The expense of the necessary snow-sheds and the danger from slides makes a railroad up the canyon to the mines an uncertain enterprise at this time. It is probable that a new aerial tramway will be the ultimate solution of this problem.

The district has had a regular but small output since 1867, having produced in that period $20,652,910.[1] Last summer marked intensive development, and a largely increased production is anticipated for 1916..

Topography. The region is one of high relief. The Wasatch range extends northerly and southerly for 200 miles. Its western border is marked by a steep fault-escarpment overlooking the Salt Lake valley. The crest of the range is near this western border, the slope eastward being long and less steep. The main divide lies from one to six miles east of the crest. The range is cut by many east and west canyons, with deep dissection and steep walls in the lower portions. Big and Little Cottonwood, especially the upper portions, are much marked by glaciation, indicated by rounded hills, U-shaped valleys, hanging lakes, and moraines. Abrupt cliffs terminate both canyons. Alta and Brighton have elevations of 8700 ft. The surrounding ridges rise to above 10,000 ft. These conditions make adits the logical means of development.

Stratigraphy. The following notes on the sequence of the formations are based on work done in 1912 by F. F. Hintze, Jr., published in the annals of the New York Academy of Sciences,[2] checked as to part of the section by my personal observations.

The sediments exposed range from the Archean to the Jurassic. Misunderstandings have arisen from a too close study of the formations about the more productive mines on the Alta side, and the difficulty of mapping the strata there without previous study of the sequence exhibited in Big Cottonwood. The geologic section includes great thicknesses of shales, quartzites, and limestones, from Algonkian to Jurassic, lying unconformably upon Archean schists and gneisses exposed near the mouth of Big Cottonwood. The great Cottonwood quartzite and slate series, variously estimated at 1000 to 6000 ft. in thickness, lies at the base. Unconformably overlying it are 700 ft. of Lower Cambrian quartzite and 150 ft. of Middle and Lower Cambrian shale, a dark, sandy, micaceous, thin-bedded shale, which in turn underlies the ore-bearing limestone of the Ordovician. This shale is found in the canyon below the Maxfield mine, near the head of South Fork and near Superior gulch in Little Cottonwood. The Ordovician limestone, exposed and mined in the Maxfield, and known locally as the Maxfield formation, is found on the top of Kessler's peak, at the south end of Reade & Benson's ridge, and southward in Little Cottonwood. The contact of the Alta shale and the Maxfield limestone is one of the markers in the district, and is the lower boundary of the ore-zone so far developed. The Maxfield formation, consisting of interbedded limestone and shales, is of a characteristic wormy appearance and light-gray to white. In it are found the ores of the western mines, the Maxfield, Cardiff, Fuller, Sells, and those north of Alta.

Overlying the Ordovician unconformably is nearly 1500 ft. of fossiliferous Devonian limestone, also productive. Next in the series are the limestones and shales of the Mississippian, the Reade formation, nearly 1000 ft. thick. The lowest member is a massive bluish limestone, the middle a thin-bedded sandstone and shale, overlain by a fossiliferous blue limestone. The lowest member is exposed at the north end of Reade & Benson ridge, between South Fork and Day's Fork. A great unconformity exists between the Mississippian and the Lower Pennsylvanian, the latter represented by the Weber quartzite, composed of an even-textured fine-

[1] Butler, Loughlin, and Heikes; Bull. 620-I, U. S. G. S., p. 194, 1915.

[2] Vol. XXIII, pp. 85-143, 1912.

grained rock. It is exposed near the Government forestry station in the upper part of Big Cottonwood canyon. Above it lies the Park City formation, which has been so productive of bonanza ore in the adjoining district. As deposited on the north side of the canyon it includes several hundred feet of limestone, with intercalated shale and quartzite. It has not been of great economic importance in the Cottonwood district.

Next above is the Woodside shale, dark-red, fine-grained, and carrying no ore. It is succeeded by the Triassic Thaynes formation, in which occurs the ore of the Scottish Chief mine on Scott Hill, on the Park City divide. As exposed on the north side of Big Cottonwood, it consists of 450 ft. of intercalated sandstones, limestones, and shales, with sandstone predominating in the lowest member, separated from the more limey beds above by 115 ft. of red shale. The upper 630 ft. is predominantly limestone. The Ankareh shale, which overlies the Thaynes, is exposed on the divide. It consists of 1100 ft. of red shale with some beds of coarse gray sandstone and a few beds of limestone. Just over the divide and along part of the ridge is the highest formation in the district, the Nugget sandstone.

Igneous Rocks. Three large masses outcrop. The geologists of the Fortieth Parallel survey mapped these as Archean, on which they supposed the sedimentary series was deposited. Geikie,[3] Emmons,[4] Boutwell,[5] and Hintze[6] are in agreement as to their intrusive character. Near the mouth of Little Cottonwood is a great mass of porphyritic granite extending nearly to Superior gulch, and in contact with the Cottonwood quartzites and shales along the divide between the canyons. This contact crosses Little Cottonwood at Hawley's Flat, about 1½ miles west of Alta. The more basic granodiorite outcropping near the centre of Alta extends under the amphitheatre in the south fork of Little Cottonwood, into Big Cottonwood near Twin Lakes, on the Lake Catherine pass, and forms the western wall of the head of the canyon, composing the ridge between Brighton and Solitude gulch. It extends also southeast to the head of Snake creek. Still farther east is a third mass, the quartz-diorite forming Clayton peak, and appearing on the walls at the south head of Big Cottonwood under Pioneer peak, and north-east in the Park City district.

Although no evidence has been brought forward by other investigators to connect the Alta and Clayton Peak masses, and Butler and Loughlin give no reasons for their opinion, the latter map the two as one mass and call it all quartz-diorite, reserving the name granodiorite for the Little Cottonwood granite. This results in an unfortunate confusion of terms. When the more recent writers decided to change the classification of these rocks contrary to all evidence and the previous report of Boutwell, it would have carried more weight had they given their reasons for the change. Hintze speaks of the three separate masses, granite, granodiorite, and quartz-diorite, and notes the absence of surface connection between them, while calling attention to the probability of their being differentiations of the same magma. Recently, in making examinations near the head of Big Cottonwood, I had occasion to prepare thin sections from samples taken from that part of the Alta mass which forms the ridge between Brighton and Solitude gulch, exposed on the west side in an old tunnel. This is the portion of the mass to which Boutwell refers when he says: "The Alta mass has made its way up through Paleozoic sediments overlying the Cambrian at the head of the canyon (Little Cottonwood), cutting across Carboniferous limestone, which it has metamorphosed highly, and extends eastward to form the western wall about the head of Big Cottonwood canyon, probably inducing the formation in the abutting truncated limestone of contact metamorphic minerals and ore-deposits."[7] Examination of these thin sections gave conclusive evidence of the character of the rock and agrees with the statements of Boutwell and Hintze. From these masses, dikes and sills have penetrated the surrounding sediments, metamorphosing them highly, and exerting a great influence on the formation of ore deposits.

Structure. The intrusive masses have domed the sediments, which dip away from the intrusions on all sides, generally at angles of 35° to 45°, with local variations from this dip. The western half of this dome has been cut off by the great Wasatch fault, and has been depressed to form the floor of the Salt Lake valley. In a particular zone the sediments have been much folded and faulted, the result probably of a great over-thrust from east to west. This is illustrated in the accompanying section from Alta in Little Cottonwood north-west to Argenta in Big Cottonwood, east of the Maxfield mine. This section is taken from Hintze. Along the ridge between Big and Little Cottonwood east from Superior gulch, the beds dip about 45° to the north-east and appear in the following sequence: Brigham quartzite, Alta shale, Maxfield limestone, Benson limestone, Cottonwood quartzites and shales, Brigham quartzite, Alta shale, Maxfield limestone, Benson limestone, Reade formation, etc. This duplication of beds has been thoroughly proved. As shown by the section from Alta to Argenta, its only effect on the north side of Big Cottonwood is to duplicate a portion of the Brigham quartzite. Within this zone of over-thrusting there is much crumpling of the beds and many minor faults. The line of the over-thrust can be traced from the south side of Big Cottonwood up South Fork, down Superior gulch, crossing Little Cottonwood, up Peruvian gulch into the head of American Fork canyon at Min-

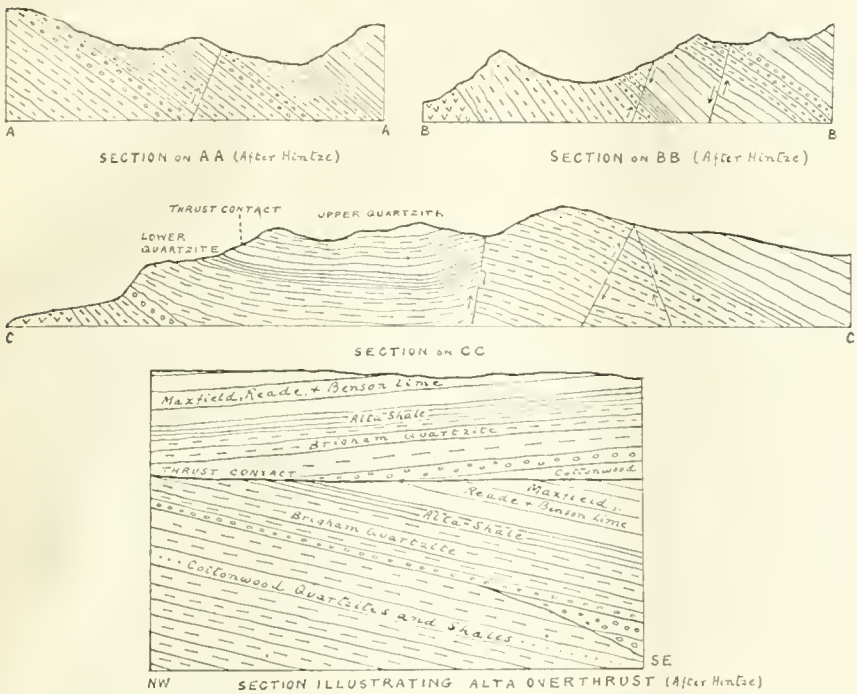
[7]*Op. cit.*, p. 67.

eral Flat. Its age is believed to be contemporaneous with the first disturbances in the region and to precede the intrusions.

There are two systems of faults, a NW-SE system and a NE-SW system, the origin of which is not clear, and is variously explained. They are considered by Hintze[8] to be strike-and-dip faults. He states that the NE system was the earliest and that the NW system occurred after mineralization, since faults of this system displace the ore. Butler and Loughlin[9] believe that both systems were the result of the intrusions, calling attention to their being radial to and concentric with these intrusions. They consider the Superior fault to be a reverse fault, concentric with the Alta mass, and not necessarily much later. The fault at the south end of Reade & Benson ridge they consider in the same class.

At the head of Silver Fork, just north of Alta, is a fault that Hintze estimates to have a displacement of 500 to 600 ft.; this he is unable to classify as normal or reverse. He inclines to the view that the block between this fault and the Superior fault has gone down farther on the west than the east, and that the minor faults between these two were a part of the same disturbance.

As the most pronounced fault in the district, except the Alta over-thrust, the Superior fault deserves brief description. Its trace is observable from below the Cardiff mine in the South Fork of Big Cottonwood, over the ridge, and down Superior gulch in Little Cottonwood, the trend being nearly north and south. Appearances in South Fork indicated normal faulting, but more pronounced evidence in Superior gulch shows that it is a reverse fault, with nearly vertical displacement. This interpretation shows the Cardiff to be in the lower limestone, and that there is a deeper limestone on Reade & Benson ridge than was at first supposed. Exact measurements have been difficult. The fault-trace dies out in crossing Big Cottonwood, although in line with the fault-plane the western side of these same beds has evidently dropped on the north side of Big Cottonwood, indicating, until further evidence is available, that the fault is possibly pivotal, with its fulcrum between the Cardiff and the mouth of South Fork.[10] Butler and Loughlin note but few local faults that are definitely later than the ore deposition, although there is reason to believe that many of the minor faults between Superior and Silver Fork, and these two great faults also, have displaced the ore-bearing fissures. A consensus of opinion prevails that the great Wasatch fault and its accompanying minor faults were much later than the ore deposition, and that the period of subsequent readjustment covered a long time.



SECTIONS ACROSS THE COTTONWOOD DISTRICT. (See map on page 561.)

There is a tendency among some of the operators to regard each of the north-south gulches leading into Big Cottonwood, namely, South Fork, Day's Fork, Silver Fork, Honeycomb gulch, and Solitude gulch, as lines of faulting. They have no definite proof to offer, and are doubtless letting generalities lead them into unsound conclusions, depending rather on 'hunches' than on exact observation and critical reasoning.

It is obvious that much detail work must be done before the different systems of faulting can be satisfactorily classified, and it is equally obvious that this work will not be done until the Government can be induced to order a thorough study of the region. There is no district in the State where the need is more urgent. Underground development now being done should clarify the geologic structure, especially in the north-eastern portion of the Big Cottonwood district, where both main systems of fissuring appear to be well mineralized.

Ore Deposits. These may be placed in three classes, vein or fissure deposits, contact-metamorphic deposits, and bedded deposits. The division between these types is not clear-cut, all evidently having been formed during the same periods of mineralization, and being genetically connected with the intrusive stocks of quartz-diorite and grano-diorite, or their off-shoots. In the vein type there is invariably some replacement of the walls, and where favorable limestone beds are intersected by the fissures, replacement-deposits are formed. Contact deposits are found especially along the north side of the Alta grano-diorite, the limestone being highly metamorphosed in the vicinity of this stock, with the development of typical contact minerals, such as diopside, garnet, magnetite, pyrite, and in the Mountain Lake mine the boron

[8] *Op. cit.*, p. 137.

[9] *Op. cit.*, p. 179-182.

[10] Hintze, p. 139.

mineral, ludwigite. At the surface these zones often contain from 1 to 2% copper with some silver and gold, the oxidized minerals surrounding a core of sulphide. The metamorphosis is most marked in zones parallel to grano-diorite dikes, and at varying distances from them. The white limestones appear to be the more highly metamorphosed, some thin sections showing complete alteration to diopside. Not much development has been undertaken on the typical contact deposits.

The vein deposits occur in rocks of varying characteristics, in the Cambrian shales and quartzites of the Toledo and Cardiff, the Ordovician and Devonian limestones of the Emma and City Rocks, and the Thaynes of the Scottish Chief. For a detailed description of these veins I refer the reader to pages 202 to 208 of the Survey bulletin by Butler and Loughlin. The outcrops are in places soft ochre-stained limestone members, in others hard, porous, rusty, and silicified, changing with moderate depth to a soft earthy hydroxide of iron, containing chimneys rich in lead and silver oxidation products. The width of the veins varies from 1 to 20 ft., with an average of 3 ft. They dip at high angles, usually to the north-west, from 55° to vertical. The wall-rock in the Fuller, Cardiff and Branberg is quartzite; in the City Rocks, Butte, Oregon and other veins to the east it is white limestone, the vein tending to pinch in the hard blue limestone. The vein-stone of the Fuller, City Rocks, Savage, Montezuma, Butte, Oregon, South Hecla, and Albion, has been soft earthy hydroxide of iron with cerrusite, anglesite, manganese dioxide and argentite. It occurred mainly in chimneys from 50 to 200 ft. long, pitching with the strike of the veins, and separated from each other by about equal amounts of barren vein-matter. Chlorides are invariably absent. Wulfenite is a common mineral.[11] The oxidized ore persisted below water-level, where development ceased. Where opened on some of the lower levels, the ore in these veins has been found to be 6 to 18 inches wide, consisting of a mixture of chalcopyrite, galena, sphalerite, and tetrahedrite in a gangue of quartz. Molybdenite is common. While the oxidized ore has been usually of a shipping grade, the sulphide ore of the lower levels more often requires milling.

The bedded deposits have proved the largest and richest. They are found at the intersection of mineralized fissures with certain favorable limestone beds, and where found in quartzites and shales, are usually in limestone beds. The white porous limestone is the most favorable for these deposits also. The deposits are generally lenticular, with strike and dip conforming with that of the formation, and the longest dimension along the dip. They are often 200 ft. long, and extend 100 to 500 ft. in depth. Their thickness varies from 1 to 30 ft., but averages about 10. They are usually connected by narrow seams of ochreous material or pipes of mineral. In the limestone the ore has the same characteristics as in the fissure deposits.

In some of the mines, notably Alta Consolidated, it has been noted that where the ore is in the shale, it appears as galena, sphalerite, pyrite, and tetrahedrite. Ore deposits of the bedded type have been found in the Emma, Flagstaff, Columbus, Alta Con., Prince of Wales, Cardiff, Maxfield, Reade & Benson, and Carbonate. In the Vallejo and North Star the form taken was that of pipes and shoots.

Ore has been found in fissures in the Brigham quartzite in the over-thrust zone. Little attention has been given to prospecting the quartzite below the lowest limestone beds. A narrow vein following the bedding of the quartzite is now being explored in the Logger ground, in the north-western portion of the district, below the limestone series. Bunches and lenses of oxidized lead and silver ore in a clay gangue, and streaks of high-grade chalcocite have been found.

Still farther west in the Algonkian quartzite and slate series, chalcopyrite and galena are intimately mixed with barite and quartz in porphyry, but no development has been done on these narrow stringers.

Relation to Park City District. There has been talk about the Cottonwood mines being in the same formation as those of Park City. A glance at the geological section shows thousands of feet geologically between the Ordovician and Devonian of Cottonwood and the lowest productive formation of Park City, the Weber quartzite. The orebodies of Park City are genetically related to the Clayton Peak stock of quartz-diorite, whereas those of Cottonwood are more intimately related to the Alta stock of grano-diorite. No commercial deposits have been developed in association with the Little Cottonwood granite, although much low-grade molybdenite is found in connection with it in Little Cottonwood, near White Pine and Red Pine gulches.

Referring again to Butler and Loughlin's designation of the Alta mass as quartz-diorite and the Little Cottonwood granite as grano-diorite, the following quotation distorts the actual conditions. They say: "Around and closely associated with the Little Cottonwood stock of grano-diorite, intruded into the pre-Cambrian and early Cambrian rocks, few if any deposits of commercial importance have been developed, while most of the important deposits of the belt are associated with the Clayton Peak stock of quartz-diorite."[12] This statement becomes true only when for "grano-diorite," we substitute "granite," and for "Clayton Peak stock of quartz-diorite," we say "Alta stock of grano-diorite."

One other statement of Butler and Loughlin is worthy of note here. They say: "A study of the ore deposits of the State indicates that as a general rule the greatest mineralization occurs toward the top of intrusive stocks or in the adjacent sedimentary formations at a corresponding horizon, and therefore it is not probable that the mineralization in the Cottonwood-American Fork area was so extensive as that in the Park City district."[13] However, this should not be a cause for much

[11] Hess, F. L., 'Wulfenite at Alta, Utah.' U. S. G. S. Bull. 340, p. 238, 1906.

[12] *Op. cit.*, p. 225.

[13] *Op. cit.*, p. 226.

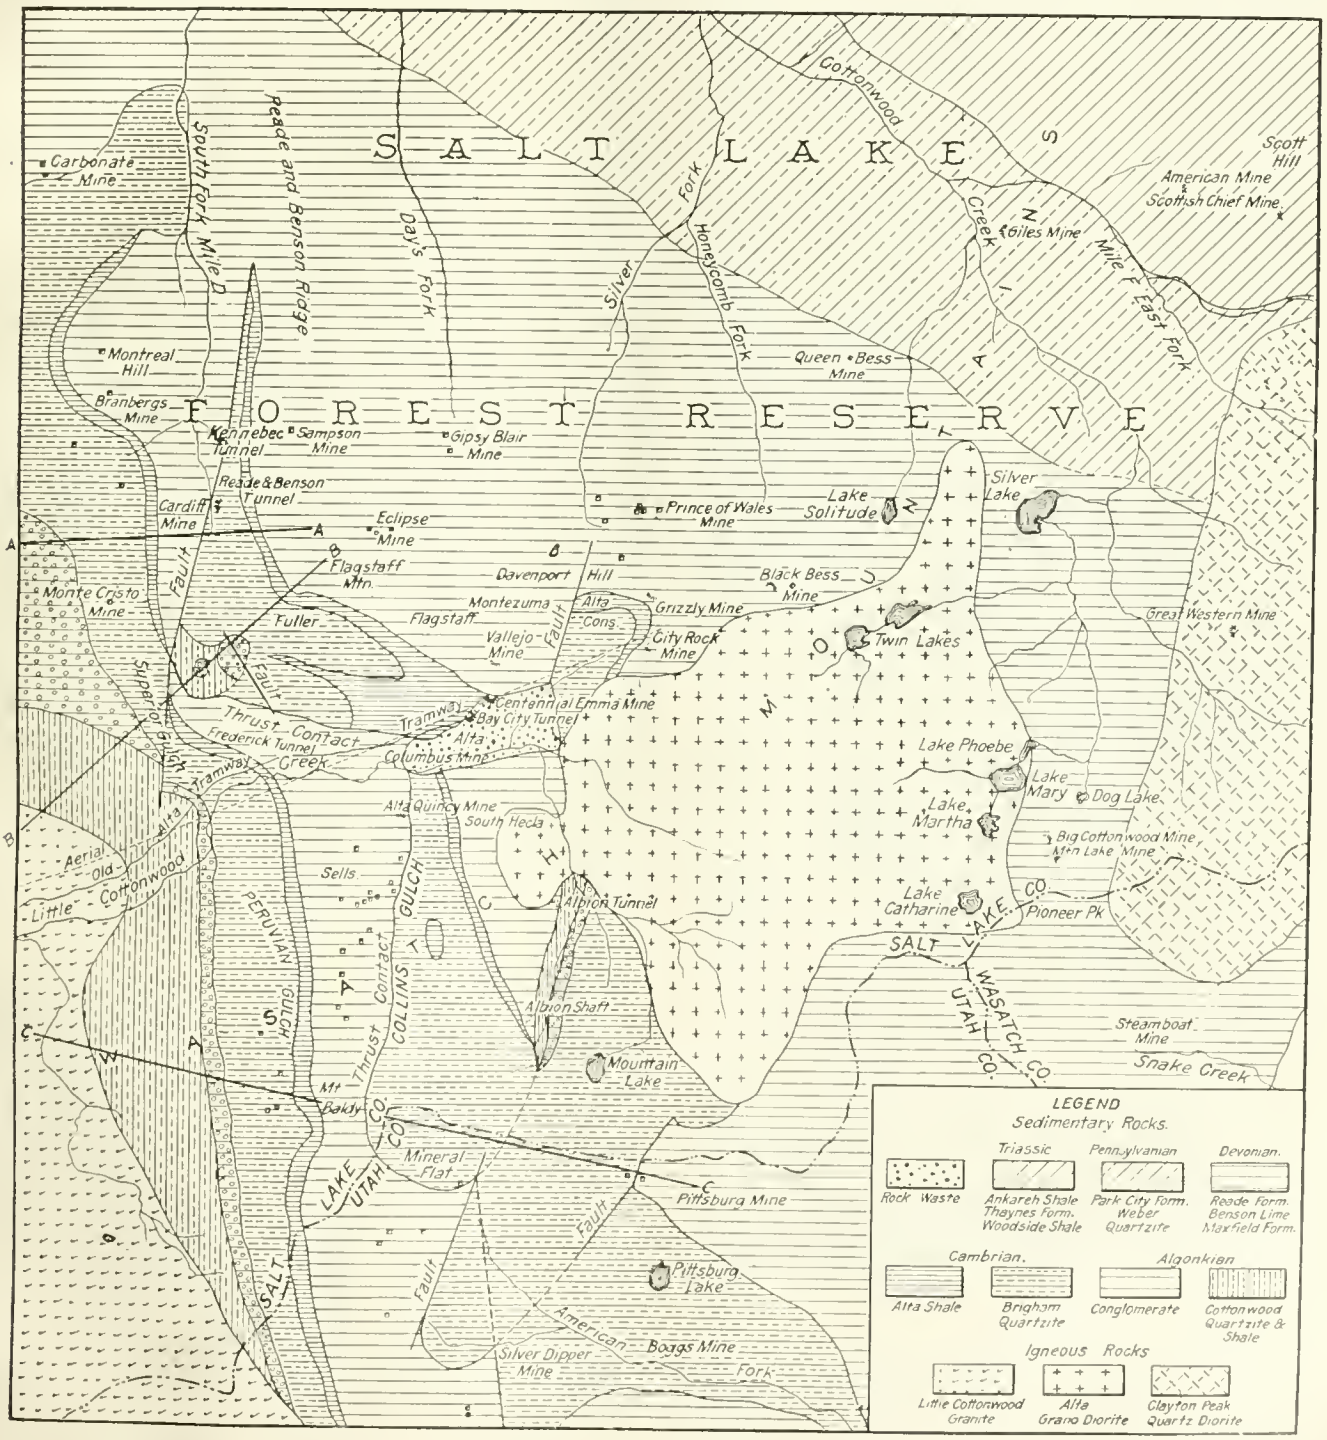
apprehension on the part of the Cottonwood operators, for the mineralization may well be less than in the 'bonanza' Park City district, and yet justify and reward intelligent efforts to open profitable mines.

Summary. 1. The sedimentary series of the Cottonwood districts consists of interbedded quartzites, limestones, and shales, ranging from Archean to Jurassic, of which the Lower Cambrian quartzites and shales, and the Ordovician and Devonian limestones have been the most productive.

2. Beds from the Algonkian through the Devonian have been duplicated along the divide between the two districts by a great over-thrust, probably of the same age as the main Wasatch folds, late Cretaceous.

3. Igneous activity is represented by three intrusive stocks of granite, grano-diorite, and quartz-diorite, which have domed the sediments, of which those associated with the grano-diorite stock have been the loci of ore deposition.

4. Coincident with the intrusions, radial and concentric fissures and dikes were formed, along which subsequent mineralization deposited the primary ores. The NE-SW system in the central zone appears to be more mineralized than the NW-SE system. Oxidation has



GEOLOGIC MAP OF BIG AND LITTLE COTTONWOOD MINING DISTRICTS, UTAH.

converted the primary galena, chalcopyrite, sphalerite, and tetrahedrite into high-grade 'carbonate' ores.

5. Later faulting in a north-south direction caused the drop of the large block between Superior gulch and Silver Fork, with the production of a complicated series of minor faults, some of which cut off the ore-fissures and make development difficult. This faulting was probably contemporaneous with the great Wasatch fault, which dropped the western half of the dome below the floor of Salt Lake valley. The existence of a pivotal fault, with its fulcrum between the Cardiff and the mouth of South Fork, is indicated.

6. Ore deposits are of three types, fissure, bedded, and contact-metamorphic, and appear principally in certain limestone beds of the Brigham, Maxfield, and Benson formations. The white porous limestone seems to be most favorable to ore. The three types grade into each other, and are genetically related to the intrusion of the grano-diorite.

7. The fissure deposits occur in Cambrian shales and quartzites, Ordovician and Devonian limestones, and to a limited extent in the Triassic Thaynes formation which is more closely related to the Park City district. The ore occurs in chimneys having a high pitch and dip, usually about 3 ft. thick.

8. The bedded deposits are in the form of lenticular masses of little thickness, but having considerable length and depth, in certain favorable limestone beds, at contacts of the limestone with other beds, and at the intersection of fissures with these beds and contacts.

9. Contact deposits have been formed in certain limestone beds that have been highly metamorphosed by the intrusives, the typical contact minerals, diopside, garnet, magnetite, pyrite and ludwigite being prominent.

10. The past production has come mainly from the soft beds containing the products of oxidation of galena, argentite, tetrahedrite, chalcopyrite, and various sulph-arsenides and sulph-antimonides. Chlorides are generally absent. Wulfenite is common. This ore has assayed above 100 oz. silver and 38% lead. The sulphides are found more often in the quartzites and shales, and are not so rich. With these molybdenite is common.

11. The ore deposits do not occur in the same formation as those of Park City, but are several horizons lower, and it is noted that the mineralization in the Cottonwoods is not as extensive as in the Park City district.

COLORADO'S output of gold, silver, lead, zinc, and copper in 1915 was $43,100,000, compared with $33,460,126 in 1914. Colorado's area of 103,925 square miles is over twice that of Pennsylvania; its population of over 800,000 is greater than that of Montana and Arizona combined, though its metal output is much less.

LATIN-AMERICAN COUNTRIES have an area three times that of the United States, and a population equal to that of this country. The foreign trade of Latin-America in 1913 was $2,800,000,000; that of the United States was $4,200,000,000.

Mineral Production of Rhodesia

The following table gives the output for 1915:

	Quantity	Value
Gold, ounces	915,029.36	£3,823,168
Silver, ounces	185,231.83	17,146
Copper, tons	3,511.52	217,643
Lead, tons	27.77	557
Chrome iron, tons	60,580.75	204,910
Asbestos, tons	2,010.11	32,190
Coal, tons	309,763.00	123,192
Diamonds, carats	272.05	1,016
Copper matte, tons	9.50	285
Ironstone, tons	9,622.13	1,699
Total		£4,421,806

In 1914 the grand total value from all sources was £3,882,996. The increase in value is therefore over £500,000, of which about half is due to the gold yield.

PUMPING EQUIPMENT at the Old Dominion mine, Globe, Arizona, has both steam and electric units, the latter for the deeper levels. Steam pumps on the 1000, 1200, and 1400-ft. levels lift direct to water-storage tanks on surface and to a drain tunnel; electric pumps on the 1400, 1600, and 1800-ft. levels lift the water to the main station on the 1200-ft. level to be relayed to surface. Four of the steam pumps are Prescott triple-expansion duplex type; and four are Nordberg triple-expansion fly-wheel type. The steam pressure at the pumps is 134 lb. The triple-expansion fly-wheel pumps, which are used in normal times, consume 18 to 18.2 lb. of steam per water horse-power. The electric pumps on the lower levels include an Aldrich vertical quintuplex single-reduction plunger pump with 150 hp. A.C. motor; this lifts 900 gal. per minute a height of 400 ft. In the same station with the quintuplex pump are three vertical, triplex, double-reduction pumps, run by D.C.; these also lift 400 ft., the largest having a capacity of 470 gal. per minute, the smallest 180 gal. Below are two horizontal, quintuplex, Aldrich pumps, each with a 250 hp. A.C. motor; pumping 600 ft., these have a capacity of 1100 gal. per minute each.

BOLIVIA, although shut off from the rest of the world by other countries, is reached by three excellent railroads. One extends inland from the port of Mollendo, Peru, and two from the ports of Arica and Antofagasta in Chile. From Arica to La Paz, Bolivia's mountain capital, is 30 hours by train. La Paz, a city of 70,000 people, has street-cars, electric lights, telephones, and modern buildings. The south-western part of Bolivia, where are the important mines, is a barren plateau. The northern and eastern parts of the country are vast rolling lands and prairies drained by branches of great rivers that empty into the Atlantic. Of the South American nations, Bolivia has the highest proportion of pure Indian population. Mining is the chief industry. In 1913, the United States furnished 7½% of Bolivia's imports.

Rapid Method for Tungsten

By M. L. Hartmann

The accurate methods* for the determination of tungstic oxide in ores are longer and more laborious than is desirable for control work in mining operations. The great activity in the production of tungsten ores has created a demand for a rapid method accurate enough for the purpose stated. The following schemes, modified from the more accurate *aqua regia* method have been used successfully.

Treat one gram of the very finely ground ore with about 50 cc. *aqua regia* in a 4-oz. flask. Heat the solution, but do not boil; shake the flask frequently. When the solution is evaporated to about 10 cc. and no black particles remain undissolved, dilute with 50 cc. hot water and allow to stand for half an hour. Filter through an ashless paper, and wash the residue thoroughly with hot water slightly acidulated with hydrochloric acid. Ignite the paper with the residue of silica and tungstic acid in a weighed platinum crucible with free access of air. Fill the crucible with hydrofluoric acid, evaporate to dryness, ignite and weigh as tungstic oxide. The final product should be bright yellow in color.

With certain ores there is some difficulty in getting all the material into solution by this method. In this case fusion of the sample in sodium carbonate by the longer and more accurate method is the only real solution of the difficulty. With large quantities of tungstic oxide, there is danger of injury to the platinum crucible by alloying it with tungsten produced by reduction by means of the burning carbon of the filter-paper. It is better to burn the paper on a platinum wire, and allow the ash to fall into the platinum crucible. If the residue contains a large amount of silica, the evaporation with hydrofluoric acid should be repeated.

It is frequently necessary to make the determination when a platinum crucible is not available. Without platinum ware it is not possible to make the evaporation with hydrofluoric acid to remove the silica. Under these circumstances the following method can be used:

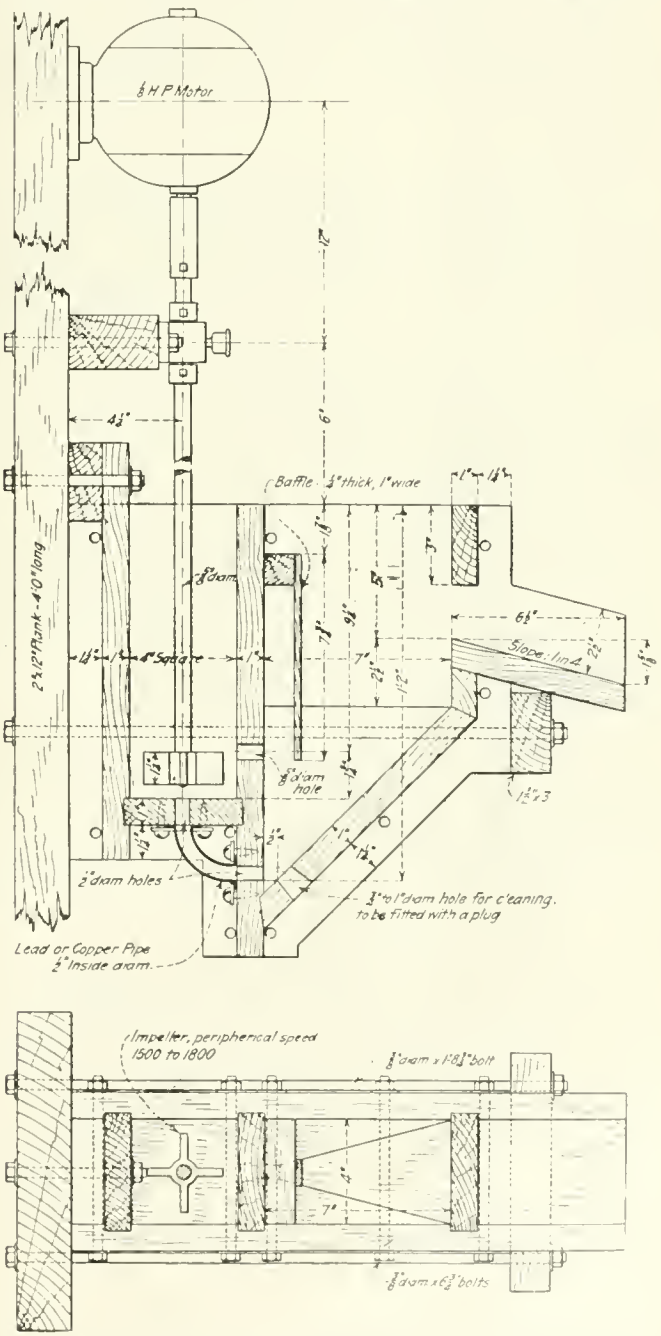
Decompose one gram of the ore with *aqua regia* as described above. Add 50 cc. hot water, and let stand for half an hour. Decant the solution through a filter-paper, and wash the residue in the flask several times by decantation, using about 50 cc. hot water slightly acidulated with hydrochloric acid. Keep back in the flask as much of the residue as possible. Add about 20 cc. ammonium hydroxide solution (200 cc. strong ammonia, with 1000 cc. water and 10 cc. concentrated hydrochloric acid). When the yellow tungstic acid is all dissolved, transfer the residue by means of the ammonium hydroxide solution to the filter-paper, and wash thoroughly with water. This residue should be pure white (silica). Evaporate the solution to dryness in a weighed porcelain crucible, ignite gently to drive off the ammonium salts, and finally heat strongly to constant weight. The tungstic oxide thus obtained will be contaminated with a small amount of silica, therefore the results are usually a little high by this method.

In either case it must be borne in mind that at best these methods are only approximate and that there are several chances of error. They are useful only as rapid methods for mine-control work.

*See *Pahasapa Quarterly*, South Dakota State School of Mines, February 1916.

A Flotation Machine

Herewith is a drawing of the flotation apparatus used at the mine of the Suan Concession, in Korea, a company under progressive American management. It was employed to check small-scale tests and for removing chalcopyrite from scheelite. The capacity is 100 pounds of crushed ore per hour. The total cost, including motor, is under $50.



CONCENTRATES

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

FLUE-DUST from the Copper Queen blast-furnaces amounts to 4.29% of the charge smelted.

TROMMELS and *kulibinas* washing machines at the Lena gravel mine, Siberia, have been replaced by long sluices of the Alaska type, resulting in less losses of gold and lower costs, namely, 56 to 35 cents per cubic yard.

COST of producing steam power at the Copper Queen reduction works, where oil is used direct under boilers, and other boilers are in the reverberatory-furnace flues, is $60.436 per hp.-year. An average of 4507 hp. is developed.

CONCENTRATE from the Brunswick gold mine, Grass Valley, California, is shipped to smelters for treatment. In 1915, 376 tons, worth $70.311 per ton, cost $17.125 per ton. The amount of mineral in the ore averaged 1.71 per cent.

STEAM-SHOVELS find their principal use in mining at open-cut iron mines, such as in Minnesota, and at the extensive 'porphyry' copper mines. At the Wasp No. 2 mine in South Dakota a steam-shovel handles gold ore up to 500 tons per day.

WORKMEN deprived of a forearm through accidents can be fitted with a magnetic hand. As devised in Germany, this hand permits a workman to operate a file, plane, lathe, etc. The hand contains an electro-magnet, and connection with electric current is made by the foot or the other arm.

DYNAMITE and linoleum consume over 20,000 tons of wood-flour, costing $300,000, per year. A white flour is demanded for the dynamite, as the freshness of the explosive is indicated by a light color. The flour must be very absorbent, so that the nitro-glycerine will not leak out. Wheat flour is also used in dynamite.

'SUBMERGENCE' in air-lifts, as used for raising water from mines or oil from wells, is the depth that the air-pipe is submerged below the pumping level of the water or oil. The 'percentage of submergence' is the proportion of the total length of pipe submerged in the water when pumping. Low lifts require proportionately more submergence than high lifts; for a lift of 20 ft., 66% submergence is necessary; for a lift of 500 ft., 41%. In some cases of deep pumping the submergence is only 30 per cent.

A STEEL HEAD-FRAME is generally considered to cost 50% more than a timber structure of the same kind, but is, of course, much more satisfactory. An 85-ft. two-post steel head-frame recently erected at the Brunswick vertical shaft at Grass Valley, California, cost a total of $5873. Of this cost, $4086 was for materials and $1787 was for labor. Of the materials, the structural fabricated steel cost $3587 and the sheaves $384. Of the labor cost, the erecting-contractors were paid $676; $412 was paid for concrete foundations; and $291 for work of an engineer and draftsman.

AN ELECTRO-HYDRAULIC shovel, as used by the Penn Iron Mining Co. at Vulcan, Michigan, employs water under pressure to perform all the operations except propelling, for which a separate motor is best suited. A motor-driven centrifugal pump mounted on the shovel discharges into a pressure tank; there are water-cylinders and plungers with a suction-tank into which the cylinders discharge and from which the pump draws its supply. One man operates the shovel, the average speed being three or four dippers per minute; by utilizing the water as a medium, peak loads are avoided in the electric power requirements.

PLATINUM is found in some copper ore near Ketchikan, Alaska, and the miners consider that they should receive payment for the platinum content of the shipments sent to the smelters. As far as can be found no smelter in the Pacific Coast States pays for platinum in such ore. During 1914 refiners of platinum sand, gold bullion, and copper matte reported that 3430 oz. of new refined platinum was recovered by them. Of this quantity 525 oz. came from domestic crude placer platinum, and at least 2500 oz. was derived from domestic sources, the remainder from foreign material treated in the United States. The price of platinum has risen considerably of late, and as will be found quoted on the metal page of this journal each week, is from $88 to $92 per ounce.

OIL AND GASOLINE are used at mines for many purposes, and frequently cause fires which are difficult to put out. A soda-foam is now on the market that will extinguish fires in receptacles containing from a gallon to a 55,000-bbl. tank. Foam has many distinct advantages. It can be thrown to a distance of more than 30 ft., and can be used on highly inflammable liquids without spattering them or without spreading the fire in the least degree. It floats on the lightest oils, and, being discharged in a state of continuous expansion, it spreads itself completely over an oil surface in the form of a blanket, entirely shutting off atmospheric oxygen from the burning surface. In its application as a stream, or jet, none of the carbon dioxide is lost in transit. This gas is carried in minute gas-bubbles direct to the seat of combustion in the form of a foam blanket, which remains for almost an hour. The foam has a cooling effect on all fires, but this is especially noticeable in oil fires, the oil being cooled below its flash-point, thereby preventing re-ignition. The foam is adhesive, sticking to ceilings and walls, or anything upon which it is thrown, and there remains until long after the fire is extinguished. The foam damages nothing and can be readily removed by washing. For small fires the mixture is sold in apparatus similar to the ordinary fire extinguishers.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

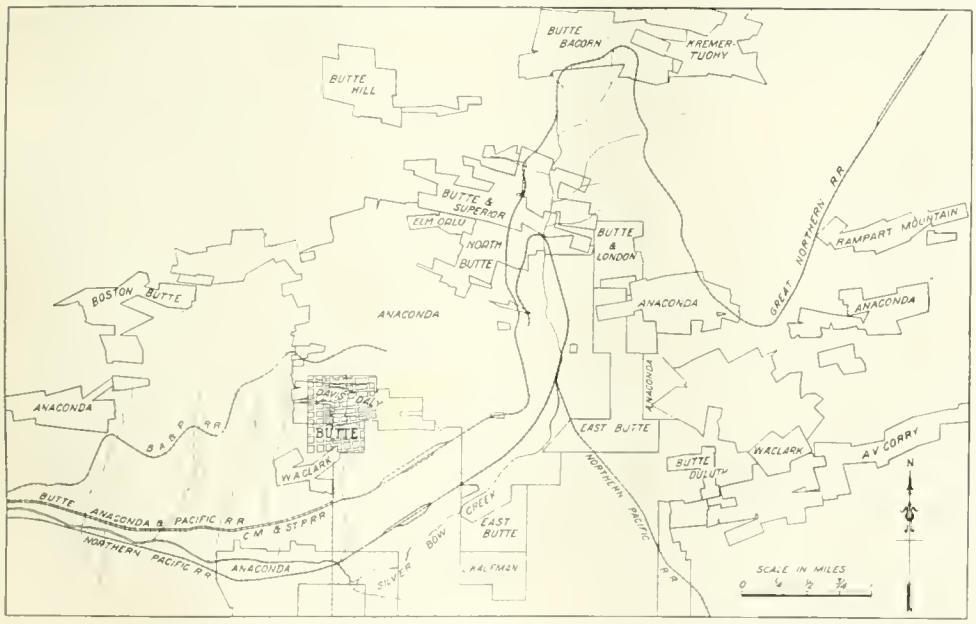
BUTTE, MONTANA

Butte & Superior, Anaconda, Butte-Ballaklava, East Butte, Bullwhacker, and Labor Trouble at Pilot Butte.

The Butte & Superior company treated 54,380 tons of ore during February (29 days), a daily average of 1875 tons, in a mill that was originally designed for 1000 tons. An idea of the improvements in treatment can be gained by a comparison with the corresponding month of 1913:

Month of February	Ore treated, tons	Extraction, per cent	Concentrates, tons	Zinc concentrates, pounds
1916	54,380	91.94	14,866	15,645,000
1913	16,100	76.85	5,154	4,886,710

Five new sets of ball-mills and tube-mills are being installed.



PRINCIPAL PROPERTIES AT BUTTE, MONTANA.

Some new filter-presses and a new compressor with a capacity of 5000 cu. ft. of air per minute will also be erected. The reported cutting of a large new orebody on the 1600-ft. level is the same that is being worked on the upper level. It is wider at 1600 ft. than on the levels above, and averages from 18 to 20% zinc. The new shafts are down 300 ft. Raising on the shaft has been started from the 1200 and 1300-ft. levels, and it is expected that the shaft-raises will be up to within 750 ft. of the surface by the time the shafts reach that depth.

The Robert Emmet lodes No. 1 and 2 were purchased at public auction from the Butte Copper Co. by the Anaconda company. The consideration was $55,000, but the buyer already owned a ⅓ interest in No. 1, and a ⅔ interest in No. 2, so that the amount that will be paid the Butte Copper Co. for the balance of the two will be about $30,000. It has not been decided whether this money will be used to further develop other properties of the Butte Copper Co., or whether it will be distributed to the shareholders.

In accordance with the terms of its option on the Douglass property the Anaconda company has started development. The Douglass is one of the promising zinc-lead prospects of the Pine Creek district of the Coeur d'Alene, Idaho. There are about 1200 ft. of adits in the property, and these will be extended. The ore so far opened averages 17% zinc and 6% lead. If sufficient ore can be blocked-out it will be treated by the new wet process developed at Anaconda. (This process does not recover the lead). The option is in the form of a lease and bond, and runs for a period of three years from December 16, 1915. The total consideration is $256,050. The outstanding shares of the Douglass company total 853,000; the rest of the 1,200,000 shares authorized are in the treasury of the company. The purchase price represents 30c. a share on the outstanding stock. Royalty to be paid on all ore shipped is $3 per ton and will apply on the purchase price.

The experimental zinc plant at Anaconda is yielding 9 tons of zinc a day. It is being enlarged, and will soon have a capacity of 25 tons. Construction work is being rushed on the zinc plant at Great Falls. This plant will have a capacity of 70,000,000 lb. of zinc per annum, and will cost about $2,000,000. It was planned to have the work completed in July. The company is receiving all the copper ore its works can treat.

It is understood that arrangements have been made with the Anaconda company whereby it will mine for the Butte-Ballaklava the ore that is now being developed in a drift from the High Ore mine that corresponds to the 2200-ft. level of the Ballaklava. This is 600 ft. below the bottom of the Ballaklava shaft. The Ballaklava is now mining 250 tons of ore per day. Most of the ore comes from 800, 1000, 1200, and 1600 ft. Considerable development is being done on the 1600-ft. level.

The fire in the Pennsylvania mine in which 21 men lost their lives is gradually being brought under control, and concrete bulkheads are being put in to confine it. The air-shaft which caved soon after the fire started is being re-timbered, and new pipe-lines for compressed air are being put down. The upper levels are producing some ore, and about 300 men are at work clearing up the lower levels, where the fire has been driven back, and putting them in shape to operate again. The normal capacity of the Pennsylvania is about 800 tons per day, and the output will be increased as conditions warrant it until the former daily average is being handled.

A shift-boss shot and killed a station-tender working under him at the Pilot Butte mine. The trouble started when the shift-boss sacked a socialist for not doing his work properly. The latter was one of the leaders in the Miners' Union trouble in June, 1914. All the men known to be instrumental in creating disorder at that time were blacklisted by the Anaconda company. The North Butte and Butte & Superior companies use the Anaconda company's 'rustling-card' system, so

those men with anarchistic tendencies were forced to seek employment at the smaller independent mines. Many of them found work at the Pilot Butte. The station-tender and the man that was discharged were socialists of the same order. The shift-boss was underground between shifts early one morning, and the station-tender argued with him for discharging the socialist. The station-tender jumped on the cage when the boss was ready to go up, and they went to the surface together. At the shaft-collar the station-tender started an attack, but the shift-boss broke loose and ran for the office. He secured a gun and fired at the other as he was coming through the door. The shot proved fatal. The shift-boss was released on $10,000 bonds, which were furnished by the president of the Pilot Butte company.

At the close of business last month the East Butte company had about $475,000 cash and copper on hand. The output for February was 1,277,160 lb. compared with 1,060,000 lb. in January. The average copper content of the ore being mined now is considerably less than that extracted in 1915. However, with the 20% increase in production, the company should show a profit of $100,000 per month, at the present price of copper. The ore developed at 1500 ft. is of higher grade than that at 1200 feet.

About 150 tons of ore per day is being shipped from the Bullwhacker to the Tacoma smelter. The ore contains about 3% copper, which occurs as chrysocolla. Ore extends close to the surface, and the glory-hole system of mining is employed. The west wall caved-in recently, and several hundred tons of ore fell to the bottom. The accident occurred between shifts and no one was injured.

JOPLIN, MISSOURI

NORTH WEBB CITY MILL TO BE MADE ONE OF THE LARGEST IN THE DISTRICT.—SLUDGE DEPARTMENT OF LARGE CAPACITY AT A. W. C. NO. 4.—DRAINING AURORA LAND, AND LARGE DIKE TO PROTECT MINES.

The Hurry Up Mining Co.'s old 300-ton concentrating plant, in the north Webb City district, is to be dismantled and replaced with a practically new one of 400 tons' capacity per 10 hours. The mill is one of the pioneers of the North Webb City field, having operated almost continuously since it was erected 10 years ago. During periods of both high and low ore prices the plant has been a steady producer and in recent months, since prices have been so high, has been working double shift. The reconstructed plant will be equipped with rougher-jigs, one cleaner-jig, crushers and rolls, tailing-elevators; everything being new except the framework of the plant. In addition to the new machinery at the mill the company will begin hoisting ore from what is known as the Florence shaft, 1000 ft. north-east of the mill. Work of construction on the mill and tramway and on a new 1200-ton hopper at the mill will be started the middle of April. Electric power will be used. The company is operating in a sheet-ground district where the recovery of blende and galena average between 2 and 3 per cent.

One of the largest sludge-mills of the district is being constructed by the A. W. C. Mining Co., in conjunction with the work of building its new No. 4 plant, on a 160-acre lease of the Luke land, in the west Joplin district. The sludge department is 200 ft. east of the mill, and slime will be fed by launders from the main plant. Sludge first passes into a 40 by 40-ft. concrete settling-tank, after which it goes to a 36-ft. Dorr thickener. There will be 11 tables in the sludge department. The No. 4 mill is the fourth of a series of plants to be built by this company. Work of construction on this mill was under way before the transfer of the property, several weeks ago, for $200,000, to Gibson and associates. The mill will have a capacity of 400 tons a shift, and will be operated full time. Electric power will be used throughout. A double-compartment shaft, 7 by 12 ft., will supply ore, which comes from sheet ore formation at a depth of 190 ft. The plant has two rougher-jigs, one cleaner, one 18-in. breaker, one set of 42-in. rolls; and two sets of 36-in. rolls. The mill is in a district that has commanded considerable attention recently. A short distance to the north is the Samson mine, recently purchased by W. Kenefick for $125,000. Immediately to the north-east is the Gibson mine, and to the east are the S. Y. Ramage and the Once More mines, all of which are equipped with large concentrating plants. A few years ago no development was under way in this particular part of the field, the ore generally being too thin to operate at existing low prices.

A 40-acre tract of the United Zinc Co.'s land at Aurora, that has been under water for more than a month, is now being drained with a 10-in. Texas pump installed by W. H. Hunter, of Aurora. More than a dozen small operating companies are awaiting the drainage of the land before resuming work. Although each mine is of comparatively small importance in itself the combined output from all the properties has made the tract a big producer. Heavy rains recently caused every mine on the land to be flooded. The work is conducted at varying levels, no mining having been undertaken below a depth of 100 ft. Much of the ore consists of calamine and lead, occurring at shallow levels, some of the mining being done within 25 ft. of the surface.

Lead and calamine in soft ground are indicated in recent drilling on the Rose land, south of Joplin, and following these drill-strikes a new shaft is being sunk. It is now down 109 ft., and is expected to open 'pay-dirt' at a depth of 125 ft., extending down to 135 ft. In this company are James Clark, Jake Warren, J. B. Avery, and A. S. Baldry. The development of shallow mines in the south Joplin field is becoming extensive, and many good discoveries have been reported recently.

Plans for the building of a 1200-ft. dike on the United Zinc Co.'s land at Peacock, 5 miles north-west of Joplin, have been altered somewhat and much more money is now to be spent in this work than at first proposed. Instead of constructing an earth and rock dike, the new work will consist of concrete, the wall being 3 ft. wide at the base, 1 ft. wide at the top, 12 ft. high, and 1200 ft. long, protecting the mining ground from flood waters of Spring river and Center creek. A. B. Bensch, of New York, has acquired a lease on 493 acres of the United Zinc Co.'s land at this point, and has installed two large Texas pumps, and will put in another in the near future. All the pumps are to be operated by electricity. Several weeks will be spent in draining the old Peacock mines, which were highly productive from 1899 to 1909, but which have not been in operation for a number of years. Mr. Bensch plans to begin the construction of a large concentrating plant in the near future.

PETROGRAD, RUSSIA

CONDITION OF RUSSIAN GOLD DREDGING IN 1914.

The report on gold and platinum dredging in Russia during 1914 has been issued by the Consultative Committee of the Gold and Platinum Producers. It is somewhat briefer than usual, excepting the tabular matter, which gives many details. It is stated that the question-forms issued by the Committee were filled and returned by 13 gold-producing concerns controlling 58 dredges, three more boats than in 1913. There was an improvement in particulars given on 53 boats, five more than in the report of 1913. Four companies failed to make any returns at all, namely, the Moscow Timber Co., the Orsk Gold Co., the Northern Yenissei Gold Co., and the Spassky. As was to be expected, the time worked was short of that in the preceding year, though certainly not so far below as a state of war might have justified. The hours worked were 2951 per dredge compared with 3302 in 1913, and 3437 in 1912. The quantity of gravel washed shows a reduction that is a fair proportion compared with peace times. What is perhaps more surprising is that the returns in gold and platinum, though of course lower than those in 1913, are

relatively higher per dredge and in total. The quantity of gravel washed per dredge was 18,451 cubic sajenes (1 sajene = 7 feet) in 1914, against 19,502 in 1913 and 16,806 in 1912. The resulting production of gold per dredge was R92,860 (1 ruble = about 50 cents) in 1914, against R92,360 in 1913, and R84,200 in 1912. The reduction in working hours per dredge made 10.6%, but the average gravel washed and the average precious metal produced made respectively a reduction of 5.39%, and an increase of 0.5%. The total quantity of gold and platinum produced by the dredges in Russia and Siberia in 1914 showed a decline of R149,730 compared with 1913, making a reduction of about 2.5%. The grand total of gold and platinum produced from 58 dredges according to the table made R5,205,290. But dealing only with the 53 dredges, respecting which complete details are available, the quantity was R4,921,580; or an average of R92,860 as is stated above. The results per dredge for previous years have been given for purposes of comparison, but one need only say that in 1910, when the result was R73,000, and again in 1906, when the result per boat was no more than R54,100. This, as can be understood, does not necessarily indicate increased efficiency to the extent of the difference between the fignres of 1906 or 1910 and 1913, because the dredges now at work are considerably larger.

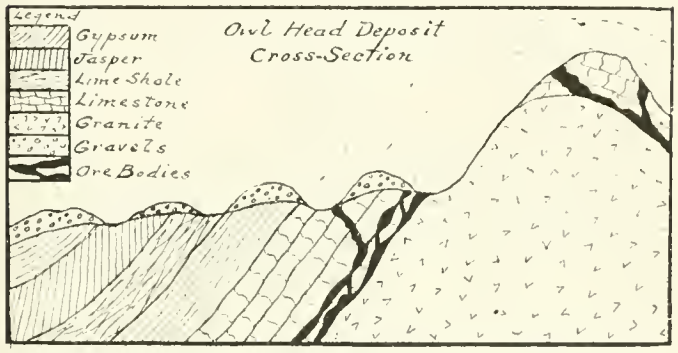
The vexed question of duty or no duty on imported dredges or parts thereof, and sinking apparatus, is always being discussed by mining men on the one hand, and the advocates of Government revenue on the other; but an important decision has been taken by the Committee not long ago appointed to examine the conditions of the Russian gold industry, with the object of suggesting measures for its extension and improvement. It is now announced that the Committee has taken at least one important step, and has resolved that it is now time and would be of great advantage for the development of the industry, and for the increase of the gold reserves of the Russian empire, to establish for 10 years from the day that peace was arranged, the duty-free importation of dredges or parts thereof, or apparatus for investigating gold-bearing areas. At present immense areas of low-grade sands are allowed to lie unexploited, which might give Russia the gold which is so necessary at all times, especially at present. The Gold Industries Committee on its part is taking advantage of the new situation, and is giving evidences of energy and enterprise in the sense that it would place the dredging business in Russia on such a level as would insure the production not of R4,232,000 or R6,348,000 of gold, but many times this value. The concession to the gold industry indicated would make Russia a great market for dredges as well as parts thereof, and at the same time would stimulate the domestic factories to develop the cheap, rapid, and extensive and modern construction of gold-dredging machinery and accessories. It may be mentioned that the guiding hand in the Committee is D. E. Konovaloff, who thoroughly understands the business.

It may be mentioned that, in consequence of the loosening of organization, which naturally accompanies war conditions in distant industrial centres, the clandestine removal of gold has become a grave question. In past years it was well-known that considerable quantities of metal was being removed from the country by improper means, and it is found that in 1911 this had increased considerably, also in 1915. How this affects the question of the registration of gold and platinum will no doubt be made clear later on, but it is obvious that registration is not a complete remedy for what must always be a strong temptation in the goldfields.

SILVER LAKE, CALIFORNIA

NOTES ON MANGANESE DEPOSITS.

About 30 miles west of the Tonopah & Tidewater railway, with which it is connected by a fair wagon-road, is the Owl Head manganese mine. The nearest post-office is at Silver Lake, in San Bernardino county, 45 miles distant. A 30-hp. caterpillar tractor of 20-ton capacity hauls ore to the line, making a round trip in 30 hours. The present output is 200 tons monthly. The property is at an elevation of 2000 ft. above sea-level. The deposit was discovered by R. L. Mann, the owner, in 1911. The accompanying section illustrates the



SKETCH SHOWING OCCURRENCE OF MANGANESE.

geologic conditions. In what may be called 4 "ore occurrences" are 10 deposits of manganese of various lengths and thicknesses. The product sent to market contains 76.80% manganese dioxide, 6.56% manganese oxide, 3.93% barium oxide, 0.022% phosphorus, 3.58% silica, 1.12% ferric oxide, 1.03% alumina, 2.85% lime, 1.45% magnesia, and 2.6% moisture, etc. There is also in reserve a large quantity assaying 45% metal, with less than 3% iron, 5% silica, and 0.02% phosphorus.

CRIPPLE CREEK, COLORADO

GOLD YIELD IN MARCH.—TUNGSTEN EXCITEMENT.

Gold output from the mines of the Cripple Creek district in March, as reported by the mills and smelters, is as follows:

	Tons	Average value	Total value
Golden Cycle, Colorado City	35,000	$18.00	$630,000
Portland, Colorado Springs	11,500	23.10	264,500
Portland-Victor mill, Cripple Creek	17,500	3.17	55,475
Portland-Independence, Cripple Creek	14,900	2.03	30,247
Isabella, Cripple Creek	2,160	2.40	5,184
Caley-Jerry Johnson, Cripple Creek	1,312	4.50	5,904
Smelter, Denver and Pueblo	4,300	55.00	236,500
Total	86,672	$14.17	$1,227,810

On April 10 the Golden Cycle paid its monthly dividend of 2c. per share, equal to $30,000.

The March production from the Beacon Hill estate of the El Paso Consolidated is reported as being 2900 tons. This is the largest quantity recorded for any month in over three years. With the starting on April 1 of the split-check system for lessees, optional with them, the output is expected to be considerably increased.

Much interest has been aroused in the district by the report of a rich tungsten discovery between Dale and Wilbur, about 10 miles south-east of Victor. A trial shipment of between 250 and 275 lb. of wolframite, said to contain from 60 to 72% of tungstic trioxide, has been tested here and sent on to Denver for further analysis. The Wolframite Gold Mining Co., a Colorado corporation with offices at Wheeling, W. Va., controls the claims where this ore was found. Gold, silver, and copper are also in the ore. Some of the old time excitement prevails among prospectors; many have set out on foot with pack-horses or burros to locate claims and obtain leases from the ranchers who own the land near the find. Quite a few claims have already been located, but weather conditions lately have somewhat delayed the fortune-seekers.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ARIZONA

In Bulletin No. 17 of the State Bureau of Mines, A. C. Rubel discusses coal in Arizona. This mineral is found in the Deer Creek field of eastern Pinal county, and the Black Mesa field of Coconino, Navajo, and Apache counties. The coals are not of high grade, and generally considered the deposits are not likely to be worked in the immediate future.

Greenlee County

On March 29 the employees and the Arizona, Detroit, and Shattuck companies signed an agreement covering general rules for working conditions, grievances, and wages in the Clifton-Morenci-Metcalf district. It is to be printed in English and Spanish, and is about 4000 words in length.

At 100 ft. and 800 ft. in the Shattuck-Arizona 7% and 6% copper ore has been opened. The daily output is 450 tons of lead and 550 tons of copper ore.

Mohave County

As depth is reached in the Oatman district water is encountered, and at 500 ft. up to 1000 gal. per hour is the flow. Pumps are to supersede bailers. The water is of good quality for domestic and mine use. Water supply has been a problem, and this will help, aided by the piped supply from the Colorado river, 12 miles distant.

Yuma County

According to the *Parker Post* there is unusual mining activity prevailing in the northern part of this county.——The Empire-Arizona is shipping by auto-truck to Parker.——Development is reported as good in the Billy Mack and Zerolite-Mammon mines.——The Swansea made a profit of $22,000 in February from 4% copper ore. A large orebody has been opened.—The Planet is shipping 40 tons of 18% ore daily per motor-truck to the railway.——Manganese claims on the Planet range are to produce 200 tons a day. They are 8 miles from the railroad.

CALIFORNIA

Amador County

(Special Correspondence.)—The Amador Star Mining Co., 3 miles north of Plymouth, is sinking a vertical 3-compartment shaft to 500 ft., and will then cross-cut to the vein at that depth. The property is equipped with a steel head-frame, 200-hp. electric hoist, and air-compressor. This was formerly known as the Rhetta mine. Bayliss C. Clark is superintendent.

The old Orr or Creek Ledge mine prospecting shafts are being unwatered for sampling and exploration. This work is being done by the Plymouth Consolidated company or kindred interests.

Plymouth, March 20.

The Plymouth company has raised wages 25c. per shift, effective April 1.

Butte County

As the electric properties of the Oro Water, Light & Power Co. have been absorbed by the Pacific Gas & Electric Co., its dredging department is to be transferred to a new company, the American Gold Dredging Co. The Victor dredge of the company near Oroville sank on April 5. It had nearly completed digging a small area, and was then to be dismantled.

Calaveras County

(Special Correspondence.)—The Vanciel brothers are opening the Star and Excelsior mines at Eugene. These properties produced a good deal of gold and copper years ago. The McNulty mine, owned by the Malspina brothers, joins this property on the south. All have production records, back in the sixties, when ore was shipped to Swansea, Wales. With the present high price of copper, and enough working capital it is expected these mines will soon be among the regular producers.

Eugene, March 25.

(Special Correspondence.)—Coughanour and Olesen and others are operating the Napoleon mine. An oil-flotation plant, with a capacity of 50 tons per day, is treating the ore, which is crushed in a Hendy ball-mill through a 60-mesh screen, 80% passing 80-mesh. The owners are working on ore left by early operators, when the best was hand sorted and shipped to Swansea, Wales, for treatment.

Copperopolis, March 25.

(Special Correspondence.)—At the Mountain King mine, sinking is proceeding from the 500 to the 700-ft. level. The vein, followed by the working shaft, lies at an incline of 30° to the east, and at the bottom of the shaft, shows a width of 7 ft. of good ore. Work is done with electric power. A 10-stamp mill will be kept crushing ore from the bottom of the shaft. C. M. Brown is superintendent.

Hodson, March 27.

(Special Correspondence.)—The Gray Lead mine has been sold by T. Porteous to S. F. Johnson and others of New York. This mine was once a good producer, and has been opened at depth by a cross-cut adit, exposing a good vein. Assays returned $166 over a width of 18 in. A recent mill-run by lessees on another vein of this property averaged $70 per ton.

The Zacaterre mine, in which sinking has been in progress, is opening satisfactorily. A quartz vein, 12 to 24-in. wide, assaying $40 per ton, has been exposed in the shaft. T. Porteous' stamp-mill has been leased by the Zacaterre people.

At the Deerfoot mine sinking has been done, good-grade ore being opened.

West Point, April 5.

Inyo County

As soon as the Wilshire Bishop Creek mine can be financed work will be resumed and the mill enlarged to 150-ton capacity. The Consolidated Wilshire Mining Co. has been formed to do this.

Fourteen tungsten claims 8 miles west of Bishop have been sold to A. J. Clark of Los Angeles. Fully $40,000 must be spent before production commences. A mill will be erected.

During the five months ended February 29 the Cerro Gordo Mines Co.'s profit was $40,260. Shipments of 1000 tons of zinc ore monthly are being made.

Nevada County

For $25,000 the Columbia Consolidated Mines Co., managed by E. C. Klinker, has purchased the claims of the late Fritz Meister, on Canyon creek, three miles above Washington. A working arrangement has been made also with the Ocean Star owners, whose property adjoins the Columbia. The two 10-stamp mills will be started.

The Texas, Guild, and Niagara quartz mines in the Willow Valley district have been bonded to W. H. Tuttle of Reno. The first has a 515-ft. shaft and 10-stamp mill.——The Montana, Willow Valley, Buckeye, Cold Springs, Benton G., and

Lone Star claims, of 1000 acres, were recently consolidated here.

The North Star Mines Co. has declared its regular quarterly dividend of $50,000.

Owners of the Union Hill mine were recently paid another installment of $25,000 on the purchase price of $79,000 by the present operators.

During the year ended March 1, 1916, the Golden Center of Grass Valley Mining Co. did 2200 ft. of development; crushed 7969 tons of ore; recovered gold worth $112,352 and concentrate valued at $21,638, a total of $133,991, an average of $16.81 per ton; paid $58,000 for property, etc.; erected plant costing $35,401; made a profit of $49,843; and paid $21,990 in dividends. Good developments are expected during the current year. C. A. Brockington is superintendent. Additions are to be made to the mill, and a cyanide plant has been designed.

Placer County

The Live Oak, Big John, Red Bird, Black Oak, and Annie Laurie mines, near Colfax, are being re-worked.

San Bernardino County

Near Danby the Gold Reef Mining Co. has acquired title to extensive holdings in a promising district. It has adopted the leasing system of development. Leases are limited to 500 ft. along the lode, but lessees are not restricted to one lease. Work must be done continuously. The conditions of leases are 10 years at 10%, with privilege of renewal. All original development costs are to be returned to lessees from output before royalties accrue. Therefore money goes into the ground and must come out again before the holding company participates. The lodes are said to be of the Oatman character. A report has been made by Ellis Mallery.

Shasta County

During March the Mammoth Copper Co. shipped 2500 tons of 40% zinc ore to Kansas smelters.

Trinity County

Two thousand acres of gravel claims near Hayfork have been bonded to E. T. Wiltsee for $50 per acre. Drilling has commenced in charge of J. A. Scott of San Francisco. 'Pay' is 12 to 18 ft. deep, and averages 6c. per yard. A large dredge is contemplated.

Tuolumne County

(Special Correspondence.)—A company operating in this county is negotiating to acquire the Dreisam mine, at Arastraville. It is expected that the deal will be consummated within a few days, and that the mine will be re-opened without delay.

The Pine Log Gold Mining Co., composed of residents of Stockton, will shortly begin mining operations on the south fork of the Stanislaus river, just below the mouth of Five-Mile creek. The property, acquired under lease from a San Francisco company, is a bar that was partly worked in the early days with good results. A wagon-road is being constructed to facilitate the transportation of machinery and supplies. A steam plant and pump will be installed as soon as possible, and if the water cannot be handled in this manner a dam will be constructed across the river and the stream conveyed to a point below the property in a flume. Henry W. Schroeder will direct operations.

A Cameron pump with a capacity of 400 gal. per min. is being installed on the 500-ft. level of the Rawhide mine.

Considerable new machinery has been erected at the Dutch-Sweeney mines since the properties were taken by the present operating company. A residence for W. J. Loring, the general manager, has also been built. The extraction of ore and the development of new orebodies is giving employment to a large number of men, and results are said to be highly satisfactory. The group includes the Dutch, Sweeney, and App mines.

The Shore and Oliver mines, situated on Table mountain, near Jamestown, have been bonded to A. M. Hennessy, of San Francisco. Work must be commenced within 60 days, by the expiration of which time a substantial payment is to be made.

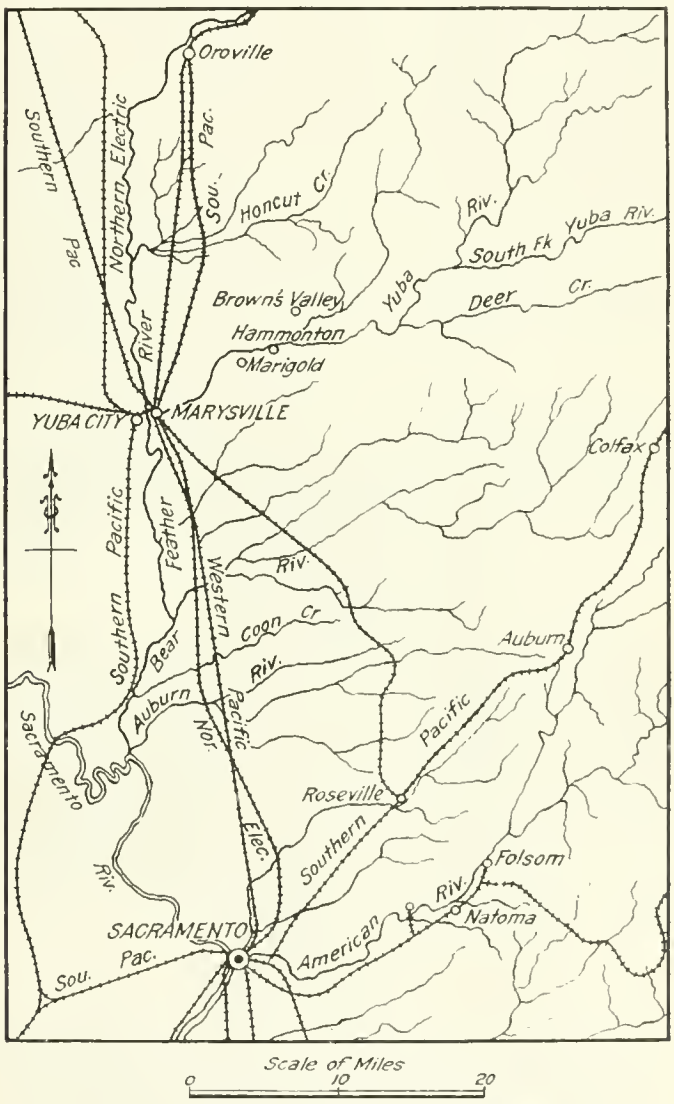
Fred Stucki is developing a vein 18 to 48 in. wide near the Mohican mine, which yields $10 gold per ton.

Fifty tons of high-grade ore from the Live Oak mine is being treated at the Black Oak. The operators, Stage and Blackburn, expect to be milling from 50 to 100 tons per month in the near future.

Sonora, March 27.

Yuba County

A dredge for the Guggenheim interests will soon be constructed between Hammonton and Park's Bar bridge, opposite Brown's Valley, as a spur track is being laid to the Yuba



MAP SHOWING OROVILLE, YUBA RIVER, AND NATOMA DREDGING DISTRICTS OF CALIFORNIA.

river by the Southern Pacific company. The boat is on its way from the East. Other dredging companies on the Yuba are the Marysville at Marigold and Yuba Consolidated at Hammonton.

One hundred tons of chrome-iron ore daily is being extracted from the Woodleaf Canyon mine in the northern part of this county. A. Brendt is in charge of 50 men.

COLORADO

Boulder County

The Omaha tungsten claims of C. C. Ficcio on Boulder creek have been sold to Kansas City people for $60,000.

A mill to cost $50,000 is to be erected in Boulder canyon by the Tungsten Metals Corporation of Boulder, which has acquired several properties.

The Boulder Tungsten Production Co. is to rebuild the Coburn mill at Eagle Rock, making it of 50-ton capacity. John G. Clark is in charge.

DOLORES COUNTY

After having its property worked by lessees for a long time, the Rico Mining Co. has resumed operations on its own account at Rico.

LAKE COUNTY (LEADVILLE)

On April 2 fire at Leadville destroyed city property valued at $50,000.

The Robert Emmet, Forest City, Result, Gonabrod, and Ranchero claims of the Small Hopes-Boreel Mining Co. in Stray Horse gulch have been sold for $500,000 to the Empire Zinc Co. The property has been worked through the Robert Emmet shaft. High-grade zinc-lead-silver ore occurs at 600 ft., and recent production has been over 1000 tons per month. Several shafts in this area are down 1000 ft., and some are 1350 ft deep. The new owner is to unwater the shafts. The Small Hopes company is composed of well-known business and mining men, with Frank Zaitz as president.

As at the Penrose shaft of the Down Town company a pump-motor at the Harvard shaft of the U. S. S. R. & E. Co. burned out last week, delaying unwatering somewhat. Peculiar conditions are responsible for this trouble.

OURAY COUNTY

During February the Camp Bird made a profit of $36,000 from 2330 tons of ore.

Thirty inches of good copper ore has been opened in the 1000-ft adit of the Calliope claims, four miles south-east of Ouray. The Harper-Larson Development Co. is doing the work.

Some high-grade tungsten ore is being mined near Ironton.

MISSOURI

JASPER COUNTY

During the last week of March there was little change in the ore market at Joplin; prices ranged from $85 to $115 per ton for 60% zinc product. The Missouri-Kansas-Oklahoma region produced 1683 tons blende, 409 tons calamine, and 1375 tons lead, averaging $100, $84, and $99 per ton respectively. The total value was $850,768. The principal producing areas were Webb City-Carterville, 2661 tons blende and 643 tons lead; Joplin, 1002 tons blende and 110 tons lead; Duenweg, 685 tons blende; Galena, 576 tons blende and 83 tons lead; Miami, 385 tons blende and 385 tons lead; and Oronogo, 347 tons blende and 74 tons lead.

MONTANA

GALLATIN COUNTY

Through the efforts of Thomas Michner of Salesville, the holdings of the principal placer mining companies in the Gallatin valley, near the Yellowstone National Park, comprising approximately 6000 acres, have been taken over by the Gallatin Gold Dredging Co., a corporation recently organized at Spokane, capitalized for 2,000,000 shares at $1 each. Directors of the new concern are Dr. William B. Pickrell, Dr. Frederick Epplen, and George Harding, Spokane; H. D. Chapman, Chicago; H. M. Rheiling, Denver; and Mr. Michner. It has taken Mr. Michner six years to consummate this deal. The ground, comprising one of the richest placer fields in Montana, has never been worked, except at the lower end, where considerable coarse gold was found, leading those who have examined the deposit to think that good gravel will be encountered all the way up the stream. The pay-gravel is from 300 ft. to half a mile wide, and extends 22 miles down the west fork of the Gallatin river from a point near the north-east corner of the Yellowstone Park. Half of the stock of the Gallatin Gold Dredging Co. has been taken over by Dr. Pickrell, Mr. Chapman, Mr. Harding, and Mr. Rheiling, who will supply the money to thoroughly prospect the holdings and later to install dredges to work the deposit. The corporation takes over the properties of the Eureka Development and Hercules Dredging companies, comprising 1200 acres of patented and 4800 acres of unpatented land, much of which is exceptionally well suited to dairying and stock raising. The agricultural area will be leased from the company by Mr. Michner and associates, who will embark in the livestock business as a side issue, as there is a large territory adjacent that can be used for open range.

SILVERBOW COUNTY

The Butte-Detroit Copper Co. is being organized with a capital of 2,500,000 $1 shares, which are offered to the public at 70c., to operate the Ophir mine at Butte. The shaft is to be sunk from 1000 to 2000 ft. W. L. Creden of Butte is managing director, with Sir Henry Pellatt and Sir Frederick Borden on the board of directors.

The Pilot-Butte property of 5 acres has been finally sold to the Anaconda company for $1,100,000. This gives the late shareholders $12.50 per share. The mine is opened to 2600 ft. Considerable zinc ore occurs.

The Butte-Alex Scott company is being liquidated, and shareholders will receive $10.50 per share for the first distribution. The property was purchased by the Anaconda.

Liabilities of the Butte & Duluth Mining Co. are $42,369 for wages, $118,628 for accounts payable, and $500,000 outstanding bonds.

The Butte & Bacorn company is to be reorganized, by forming the Great Butte Copper Co. with a capital of $1,000,000 in $1 shares, with exchange of shares and sale of 400,000 at 66c. each. The Calumet shaft of the Butte & Anaconda will be purchased for $19,000, and exploration commenced at a depth of 1500 feet.

The du Pont Powder Co. has purchased 1200 acres of land near Butte on which to erect a dynamite plant costing $500,000. This will supply explosives for mines in Idaho, Montana, and Utah. Increased mining activity decided the company to construct this plant. Nitrate will come from Chile, while acid will be secured at Butte from the smelters.

NEVADA

ESMERALDA COUNTY

Gold-copper ore of fair grade has been opened in a number of workings of the Florence Goldfield.

In raises put up above the 1175-ft. level of the Sunflower claim of the Merger company, the shale-latite contact has been opened 5 to 20 ft. above the cross-cuts, but shows no commercial ore.

The Jumbo Extension continues to ship 100 tons daily, some good ore coming from the 800-ft. level. Exploration at 890 ft. at the Velvet shaft is in virgin ground, and results are watched with interest. The main east cross-cut at 1017 ft. is being driven to the Velvet.

Drilling is in progress at 700 ft. in the Silver Pick.

The 50-ton flotation plant of the Nevada Metal Extraction Co., on foundations of the old Florence Goldfield mill, is ready for work. A. F. Mead is in charge.

At the Pioneer, 60 miles south of Goldfield, the mill is treating up to 40 tons per day. A rich shoot was recently opened at 170 feet.

The estimated production of the Goldfield Consolidated company for March is as follows:

Ore mined, tons	30,000
Gross extraction	$210,000
Operating expenses	156,000
Net realization	$ 54,000

The 50-ton flotation plant is recovering 92% of the gold and 99% of the copper. This is so satisfactory that a 500-ton unit,

of 24 Callow cells and accessories, has been ordered. This will cost $18,000. The flow-sheet is extremely simple. Concentrate is to be treated as at present. Coal-tar, creosote, and pine-oil are used, costing 8c. per ton treated.

The Booth company is paying 10c. a share, or $100,000, on April 26. This is from cash on hand, not from mining operations.

Elko County

Mines at Jarbidge now show more ore developed than before, and additions to mills are contemplated. Operators are arranging with county officials to co-operate in constructing a good road from Elko to Jarbidge, to be serviceable in all seasons.

NEW MEXICO

Dona Ana County

The Bennett-Stephenson, Memphis, Torpedo, and all the principal properties from the Modoc to the Excelsior in the Oregon Monntain district, have been bonded to Phelps, Dodge & Co., for $1,500,000. These mines have produced a good deal of lead, silver, copper and zinc ores. Development has been spasmodic in recent years.

OKLAHOMA

Okmulgee County

A zinc smelter is being constructed at Henryetta by the Picher Lead Co. of Joplin, Missouri. It will have 3200 retorts, and is to cost around $225,000.

SOUTH DAKOTA

Lawrence County

A site for a mill is being examined by the Oro Hondo company.

To treat the low-grade wolframite in its Golden Summit claim the Homestake company is to erect a concentrating plant. This will consist of 5 stamps, a Wilfley table, and Deister slime-table, able to treat 20 tons a day. The mill is expected to be ready late in May. The Golden Summit deposit is an arc-shaped flat body, 8 to 10 in. thick at the centre, tapering to the ends, the whole being 4 to 6 ft. wide. It is persistent.

The Columbia mine at Keystone was recently examined by R. Blackstone of the Homestake company.

Two weeks ago the Wasp No. 2 company dispatched tungsten ore and concentrate valued at nearly $100,000. The average per unit of 20 lb. was $82. Some of the ore contained 45%, and concentrate 63%.

Fluorite, used by steel and glass manufacturers, has advanced to $12 per ton, causing the Echo Mining Co. in the Maitland district to increase its operations.

UTAH

Juab County

The Colorado and Beck Tunnel companies are to be merged under the name of Colorado Consolidated Mining Co. The mines have produced $5,200,000 and $2,000,000, and paid $2,600,000 and $675,000 in dividends, respectively. The metals produced are lead, silver, copper, and gold.

Up to 60% manganese ore has been opened at 225 ft. in the Tintic Delmar mine.

MEXICO

The trouble in Mexico effected mineral shipments across the border of the United States during March; these consisted of ₱143,800 gold, ₱348,700 silver, and ₱1,857,500 copper. Nacozari sent 10,028 tons of copper ore and concentrate, and El Tigre 220 tons of silver concentrate and some cyanide bullion.

Hidalgo

Profit of Santa Gertrudis from 20,944 tons in February was $86,400.

PERSONAL

Note: The Editor invites members of the profession to send him particulars of their work and appointments. This information is of unquestioned interest to our readers.

John Ballot is at New York.

F. H. Hamilton is at Toronto.

F. O. Williamson of Chicago is in San Francisco.

Walter Strache has returned to New York from Brazil.

David T. Day of Washington, D. C., is at the Palace hotel.

Raul Madero is in New York; Julio Madero is in Jalisco.

W. B. Dennis has returned from New York to Carlton, Oregon.

Arthur W. Stevens is at Denver, on his way to Leadville and Ouray.

E. B. Thornhill has joined the staff of the Metals Recovery Co. at Cobalt.

Rex Taylor is manager at the Wettlaufer mine, South Lorrain, Cobalt.

Leo Von Rosenberg was in the Ray and Prescott districts, Arizona, recently.

A. H. Brown has resigned as manager of the Hudson Bay Mines, Ltd., at Cobalt.

F. H. Dakin, superintendent of the Gray Eagle copper mine, in Siskiyou county, is here.

G. A. Joslin has left the Ray Consolidated and is in Kansas City on professional business.

A. Freitag, superintendent for the Nevada Packard Mines Co. has returned to Rochester, Nevada.

Wallace E. Pratt has resigned from the Philippine Mines Department to engage in private practice.

Fred. G. Farish, manager for the Lluvia de Oro Mining Co., is living for the present at San Diego, California.

H. Foster Bain, editor of *The Mining Magazine*, is on his way to Johannesburg to study conditions on the Rand.

A. W. Oliver, cashier of the Eagle Ore company, has been appointed general manager. Karl V. Simpson succeeds Mr. Oliver at Cripple Creek.

Ed. C. Morse left for Alaska April 3 to resume charge of the 40-ton quartz mill of the Princeton Mining Co. at Dolomi, on Prince of Wales Island.

T. S. O'Brien, formerly general manager for the Original Amador Mines Co., has joined the staff of the Joshua Hendy Iron Works of San Francisco.

John F. Hayford, director of the engineering college of the Northwestern University, will deliver the address to the graduating class of the Michigan College of Mines.

J. W. Whitehurst has returned to San Francisco from Contra Estaca, Sinaloa, Mexico. He leaves for Salida, Colorado, where he will be for the next two months, after which he will return to Mexico.

George M. Taylor, general manager of the Portland Gold Mining Co.'s mills at Cripple Creek and Colorado Springs, recently gave an address on tungsten before the Chamber of Commerce at the latter place.

Frank A. Ross of Spokane was honored at the recent inauguration of Dr. Ernest O. Holland as President of the State College of Washington, by having conferred upon him the degree of Master of Science in engineering "in recognition of his service to the mining industry of the great West."

W. S. Holloway has been awarded the military cross for conspicuous gallantry during mining operations. The official notification says: "Whilst endeavoring to rescue an officer who had been incapacitated he was buried by a fall of earth and timber. He succeeded in extricating himself, and eventually reached and dragged the incapacitated officer to a place of safety." Mr. Holloway was in charge of the Gwendoline mine in Korea for Jardine Matheson & Co., and is serving as lieutenant with a tunnelling company of the Royal Engineers.

THE METAL MARKET

METAL PRICES

San Francisco, April 11.

Antimony, cents per pound	44
Electrolytic copper, cents per pound	29
Pig lead, cents per pound	8.00—8.80
Platinum: soft metal, per ounce	$88
Platinum: hard metal, 10% iridium, per ounce	$92
Quicksilver, per flask of 75 lb	$152
Spelter, cents per pound	22
Tin, cents per pound	46
Zinc-dust, cents per pound	30

It is semi-officially announced in Petrograd that the Russian government's proposed monopoly of platinum will not take effect. Russia produces 93% of the world's total.

ORE PRICES

San Francisco, April 11.

Antimony: 50% product, per unit, of 1%, or 20 lb	$2.25
Chrome, 40% and over, f.o.b. cars California, per ton	12.50
Magnesite: crude, per ton, f.o.b.	8.00
Magnesite: plastic, no iron and lime, calcined, ton	25.00—30.00
Magnesite: refractory, 11% iron, dead-burned, ton	35.00
Manganese: 50% metal, 8% silica, per ton	12.00
Tungsten: 60% WO_3 per unit of 20 lb	65.00—75.00
Vanadium: 10% vanadic oxide, per lb	0.50

A 10% premium is being paid on the $75 per unit schedule by the principal tungsten buyers at Boulder, Colorado.

Wolframite of various grades from the Wasp No. 2 mine, South Dakota, recently averaged $82 per unit; the total was nearly $100,000.

New York, April 5.

Antimony: 50 to 100-ton lots, forward price per unit, $2.60.

EASTERN METAL MARKET

(By wire from New York.)

April 11.—Export sales caused advances in copper; lead is dull; spelter is strong, though less active.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending	
Apr.	5	61.62	Mch. 1	56.79

Tin is strong at 55 cents.

Antimony is firm at 45c. for Oriental metal, duty paid.

Aluminum is unchanged at 59 to 60 cents.

Eastern Metal Market

New York, April 5.

During the past few days there has been a heavy business in copper for export. Great Britain and France have been the big buyers, and Russia also is expected to become active. Estimates place the amount taken at 100,000,000 lb. Practically all of the purchasing was for war purposes. The market advanced with the movement, and from 26.87 to 27.50c. was paid for large lots for June, July, and August shipment. The quotation for lead was sagging a week ago, but it braced-up as a result of the action of the A. S. & R. Co. in advancing its price $10 per ton on March 30. Independents again are asking 8c. at both New York and St. Louis. Zinc is moderately active, prices are a little stronger, and greater activity is looked for. April delivery tin is tightly held because of the continued difficulty in getting licenses to ship from London. The A. S. & R. Co. announces that it is ready to supply small quantities of domestic refined tin for experimental purposes, after which it will consider contracts at prices based on average quotations. Antimony and aluminum are unchanged.

The pig-iron production in March was 3,337,691 tons, or 107,667 tons a day, against 3,087,212 tons in February, equal to 106,456 tons daily. It thus will be seen that it is now being produced at a rate equal to 40,000,000 tons yearly, while steel ingots are made at 43,000,000 to 44,000,000 tons a year.

COPPER

Since March 28 an enormous business has been done in electrolytic copper for June, July, and August delivery, at prices ranging from 26.87 up to 27.50c., although the lower price may have been shaded a little in view of the great quantity taken. The purchasing was done by the British and French governments, and it is not thought to be ended, as Russia is expected to come in the market. It is estimated (and the figure is purely an estimate) that 100,000,000 lb. of copper was taken. A good business was done on future positions of Lake also. Domestic consumers did not figure in the buying nearly as much as was expected; in fact, the demand for ordinary and peaceful purposes is commonplace. The big business was war business. In its early stages the buying was conducted very quietly, and the magnitude of the movement was not apparent until it was well under way. Deals were closed singly with the larger producers, the activity being especially notable on March 29. The business continued into this month, despite advancing prices, and April 3 the market closed strong at 27.50c., 30 days, delivered, at which price large sales were made. On the 4th a good business was done also, and electrolytic was almost unobtainable at 27.50c., 30 days, delivered, some of the sellers asserting that they were sold-up to August. Prompt copper is not plentiful, but can be had at about ½ premium over the price for June, July, and August, but the market so far as business goes is in futures. Lake is nominal at 27.50c., cash, New York. European statistics show that British and French stocks are steadily dwindling. March exports totaled 24,006 tons.

ZINC

In view of the heavy buying of copper the zinc trade is optimistic, and thinks that a correspondingly large movement in its metal is not far off. As it is, there has been a steady, if moderate, demand for April and May spelter for several days, and the market has a decidedly better tone. Producers do not think that the smelting of zinc in Great Britain, even with Government assistance, will cut much of a figure for some time to come, in view of present difficulties. The scarcity of ships and the hindrance to shipping constitute a great obstruction to getting a sufficient supply of ore from Australia or elsewhere. Great Britain, however, after the War, will be in a position to take some of the spelter business heretofore enjoyed by Germany. It is also considered that the greatly increased production in this country will be absorbed. The domestic brass mills have not been buying as heavily as they did a few months ago, for the reason that they have not had as many or as large contracts to cover as they had earlier in the War. The galvanizing trade continues to operate considerably below normal, but galvanized products are practically an indispensable product and it must buy, at least on the dips of the market. The New York price yesterday (April 4) was 18c., and that at East St. Louis 17.75c., for prompt, while April was held at about 17.75c. New York, May at 17.75c., and June at 16.75c. The London quotation on April 4 was £91, a decline of £2 from the previous day. March exports were 1705 tons.

LEAD

The situation in lead has continued interesting. The A. S. & R. Co. gave the trade a jolt. Its statement, to which reference was made in last week's notes, created the impression that it did not countenance and would not support war prices; as a result the quotations of independent sellers sagged to 7.87c., New York. On the morning of Thursday, March 30, lead was offered at 7.75c. East St. Louis. About noon on that day the A. S. & R. Co., announced an advance of $10 per ton, making its New York price 7.50c., thereby stiffening the market, and sending the outside price back to 8c., both at New York and St. Louis. In fact, March 31 business was done for domestic delivery on the basis of 8.25c., Chicago. It was believed, prior to the advance, that the prices of the leading producer and the independents were drawing together and that the abnormal condition would not last much longer. Some of the trade is inclined to view the company's action rather bitterly, saying that a part of the time when it was opposing high prices it was not selling at all, but that it was ready to sell on a higher price, when it learned through its superior European connections that foreign buying was about to be resumed. This week there has been an excellent demand from abroad. The A. S. & R. Co. might argue in the face of criticism that it said nothing about protecting foreign war consumers. On the other hand A. S. & R. Co. domestic consumers will have to pay a higher price also, in view of the fact that settlements are made on the average of its daily quotations. The New York quotation of independent producers is now 8c., and that at St. Louis is 8c., also. The A. S. & R. Co. St. Louis quotation is 7.42½c. Exports in March amounted to 4151 tons.

TIN

Of great importance in this metal is the statement of the A. S. & R. Co. that it is now ready to supply consumers with tin smelted from Bolivian ores at its new plant at Perth Amboy, N. J. This tin has been successfully used in tinning copperplates, and it is hoped that it will be acceptable to makers of tin-plate. It is proposed to dispose of the tin at a price based on average quotations. It is expected to be 99.80 to 99.90% fine. During April the company will supply small quantities for experimental purposes. There is a big demand for April tin, but sellers are few because of the continued difficulty experienced in getting licenses to ship from London. Tin in London, but with delivery in New York not guaranteed, is unsalable at 1½c. under what can be obtained for April shipments. The New York quotation for spot yesterday was 50.62½c. Despite all the scares in March the deliveries in that month reached the excellent total of 4726 tons, of which 2126 came *via* Pacific ports. In stock and landing on March 31 was 2746 tons. The quantity afloat on April 4 was 5149 tons.

COMPANY REPORTS

NEVADA HILLS MINING CO.

This company operates in Churchill county, Nevada, and the report of the general manager, E. A. Julian, covers 1915. Development totaled 1812 ft., costing $11,187, a much less footage than in 1914. The life of the mine is limited. Leasing will be reverted to when it is decided to close. Work was not very encouraging.

The mill treated 64,030 tons of ore and some tailing, averaging $5.58 per ton, with 81.7% recovery, a decrease of 7%, but this was planned deliberately, and was not really a loss, other things being considered. Costs recently were $3.50 per ton for all departments. The net profit was $39,142. An option has been taken on the Oro Fino mine in Esmeralda county.

BARNES-KING DEVELOPMENT CO.

The report of George T. M'Gee, manager of the Barnes-King Development Co., covers 1915. Mining and treatment continued throughout the year at the North Moccasin mine. To end litigation the Kendall property of 266 acres was purchased for $100,000, on terms. Over 6000 ft. of development was done in the North Moccasin. To treat some unoxidized ore, a roasting furnace was erected to prepare it for cyaniding. The mill treated 47,038 tons of ore averaging $9.80 per ton, with 89.7% recovery. Cyanide consumption was 0.4 lb., lime, 4.03 lb., and zinc, 0.43 lb. per ton. The roasted ore extraction was 81.3%, and cyanide and lime consumption 1.3 lb. and 21.5 lb. respectively. At the Piegon-Gloster mine a great deal of construction and development was done. The Norman adit was driven 900 ft., with a 124-ft. raise at the end. The mill treated 14,956 tons of $7.34 ore, with 85.2% recovery. The Shannon mine was taken under option for $228,000, on terms. The Gloster mill is to be re-modeled at a cost of $35,000 to treat Shannon ore. The year's profit was $147,968. A dividend was recently paid.

A 300-ton daily capacity aerial tram, 2½ miles long, from the Shannon mine to the Piegon-Gloster mill, is to be erected by the Riblet Tramway Co. for the Barnes-King Development company.

NORTH STAR MINES CO.

Improvements costing $100,412, and a threatened suit with the Empire company over extra-lateral rights were prominent tures of this Grass Valley, California, company's operations a 1915. Construction included a head-frame, hoist, bins, and sorting plant at the Central shaft. Late in 1914, at 6225 ft. on the incline, the North Star shaft cut a vein with a south-west dip, a dip almost the reverse direction from the North Star vein. The adjoining company later on claimed the apex of this vein, and serious litigation was averted by arranging boundaries. The vein will be a large producer in the near future. This suit and new plant have been described in this journal recently.

Development covered 9988 ft. The orebody at 3400 ft. was further opened, indicating a considerable quantity of fair ore. Work on the North Star vein at 5600 and 6000 ft. east has failed to find the downward extension of the good lodes at 5000 and 5300 ft. Although 5529 ft. of work was done in the Champion mine, no shoot of importance was discovered above the 2400-ft. level; results were disappointing.

From stopes above the 3400, 4000, and 4400-ft. levels of the North Star mine there was extracted 117,906 tons, of which 8046 tons was sorted as waste. The mill treated 109,860 tons, averaging $9.92 per ton, at a cost of $5.74 per ton treated. Mining cost $2.822, and development 88.2c. per ton mined, while milling and cyaniding cost 47.8 and 35.8c. per ton treated respectively. The Champion mine yielded $205,334 from 38,350 tons.

The recovery of precious metals was 97.4%, amalgamation saving 80.37, and cyanidation 19.63% of the total recovered.

The year's revenue was $1,295,084 from gold produced. Dividends totaled $250,000, four equal to 10% on the capital.

The results to date are 1,358,394 tons, averaging $12.846, giving a total of $17,450,527, of which $4,787,040 was paid in dividends.

AMERICAN SMELTING & REFINING CO.

An editorial in the Press of April 1 commented briefly on the results of this great concern; the following notes give more details of operations in 1915:

Earnings of the various properties after deducting expenses, etc., show an increase of $5,130,505 above those of 1914, and totaled $16,242,420. Earnings during the first half were $6,002,395, for the second half $10,455,195. From this was deducted $1,839,687 for depreciation and depletion of ore reserves, $795,000 for employees' bonuses and welfare work, and $554,429 for re-valuation of investments, etc. Of the balance of $13,053,305, the preferred shareholders received $6,001,844, and common shareholders $2,001,080, leaving $5,050,381 to be carried to profit and loss account. Expenditure on purchase of property and mines, also construction, was nearly $4,000,000. During 1916 this outlay will be at least $5,000,000. Mexican properties generally were unproductive and unprofitable. Work at the mines and smelters was very irregular. The plants were kept in good order. Profits of the new zinc plants in Colorado, Oklahoma, and Utah were satisfactory. The value of metals on hand in process amounts to $35,000,000. Cash in bank at the end of 1915 totaled $18,642,460. Employees received earnest consideration, especially in welfare work, safety, and education.

Some statistics of the past two years are as follows:

	1915	1914
Men employed (excluding Mexico)	15,556	12,179
Wages and salaries paid (excluding Mexico)	$11,392,503	$10,212,591
Average wages per employee per 8-hr. day	$2.44	$2.33
Ore mined, tons	1,578,611	1,266,702
Coal mined, tons	214,822	257,942
Charge smelted, tons	4,153,092	4,171,258
Bullion refined, tons	579,080	588,718
Coke produced, tons	120,660	129,650
Coal used, tons	604,204	544,619
Coke used, tons	401,511	447,761
Oil used, bbl.	829,304	976,528
Gold refined, ounces	2,672,702	2,540,911
Silver refined, ounces	76,117,453	77,604,483
Lead refined, tons	296,986	316,591
Copper refined, pounds	551,798,000	529,686,000
Metal products manufactured, pounds	37,835,899	40,122,817
Zinc refined, pounds	36,154,000	15,748,000
Acid, pounds	34,124,000	24,234,000
Nickel, pounds	1,120,556	356,187
Income:		
Gold	$55,239,405	$52,515,549
Silver	38,007,727	42,690,226
Lead	27,279,350	24,551,632
Copper	89,027,089	71,712,527
Other metals	6,105,291	2,431,410
Value of products of company's mines	3,820,166	3,135,809
Value of manufactured products	3,507,276	2,665,958
Miscellaneous income	1,791,511	1,222,514
Total of year's business	$224,777,815	$200,925,625
Net profit available for dividends	$13,053,304	$9,031,565
Net profit to volume of business per cent	5.807	4.494

Prospects of the company in Mexico are not bright.

BOOK REVIEWS

The Mechanical World Electrical Pocket Book for 1916. P. 240. Ill., index. The Norman-Remington Co., Baltimore. For sale by Mining and Scientific Press. Price, 25 cents.

This is the companion volume to the mechanical pocket book which was reviewed in the March 25, 1916, issue of this journal. The two books are similar and contain a large amount of valuable information in their respective lines. They are perhaps not quite so useful to Americans as they are to British engineers, but in either case, the purchaser need have no fear of failing to get his money's worth. A diary for 1916 is included in the volume.

Industrial Leadership. By H. L. Gantt. P. 128. Ill. Yale University Press, New Haven, 1916. For sale by Mining and Scientific Press. Price, $1.

The five lectures comprising this book were heard by the senior class of the Sheffield Scientific School in 1915. The methods of industrial leadership are based on the system of scientific management evolved by Taylor, with whom the author was a co-worker; the chief doctrine of this school is that efficient management of labor increases profits and wages.

A novel point brought out is that an impartial study of the Lawrence strike showed that the labor leaders had a much better understanding of the problems involved than the employers, and that no permanent industrial peace can be hoped for until the employers are better educated. The great profits of the Ford automobile are held to disprove the old theory that great profit can only be had by high prices. A fault of the book is the failure to consider the strenuous objections of the trade unions to scientific management.

Reinforced Concrete Construction. By George A. Hool. Vol. III. Bridges and Culverts. P. 684. Ill., index. McGraw-Hill Book Co., Inc., New York. For sale by Mining and Scientific Press. Price, $5.

This is probably the most comprehensive and useful treatise in English that has appeared upon the subject. Part I deals with the arch bridge. The calculation of stresses by the theory of elasticity is explained, together with the use of both influence lines and the ellipse of elasticity. Particular cases such as the design of unsymmetrical arches and those with elastic piers are discussed. Chapters are devoted to details of arch bridges and to construction of arch bridges. The design of the three-hinged arch by both the usual and the influence-line method is explained. The chapter devoted to patents is particularly useful in view of the number of patents which interfere with the free use of results of research in this field of engineering design. A large number of typical designs of arch bridges and details are then given. Part II is devoted to slab and girder bridges and includes chapters on slab bridges, simple and continuous-girder bridges, and cantilever bridges. Another chapter deals with the use of reinforced concrete in the construction of piers and of solid floors in ordinary steel-bridge construction. Part III discusses culverts, separate chapters being devoted to the calculation of the proper waterway for a given drainage area, and to pipe, box, and arch culverts. The rest of the book is contributed by other authors and concerns particular portions of the subject with which they were especially qualified to deal. Thus A. W. Ransome, a concrete-machinery manufacturer, contributes some valuable data on construction plant. L. H. Allen, connected with a construction company, discusses estimating. W. J. Titus considers the subject of artistic design. A. M. Wolf, a constructing engineer, describes in detail the methods of construction of several large reinforced concrete bridges.

RECENT PUBLICATIONS

Light Oil Fields of Wyoming. By L. W. Trumbull. Bulletin No. 12. P. 8. Map. Cheyenne, 1916.

Eighth Annual Report of the Geological Survey branch of the Department of Mines, New Zealand. P. 52. Illustrated. Wellington, 1915.

Petroleum Resources of the United States. By Ralph Arnold. Reprint from *Economic Geology*. P. 18. Illustrated. The estimated supply is 5,763,100,000 barrels.

Loblolly or North Carolina Pine. By W. W. Ashe. Forest inspector. P. 176. Illustrated. Bulletin 24. North Carolina Geological and Economic Survey Raleigh, 1915.

An excellent description of a useful wood.

Seventeenth Annual Report of the mining industry of Idaho for 1915. By Robert N. Bell, State inspector of mines. P. 134. Illustrated. Boise, 1916.

A résumé appeared in the Press of March 18.

Quarry Materials of New York—Granite, Gneiss, Trap, and Marble. By D. H. Newland. P. 212. Ill., index. New York State Museum Bulletin. Albany, 1916.

In 1913 the total value of the above rocks was $6,763,054.

Summary of Railway Returns for the fiscal year ended June 30, 1915. P. 23. Bureau of Railway Economics, Washington, D. C., 1916.

Contains summarized statistics of railroads in the United States.

Lewis and Gilmer Counties, West Virginia. By David B. Reger. P. 660. Ill., maps, index. West Virginia Geological Survey. Morgantown, 1916.

Mineral deposits of the region consist largely of oil, gas, and coal, also clay, shale, and sandstone. Some large gas-wells have been found in Lewis county. A great deal of work has been done in compiling this publication.

University of California, 1916:

The Owl Remains from Rancho La Brea. By Loye Holmes Miller. P. 8. Illustrated.

Notes on the Capromeryx Material from the Pleistocene of Rancho La Brea. By Asa C. Chandler. P. 10. Illustrated.

Corals from the Cretaceous and Tertiary of California and Oregon. By Jorgen O. Nomland. P. 18. Illustrated.

Relation of the Invertebrate to the Vertebrate Faunal Zones of the Jacalitos and Etchegoin Formations in the North Coalinga Region, California. By Jorgen O. Nomland. P. 12. Illustrated.

The Stratigraphy of the Pennsylvanian Series in Missouri. By Henry Hinds and F. C. Greene. With a chapter on Invertebrate Paleontology, by G. H. Girty. Vol. XIII, second series, Missouri Bureau of Geology and Mines. P. 407. Ill., map, charts, index. Rolla, 1915.

This report supplements volume XI, which mostly dealt with the coal deposits, and covers the formations that contain little or no coal. The Pennsylvanian series occurs in the north-west part of the State. In the field-work the various limestones were traced, where possible, across the State from Kansas to Iowa, and correlations made with those States, most of them being adopted by the neighboring States. A great deal of interesting information is included in this publication.

INDUSTRIAL NOTES

Improvements in Shoveling

Managers who operate their mines or mills on an efficiency basis have given considerable thought to shoveling. At first this would seem too paltry an operation to be systematized, as, indeed, it has appeared to many. But Frederick W. Taylor, conducting experiments at the plant of the Bethlehem Steel Co., was actually able to produce a tangible saving in shoveling costs of $36,417.69 in one year. This was effected by giving the men shovels that would hold a load of exactly 21 lb., different types of shovels being used for materials of different weights, since the 21-lb. load shovel was found to handle a maximum yardage with minimum effort for the shoveler. Such shovels have since come into wide use in mines, their efficiency having been established beyond question.

THE WYOMING SHOVEL.

CUTTING EDGE OF SHOVEL.

A still later development has been effected through making the shovel's digging-edge of chrome-nickel steel which, obviously, lengthens the life to an appreciable extent and also does away with bending the edge through contact with hard material. The steel wears down to a thin edge without being otherwise affected. Such a shovel is illustrated herewith. It holds a 21-lb. load, its edge is of nickel-steel, and it is known as the 'Wyoming-Mayari Red-edge Shovel,' manufactured by the Wyoming Shovel Works, Wyoming, Pennsylvania. For the Pacific Coast, Harron, Rickard & McCone, San Francisco, are the selling agents.

Personnel of THE DORR COMPANY successors to the Dorr Cyanide Machinery Co., is as follows: John V. N. Dorr, president, was educated as a chemist and after several years in industrial chemical research, including two years spent in the laboratory of Thomas A. Edison, came West and engaged in metallurgical work. He obtained his cyanide experience largely in the Black Hills, South Dakota, where after a period as chemist he leased and operated a custom cyanide plant under the firm name of Lundberg & Dorr, and later erected and operated the first plant (The Lundberg, Dorr & Wilson mill) to use the Moore filter. In this mill the Dorr classifier was developed. He later devised the Dorr thickener in the Mogul mill while acting as consulting engineer to that company. A. L. Blomfield, consulting engineer to the company, is a graduate of Melbourne University. After a number of years with Bewick, Moreing & Co. as metallurgist, having charge of several mills in Australia, he came to the United States and for eight years was superintendent of the Golden Cycle mill at Colorado Springs. The mechanical engineering staff of the Dorr Company has at its head W. A. Neill, who, for the previous 11 years was chief engineer of the mining department of the Allis-Chalmers Mfg. Co. In that capacity he had broad experience in designing cyanide and concentration mills, mine hoists, and various special machines. H. S. Coe, a Stanford University man with some 12 years' experience in mine examination and mill-work in Mexico, Korea, and Central America, has charge of the laboratory and research department. P. M. McHugh, a Colorado School of Mines engineer, has been associated with the Dorr Cyanide Machinery Co for the last 5 years and will act as metallurgical sales manager. H. N. Spicer, formerly with Bewick, Moreing & Co., will continue in charge of industrial work at New York. Wm. Russell, metallurgist, formerly with the McArthur-Forrest Co., who has been in charge of the London office since it was started, will continue there.

Bulletin No. 9 of the L. C. TRENT ENGINEERING CO., Los Angeles, deals with its 'Universal' cyaniding machine, which will collect and thicken a charge and afterward agitate the same charge; or will thicken and agitate in the same tank simultaneously; or will decant, clarify, and replace water with solution or solution with water; or will perform any action necessary to accomplish the complete treatment of mixed sand and slime, or slime alone, which are agitated simultaneously and so efficiently that the sand in the charge is treated in one-fourth the time required for leaching.

Bulletin 1417A of the ALLIS-CHALMERS MANUFACTURING CO. is of interest to smelting men, as it deals with furnaces and accessory equipment. Small copper and lead furnaces for remote districts and small mines are made when ordered; also up to the 44 by 180-in. water-jacketed blast-furnace for lead ore, and 48 by 192-in. for copper ore. Some useful notes, illustrated by plans and photographs, cover tuyeres, steel jackets, molds, slag-pots, settlers, charging-barrows, dump-cars, and blowers.

The AMERICAN MANGANESE STEEL CO. of Chicago has for distribution the following bulletins: No. 52, 'The Komata Liner for Pebble and Ball Mills;' No. 56-A, 'Crusher Wearing Parts for Jaw-Crushers;' No. 63, 'Amsco Manganese Steel Chain and Sprockets—All Types;' and No. 65, 'Missabe Manganese-Steel Dippers and Vanderhoef Fronts,' also 'Repair-Parts for Steam-Shovels and Dipper Dredges.'

An excellent booklet has been published by the UNION CONSTRUCTION CO., San Francisco, describing the construction and operation of the company's churn-drills for placer prospecting. A notable feature of the Union drill is the ease with which it can be knocked-down when necessary and transported by mules.

A tungsten concentrating mill is to be erected by John T. Duncan of Boulder, Colorado, on his Black Prince property, two miles below Boulder Falls in Boulder canyon. The contract for the equipment has been given to the DENVER QUARTZ MILL & CRUSHER CO. The mill is expected to be in operation by June 1.

Additional evidence of the activity in the mining industry is furnished by the new equipment purchased in districts all over the country. During the past month the REDWOOD MANUFACTURERS CO., San Francisco, has supplied wood stave pipe, in varying sizes, to more than a dozen companies.

Four new magnesite kilns are being erected at Portersville by the JOSHUA HENDY CO. of San Francisco. These cost $6000 each without lining. Ten or twelve kilns have been erected during the past two months in this State.

The VANADIUM-ALLOYS STEEL CO. of Pittsburg has just issued two folders descriptive of its Vasco choice and Vasco non-shrinkable grades of tool-steel.

EDITORIAL

T. A. RICKARD, Editor

SILVER has risen to 64c. Prospects are good for a continued rise. The movement of troops from India has been accompanied by the transfer of silver coinage to Egypt and Mesopotamia.

IN its issue of April 1, the *Engineering and Mining Journal* publishes a concentration formula as something new. This formula was originated by Mr. Jesse Scobey, now at Pittsburg, and was published by us in our issue of September 21, 1901, with an appreciative editorial note.

ANOTHER big deal in copper is announced in New York. Our correspondent states that between 100,000 and 125,000 tons has been taken by the British and French governments for delivery over the remainder of this year and the early part of 1917. Further buying on behalf of the Russian and Italian governments is expected.

PACHUCA will win increased prominence by reason of the rich silver-bearing orebodies found on the 1400-ft. level of the Real del Monte mine, operated by the United States Smelting company. The ore is said to average $30 per ton and to represent $15,000,000. This part of Mexico has suffered but little direct injury during the period of misrule, although it has been difficult to maintain a supply of things necessary to mining operations on a large scale.

TRADE names disregard both dictionaries and family bibles. The title of the interesting article by Mr. F. H. Mason suggests a typographical error, for Mr. Ambrose Monell is sufficiently well known to our readers to ensure a quick detection of an error in the spelling of his name. Apparently the dropping of an 'l' was designed to make editors and proof-readers sit up and take notice. In any event this useful new alloy will serve to perpetuate the honorable name of a brilliant financier.

VILLA'S death may have been "greatly exaggerated"; at the time of this writing confirmation is lacking. Meanwhile the attack on American troops at Parral, in which some Carranzista soldiers participated, augurs ill. It will be a marvel if the punitive expedition returns to the border without further attack, provoking counter-attack and leading to larger operations. The issue is not in the hands of either President Wilson or General Carranza, but in that of an ignorant and emotional population, easily misled by military adventurers posing as patriots. On this side also the public is being fed daily with a vast mess of misinformation from the correspondents of a sensational press. Every morning we have two or three pages of flapdoodle. Never was journalism so pitifully inefficient and so flagrantly irresponsible. Our own local newspapers appear to be written by office-boys for chamber-maids.

FRANCE is taking a large part of our copper production. During the seven months ending on January 31, the shipments to that country amounted to 75,560 tons, as compared with 42,500 in the corresponding period of 1914. England took 43,488 tons, as compared with 66,608 tons in the seven months of 1914. Russia has increased from 1867 to 12,207 tons, while Holland, which formerly served as a door to Germany, has decreased from 15,082 tons to 1372 in the two periods specified. Italy's demand from American sources of supply remains steadily at about 4000 tons per month.

SENSE of proportion is essential in mining as in business in general. Merely for the sake of doing something, it is not advisable to over-do other things. Henry Ford's idea that nothing is impossible until it has been proved so, is excellent in many ways, yet continued exhibitions involving more energy than judgment may do more harm than good. It is true of some companies, as of some men, that their sustained success is directly due to what they persist in not doing. That busy type of man who is always fussing about things, some of which are not worth doing at all, is neither convincing nor effective. Exaggeration of trivialities is likely to turn an executive into an office-boy.

NEXT June, Messrs. H. C. Perkins and Hennen Jennings will join Mr. F. W. Bradley, president of the three mining companies operating at Treadwell, in a visit to Alaska, for the purpose of appraising the Alaska Treadwell, Alaska Mexican, and Alaska United mines preparatory to a consolidation of these three contiguous properties, which have long been under the same management. Owing to the increasing depth of the mines, the pitch of the orebodies, and the need shortly for sinking the central shaft, it becomes advisable to join the three properties in ownership as well as management. We congratulate the shareholders on the trio of engineers by whom the appraisal will be made.

PREPAREDNESS has been advanced a step by the selection of 250 engineers to co-operate in a survey of national resources available for military and naval pur-

poses. These representatives, of the five engineering societies will act for a total membership of 30,000 men. Among those nominated we note the following mining engineers: Arizona, John C. Greenway; Alaska, Philip R. Bradley; Colorado, D. W. Brunton and Thos. B. Stearns; Utah, Lafayette Hanchett; Idaho, Stanly A. Easton; Montana, E. P. Mathewson; Nevada, W. E. Trent; and Minnesota, Horace V. Winchell. In California the five nominated are Wynn Meredith, G. W. Dickie, Charles W. Merrill, A. H. Babcock, and Edmund O'Neill. All of these selections will find hearty public approval. The European war has shown the advisability of mobilizing the engineering talent of a country and utilizing its services both at the front and in the manufactory. The President and the Secretary of the Navy have shown a good deal of sagacity in this matter.

DISCUSSION this week includes a letter from Mr. Frank H. Probert, an experienced engineer, who has been lecturing recently before the School of Mining in the University of California. He endorses the opinion expressed by Mr. Mathewson as to the necessity for giving a broad training to mining students. To Mr. P. G. Beckett, the manager of the Old Dominion mine, in Arizona, we are indebted for many practical details concerning steel-sharpening, as compiled for him by the superintendent of the mine, Mr. I. H. Barkdoll. The present status of professional activity is the subject of a letter from Mr. Frank A. Ross, a public-spirited engineer who takes a prominent part in the mining affairs of Spokane. Among other matters, he touches upon the propriety of professors practising as engineers. To Mr. T. W. Gruetter, a studious metallurgist, we owe an interesting note on the treatment of antimonial gold ore, supplementing the data given by Mr. Mason in our previous issue. Finally, the Manitoba mining law is outlined and discussed by Mr. W. K. Harding, of Chicago. This should be read in connection with Mr. Franklin W. Smith's scholarly article on 'The Law of Mines' and our own criticism of legislation recently proposed in Congress.

LACK of shipping is becoming an increasingly serious factor in commerce. For instance, the freight on nitrate from Chile is now $30 per ton as against a normal rate of $5 to $6. Hawaiian sugar is being shipped to San Francisco for transport across the continent to New York by rail, simply because vessels can be most profitably employed in short voyages; otherwise direct shipment through the Panama Canal would be natural. The re-opening of the Canal last Saturday is a welcome event, but the frequent blocking of that short cut has caused merchants to feel uncertain considering traffic through the Isthmus, so that relief will not be felt at once. This will affect ore shipments, for instance, those of tin concentrate from Bolivia to the new smelter at Perth Amboy. Tin is now being produced there, and the American Smelting & Refining Company, owners of the plant, are distributing samples of an unusually pure metal. Their operations in Chile involve a large amount of freight; thus the Chuquicamata and Braden mines will require 160,000 tons of freight during the next two years. That gives a good idea of the bigness of the operations now in progress at those two copper mines. The Andes Exploration Company, controlled by the Anaconda Copper Mining Company, will also be erecting a large plant, making a further demand on shipping from New York. Such facts as these suggest the congestion of maritime traffic threatened by the withdrawal and destruction of shipping in consequence of the War.

COMMENT concerning the slowness with which the quotations of copper companies respond to the rise in the price of the metal is almost unnecessary. Of course, those who are well informed realize that the market is abnormal, so that any calculations of future profit on present prices are ridiculous. The buyer of stock should distinguish between gambling on that fact for a quick deal and buying shares to hold them as an investment. The price of copper on the latter basis is somewhere between 15 and 17 cents per pound, allowing for an enhancement of value in the coming years. Moreover, it should be known that the costs given in brokers' circulars are largely theatrical, for the low operating expense per ton just now is due largely to the magnified scale of working, the selection of better-grade ore, and the rejection of low-grade material on account of hurry. All this means eventual wastage and cost. In short, the showing made by the great enterprises exploiting disseminated copper in Arizona, Utah, and Nevada, for example, is not to be considered as a guide to those who are thinking of buying shares on an investment basis, that is, for income.

CANADIAN taxation of profits in excess of 7% applies to gold mines, which, the world over, are suffering from the fact that the War has caused the value of the material—labor, machinery, and supplies—used in mining to appreciate as measured in terms of the gold itself, which, being the standard of value, remains fixed. In short, gold has depreciated as measured in commodities. This is urged by Mr. F. H. Hamilton, a recognized financial authority, in an interesting article appearing in the March issue of *The Mining Magazine*. He suggests forcibly that the imposition of a tax on profits above 7% disregards the essential features of the business of exploiting a gold mine, which is a short-lived rapidly-wasting asset entailing a risk that calls for much more than a 7% return on the money involved in its purchase and equipment. In any case, the yield from such a tax will be small and the harm done to a stimulating industry will be great. To the British, and to their allies, it must be a source of satisfaction that 60% of the gold production of the world is obtained from their own dominions, and 8% from Russian territory. As 20% is won in the United States, there only remains 12% for the rest of the world, and of this the Austro-German dominions contribute only a fraction, the statistical record often crediting the relatively small yield from imported ores to domestic production, which is negligible. We do

not wonder, therefore, that any check on gold mining is denounced as a blunder. When the great accounting takes place, the fellow with the yellow stuff in his till will be best able to meet his obligations.

The Mining Law

We have received a copy of H. R. 12275, which is "a bill to revise, amend, and codify the sections of the Revised Statutes of the United States relating to the location of mining claims on the public domain, and for other purposes." This bill has been introduced in the lower house of Congress by Mr. M. D. Foster, chairman of the House Committee on Mines and Mining. He sends us a copy of the proposed enactment and asks us to comment upon it. Our contemporary in New York refers to the author of this legislative exhibit as Dr. Foster, from which we infer that he is a Doctor of Divinity, because the wording of the bill suggests the assumption that a special providence waits to protect the application of it in the big world outdoors. The text contains many typographical errors, for which there is no excuse in a document intended to be taken with the utmost seriousness. Apart from these blemishes, the phrasing is marked by such prolixity and lack of cohesion as promises plenty of scope for confusion, in the field and in the courts. If the existing law, which has become crystallized in practice through long years of laborious interpretation, is to be superseded, it should be replaced by one offering the minimum of ambiguity and the least opening for litigation. In this respect H. R. 12275 is radically defective.

The principal changes in the law are as follows: (1) Discovery of a vein or lode is to be no longer a primary condition. (2) Where no outcrop exists the prospector can make a temporary location, which holds good for one year, when he must peg a permanent claim. (3) He has the option between two kinds of claim: the present one, 1500 by 600 feet, carrying extra-lateral rights, or a new one, 2100 feet square, giving him no rights outside his surface lines extended vertically downward, but granting the choice of applying the full width of the claim on the dip of the lode. (4) Both the oblong claim, with its extra-lateral right, based, as formerly, on the possession of an apex, and the square claim, with no such right, are subject to the privilege of the owner of a prior oblong location to follow a vein or lode, outcropping on his claim, on its dip into the territory of an adjacent junior location. (5) But this privilege of the prior location is limited to the two years after the junior location has been made and during those two years the prior locator must either remove the ore to which he is entitled or he must establish the position of the vein or lode passing from his claim into that of his neighbor. (6) To do that, he is permitted to enter upon the surface of the junior location "and drill or explore by vertical openings, or enter the workings of such junior locator * * * to aid in making such survey and identification of his vein or lode."

It is not worth while to refer to other amendments of the existing statute. Those outlined will suffice to indicate the nature of the changes suggested. They bristle with possibilities of litigation in every other line. Mr. Franklin Smith says that the old law contained a Pandora's box of mischief; this is true equally of its proposed substitute. If the miner is to have a substitute for the law with which he has grown familiar, he is entitled to expect one that will not drive him first to a lawyer and then to a geological expert in order that he may learn what it means. Why don't these law-makers start with a few definitions, if for no other reason than to clarify their own minds before they undertake to guide others? Let them begin with defining "vein or lode" and then "outcrop." No committee incompetent to give such definitions should essay the task of preparing a legislative measure dealing with the subject. It has been stated that Mr. Foster obtained the assistance of engineers in the Bureau of Mines, but we are able to assert that the bill does not represent the ideas of the Bureau; it is the compilation of one man—a politician in a hurry. It has been prepared without the assistance of those best qualified, namely, those who have had experience in the ownership of, and the litigation over, mining property. Such experience was made available to members of the Committee on Mines and Mining, but like most politicians, they did not like experts able to tell them too much; they preferred to muddle through in their own unscientific way. They ignored the opinion of the mining community as expressed on various occasions, and particularly at the meeting organized by the Mining and Metallurgical Society at Washington last December, that opinion having crystallized into a resolution that any legislation to be of permanent benefit must be preceded by a systematic investigation by a commission chosen for this special purpose. A bill to create such a commission was introduced by Mr. E. T. Taylor, of Colorado, and killed by Mr. James Wickersham, of Alaska, as soon as it was introduced in the House, but the sincerity of the Alaskan representative was mercilessly exposed shortly afterward by the *Engineering and Mining Journal*—a public service, well done. Then the member for Illinois, Mr. Foster, introduced his blundering bill of 73 pages, while in the Senate, Mr. Reed Smoot presented a brief bill abolishing the extra-lateral right but ignoring that of discovery. Another effort is to be made by Mr. Thomas J. Walsh, senator from Montana, who is co-operating with the Mining and Metallurgical Society in an effort to introduce a piece of legislation more serviceable than the inchoate measures of the gentlemen from Illinois and Utah. The position has been complicated by the introduction of a leasing bill applicable to non-metalliferous deposits, such as coal, oil, and salines. This is disliked intensely in parts of the West but it is favored by the Administration and the passing of it is assumed in Mr. Foster's bill; see Section 2328a. The outlook is not good. A big problem is being tackled piecemeal, by legislative patchwork. In order to do justice to a complex subject and to perform a big task efficiently, it is advisable that the mining law be revised in connection with cognate laws affecting the entire sub-

ject of administering the public land. Perpetual tinkering, here and there, only makes for unrest, irritation, and confusion. As regards our mining regions, the harm has been done, the territory virgin to new legislation is circumscribed, most of the ore deposits have been covered, if not discovered, and the introduction of regulations based on a radically different principle will only be justified if it is the result of careful investigation and sagacious preparation. That description does not apply to H. R. 12275.

The Man Who Sits Back

You know him: he leans back in his chair, cocks his cigar at an aggressive angle from the corner of his mouth, looks supercilliously wise, and says nothing while you others are in the midst of an eager frank discussion. He knows all about it, you are given to understand, but he does not think it worth while to contribute from the wealth of his wisdom. That type of man crosses the trail of all of us who are keenly participating in technical progress and scientific research. If you mention the work done by somebody else, he tells you that he himself did the same thing long ago but did not care to rush into print. If you speak approvingly of another man's contribution to current knowledge, in the shape of an article or paper, he calls it 'piffle' and conveys the idea that if he were to tackle the subject something really worth while would result. If you suggest that he ought to do so, he retorts that he is too busy for such inconsequential labor, and he sits back in his chair with an access of self-complacency. He depreciates the work of others; he deprecates their willingness to add to the stock of experience by writing; he belittles their effort to advance the cause of technical progress by speaking at engineering meetings. All these provoke his disdain. And yet all the while he is only a four-flush, a simulacrum, for he does not know so very much, he could not write about it with any skill, nor could he stand on his feet and speak clearly for ten minutes at a stretch. He is a false alarm, and in time he is not only discovered: he discovers himself. Giving nothing, he receives none; not being co-operative, he is let alone. The insolence of an incommunicative self-detachment leaves him isolated on a little ragged reef of crumbling conceit. The great procession moves forward while he stands sneering in a darkening side-street. Those whom he discounted have won credit from their fellows; the men who gave freely from their little store of knowledge have garnered a rich harvest of scientific truth; the exchange of professional experience has brought mutual good and culminated in cordial co-operation, without which nothing really big can be done in this world. The man who used to sit back has taken a back seat for all time.

Avoid him, he is a bad oyster in the feast of life. Avoid his pestilential pose. We address ourselves to the younger men, for our contemporaries are their own philosophers. As a matter of fact, the man who sits back is no longer young; he never was; at an early period in his jaundiced life he lost the essential marks of youth—generosity, expansiveness, comradeship. His years may be few, but he is a shriveled miser who guards his little hoard while the lordly galleons go sailing past the nearby headland. The instinct of youth is to give and to exchange ungrudgingly. Have you ever thought how little of what you know is original—your own, as it were? Fully 95% of what we know has been given to us without payment: in books, in teachings, in talk with associates. The price of a book or the fee for a course of lessons we do not count as a *quid pro quo*, it is merely an honorarium such as you give the keeper of the king's treasure when he admits you to the vaults of the palace of knowledge. We are in debt for what we know and the debt is like the one we owe our mother, unpayable, never to be liquidated, save in making good use of the gift. Having been so freely enriched, it remains for us to give in turn to those that follow. Consider what metallurgy would be today if each man had worked like an alchemist in his cell or a conspirator in his cellar. Eliminate the clearing-house of ideas and man would be insolvent. The individual contribution is so small that by itself it is of little avail; single bricks that make no buildings until arranged in orderly fashion. Even as it is, with all the social impulses that lead to co-operation, it is probable that the world has lost much that it could ill spare through secrecy and the failure to record. We recall a mining engineer at Denver who died leaving a mass of notes, intelligible only to himself, with the confession that he had intended to arrange and systematize them some day. That day never came; another came instead. A fire such as that in San Francisco, ten years ago, destroyed whole libraries of knowledge, many not yet printed. One family of engineers is reported to have maintained a record of their own experiences for the use of their own family, but the flames swept it into smoke and they were bankrupt of their selfish gains. Bah! that sort of thing is meaner than the man who called on a sick friend and ate all his grapes. And it is so pitifully futile. The best way to gain information is to give it. Nobody learns as much from a book or an article as the man who wrote it. The effort to put a lot of amorphous notes into crystalline literary form is a mental discipline; it discloses the holes in the writer's information; it causes him to co-ordinate what he knows on the subject so that he himself cannot forget it easily. Otherwise it passes like smoke from a camp-fire. Consider the mines you visited or the mining districts you traversed ten years ago; how much do you remember about them that has technical value now? If you had written an article on them, for publication—and that use of writing is the only one to ensure care and finality—you would not only have arranged the bundles of impressions in portable shape, but you could now refresh your memory by the written word. So, we say to the young man, pay no attention to the man who sits back and sneers at the generous effort of others. Or, if you are curious, ask him to show you the fruits of his philosophy. In an earthen vessel on his mantel you will find them: Dead Sea apples, the apples of Sodom, bitter and dry.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Mining Education

The Editor:

Sir—Within the last five years the Royal School of Mines, London, the Colorado School of Mines, and Columbia University have had to fill the chairs of mining. The same problem now confronts two other technical colleges in this country. The responsibility of the executive committees having to make these appointments is great, and the personality, influence, and ability of the appointees will probably be reflected in the mining history of the next half century. Hence the subject of the early training of a mining engineer is deserving of deep thought and constructive discussion. The comment of Mr. E. P. Mathewson in your issue of April 8, and the editorial on this subject in the issue of March 11, confirm, in a general way, my own convictions, except that I would even more strongly emphasize the necessity for sound training in the keystone of all scholarship: the ability to read and write the English language. This should be taught in the grammar grades, continued in the high-school, cultivated and exercised in the mining colleges. On this solid foundation erect a framework of knowledge of the natural sciences, chemistry, physics, mechanics, and allied subjects; reinforce it with a study of business economics, then build up the superstructure by teaching the principles of mining in the class-room and by practical demonstrations and personal contact with actual operations in the field. Mining colleges at the best can only teach the alphabet of mining science, which the student will use in later life to spell success or failure. The instruction should be competent, but general rather than highly specialized.

In the school of riper experience, the student will coordinate his ideas and discriminate between that which is essential and that which is superfluous; he will drift unconsciously into a particular line of work as opportunity offers, but on leaving college his knowledge should be sufficiently broad to enable him to apply himself intelligently to any branch of the industry. The late Clement Le Neve Foster, addressing the graduate students at the Royal School of Mines, London, in 1896, said, in part: "Gentlemen: You have been trained during these three years in the principles of chemical, geological, mining, and allied science; you are filled with theories and saturated with technical terms. You have studied the sedimentaries, igneous, and metamorphic rocks; of mineralogy you have had enough. Just one last word; after all there are only two kinds of rocks which are of importance—ore and waste. The thing is to know the difference."

The old order of things changeth. With improved methods of treatment, the 'waste' of today may be the 'ore' of tomorrow and it is probable that the abandoned mines of the past will be the profitable mines of the future. This progress will be retarded unless the student has a good general working knowledge of all branches of the industry. His vision must be large and his mental attitude plastic. Had I a son to educate for the profession, I would wish that his early training be given in one of the old English schools, such as Eton, Harrow, or Rugby; to be continued in such an institution as the Michigan College of Mines, where efficient theoretical and practical instruction is given, spending his vacations at different mining centres in contact with men and methods; then a year or two in the field that he might find himself and the particular work for which he was best fitted, and later a post-graduate course at Columbia, Harvard, or some other first-class university, to round out his education or develop his specialty. Above all things, I would wish him to care for his body as well as his brain, to cultivate and maintain a manly relationship with his fellow-men. *Mens sana in corpore sano.*

We are living in the age of specialists, the general practitioner is *passé*. Individualism or specialization is to be encouraged, still I hold that the curriculum of a mining college should be broad in its scope; that mining students be trained in the essential sciences; that they be informed of all phases of current practice, and that they specialize in that greater university—the mining field.

Drill-Steel Sharpening at the Old Dominion Mine

The Editor:

Sir—Our mine superintendent, I. H. Barkdoll, has compiled the following notes on steel sharpening in answer to your enquiry. The drill-steel used by the Old Dominion Copper Mining & Smelting Co. is of four kinds: Leyner steel; piston-drill steel; stoper steel; and Jack-hammer steel. Leyner steel is made from 1¼ round, hollow Keystone bars. It is cut into four lengths, 2 ft. 9 in., 4 ft. 9 in., 6 ft. 9 in., and 8 ft. 9 in. Shanks and bits are made on a No. 5 mechanical sharpener, and ganging is done automatically when sharpening, only one

heat being taken for each shank or bit. The different gauges on the Leyner steel are 2½ in., 2¼ in., 2 in., and 1¾ in. Four-point cross bits are used, with shoulders ⅜ in. thick and cutting edge drawn to 90° pitch. Stoper steel is made from inch grooved Keystone steel cut into lengths of 2, 3, 4, 5, and 6 ft., with bits gauged 1⅞, 1⅝, 1½, 1⅜, and 1¼ inch. Jack-hammer steel is made from ⅞-in. hexagon hollow Keystone, cut into lengths 2, 3, 4, 5, and 6 ft. and ganged the same as the stoper steel; both the four and six-point bits are used, depending on the ground to be drilled.

Sharpening and tempering of all steel is by the same process. Hollow steel before heating is thoroughly cleaned and blown out by means of a steel tube attached to a spring-valve on the compressed-air line. A single heat is taken for the punching and sharpening operation, the bits being heated for 2½ in. in a quick fire. After heating, the hollow steel is punched in the centre by an air-punch (made from a No. 2 mechanical sharpener fitted with an air-cylinder punch), enlarging the hole sufficiently so that, when sharpened, it will not close. It then goes to the sharpener, where it is sharpened and ganged at one operation. Stoper and piston-drill steel are treated in the same manner except that a shorter heat is taken, as no punching is required, being all solid steel.

Piston-drill steel is made in the following manner. Starters are cut from 1⅞-in. Keystone grooved steel 2 ft. 4 in. long, with shanks drawn on one end to fit the drill-chuck. The 2nds, 3rds, 4ths, and 5ths are made by welding 1⅝, 1½, and 1¼-in. grooved steel, cut 2 ft. 4 in., on 1¼ hexagon steel, making the total lengths 4, 6, 8, and 10 ft. The gauges for this steel are 2⅝, 2⅜, 2⅛, 1⅞, and 1¾ in. These are also cross-bits, ⅝ in. thick at the shoulder, with the cutting edge drawn to 92° pitch. This steel is standard for all our types of piston-drills such as Sullivan, Wood, Holman, and Ingersoll-Rand 3-in. machines and does not prove too heavy for 2¾-in. and 2⅝-in. machines. This standardization of piston-drill steel is made possible by having the chuck-bushings in all machines standard, and allowing only one class of steel for each class of drill.

All tempering is done by re-heating, which hardens where hardness is required, while the remainder of the drill remains soft and tough. In tempering, after sharpening, with the same heat the drill is often hardened too far back and the bit is liable to break in hard ground. The tempering heat is as short as possible with an even slow fire to a cherry red, then dipped in pure water. The water is kept at an even temperature by having the intake-pipe at the bottom and the overflow on top, with the water in continuous circulation. In tempering shanks we heat about an inch of shank, dip, and draw to a light-straw color. Much depends, of course, on the class of steel used. Breakage on our steel averages ½% of the pieces used, or 3 in 600.

Is Mining Engineering on the Wane?

The Editor:

Sir—Your editorial of March 11, 1916, on this subject, is so clearly to the point and touches so nearly the future of independent, or unsalaried, engineers that it merits comment. Questions of this kind are apt to be received skeptically by some and ignored totally by others, particularly in technical circles, but the fact remains nevertheless that certain recent changes in business methods are reacting upon the professions in a manner that gives rise to grave concern and calls for earnest consideration by engineers of every class.

First of all comes a recognition of the fact that this is an age of transition in almost everything—in morals, religion, art, science, and, especially, in business; moreover, that changes such as are now in progress require fundamental readjustments of the plans, pursuits, and personal ambitions of those affected, namely, the independent or unsalaried engineers. But, inasmuch as the salaried engineer of today is certain to become, by the law of succession alone, the unsalaried engineer of the future, both may be classed as one for the purposes of this discussion, which, then, includes all engineers.

Your editorial is certainly right in maintaining that mining engineering, *per se*, is not on the wane and never will be while civilization exists; yet the business of independent consulting mining engineers shows unmistakable signs of a rapid decline. Both the editorial and the paper by Mr. Arthur L. Walker, which it quotes, attribute this decline, first, to the Mexican revolution, which turned loose upon the United States a small army of competent engineers and thereby glutted the market, so to speak; second, to the European war, which closed several important mining regions; third, to a prolonged financial stringency, which suppressed new enterprises and stopped those in progress; fourth, to a surplus of mining graduates who, by the way, usually work for practically nothing to gain experience; fifth, to the modern demand for specialists in every line.

Manifestly, all of these have been contributing causes, but they do not include the most important, direct and, perhaps, most permanent causes that threaten the business of independent engineers; in fact, all but the last two are of a temporary nature and may be neglected; even the present excessive output of mining graduates may automatically regulate itself in time, but the demand for specialists must continue to increase and the question then is; will these specialists themselves be able to maintain their independence in the face of the new conditions, which may be stated as follows: first, the consolidation of mining interests by which nearly all of our great camps have become dominated by single companies, each of them maintaining its own highly organized engineering staff and seldom employing outside talent; second, the gradual disappearance of the small development syndicate and its grubstaked prospector, due to this same consolidation movement. Just as the consolidated meat-packers have exterminated at once the village butcher and a thousand bidders in the open

cattle-markets, so this modern consolidation idea is banishing small mining operators from whom the independent engineer once realized much business and who numbered hundreds instead of dozens, as at present; third, and most important cause of all, perhaps, is the growing custom of furnishing public service through the medium of at least six different kinds of organized engineering talent of the highest order, namely, the staffs of our government bureaus, public utilities corporations, great mining companies, powerful exploration syndicates, mining machinery houses and, last but not least, our universities and colleges. Seldom does any one of these institutions, or corporations, throw business in the way of the independent engineer, but all of them take it from him; and in the case of universities and colleges especially the strange spectacle is frequently presented of the professor coming into direct and sometimes ruinous competition with his former students, thereby giving rise to much bitter complaint.

Personally, I defend the right of a professor to enter the field of public service, provided that his fees equal or exceed the highest obtainable by any established engineer operating independently in that field, in which case the question is reduced to a matter of relative ability. In other words, if the professor ranks so highly as an engineer that the client prefers to pay a premium for his services then that client certainly has a right to exercise that preference and the competition is justified as between man and man. Otherwise, the prestige, publicity, salary, student aid, and equipment facilities enjoyed by the professor give him so great and undue an advantage over the engineer in business for himself that the latter is practically eliminated from the competition, other things being equal.

These, then, are conditions that call for earnest consideration by the engineer both of today and tomorrow. He must anticipate the time when younger men will displace him and he must ask himself what he can then do for a living. Until quite recently every ambitious engineer has been warranted in dreaming of the day when, ripe in experience and with a reputation well earned, he may strike out for himself and accumulate a competency for old age such as no engineering salary is likely to supply; but what about such dreams in the future? Are they likely to be realized, or not? Are these dangers fancied, or real?

FRANK A. ROSS.

Spokane, March 20.

Antimonial Gold Ore

The Editor:

Sir—Referring to the remarks by Wm. Seward Mann on 'Treatment of Antimony Gold Ore' and your own notes on the same:

There is a cheap way of making this caustic soda, namely, by electrolysis of salt solution (NaCl). If, in such solution, the sulphides are made the cathode and a little phenol-phthalein indicator added, the usual discoloration for alkalinity will surround the sulphides while the current passes. Thickness of film of antimony, silica, or grease determines the kilowatts consumed, electric power being cheap near many mines. Hydrogen is also formed and will remove oxide coatings. Care must be taken to avoid mixing the hydrogen with the oxygen from anode, by using a porous diaphragm and carrying away the oxygen. Otherwise explosions might result such as probably blew up the submarine lately and the recent explosion in the chlorate plant at Niagara Falls.

My experience with electrolytic amalgamation has convinced me that metallurgists have overlooked a good thing. For example, I believe electrolysis of NaCl with Hg cathode could be applied to picking up the floured 'quick' from cinnabar ore. Also, electrolysis without mercury, for removing oil from flotation concentrate. As the NaCl electrolysis is a reversible action, it can be worked cheaply. By-products, such as chlorine for chlorinating, or bleaching-powder for chasing the enemy from our borders with gas could also be made. From 16 lb. $NaCl + H_2O$, 11 lb. caustic and 9.8 lb. chlorine can be produced per indicated horse-power day. These are Castner's figures from practical work. But I am afraid I am taking too much of your space.

T. W. GRUETTER.

Medford, Oregon, April 3.

Manitoba Mining Law

The Editor:

Sir—The Legislative Assembly of Manitoba, Canada, has recently assented to an Act that censors and controls the public offering of mining and other shares within the Province.

This Act is characteristic of the direct and efficient way with which Canadian law-makers define methods of procedure which must be followed within their jurisdiction. It would be well for our legislatures to consider the actions of our thorough-going neighbors to the North in the supervision of an industry which on account of its economic possibilities provides fruitful material for the operations of those mining promoters and stock-peddlers who show scanty regard for truth, reason, or good business.

Manitoba has done little mining. In 1915 she contributed less than 1% of Canada's mineral industry, but recent activity and promising discoveries have prompted her policy of preparedness. While over three-fifths of Manitoba's 252,000 square miles is not particularly adapted to agriculture, it is largely underlain by rocks of the Pre-Cambrian age with numerous occurrences of the Keewatin and Huronian which are conspicuous in the Sudbury nickel, Cobalt silver, and Porcupine gold districts of Ontario.

Prospecting is now under way on a considerable scale and as a direct result of gold discoveries in the Rice Lake district, initial development of a number of properties with satisfactory results and an earnest attempt on the part of both the Government and a majority of the developing interests co-operatively to suppress any possible 'blue sky' promoting, the Manitoba Sale of

Shares Act, as amended, now stands as a welcome monument to the advocates of fair play. Extracts hereinafter given are from Chapter 175 of the Revised Statutes of Manitoba, 1913, as amended by Chapter 105 of 1914 and Chapter 96 of 1916, copies of which may be obtained from the King's Printer for Manitoba, at Winnipeg, Canada.

With respect to developing mining companies, this Act provides that it is unlawful for any person or persons, corporation or company, or any agent acting on his, their, or its behalf, to sell or offer to sell, or to directly or indirectly attempt to sell, in the Province of Manitoba, any shares, stocks, bonds, or other securities of any corporation or company, syndicate or association of persons, incorporated or unincorporated, without first obtaining from the Public Utility Commissioner a certificate to the effect set forth in the Act and a license from such agent in the manner provided for. A fine of from $50 to $500 is imposed upon any person convicted of doing anything forbidden by the Act.

"It shall also be unlawful for any printer, publisher, newspaper proprietor, or other person hereafter to print, publish, or advertise in this Province, in any newspaper, magazine or other periodical printed and published in this Province, or otherwise in this Province issue, put forth or distribute, any advertisement, circular, letter or other document containing any offer to sell or solicitation to purchase any of such shares, bonds, stocks or other securities, unless the company, corporation, association or syndicate whose shares, stocks, bonds or other securities are so offered for sale shall have first obtained from the commissioner the certificate aforesaid."

The procedure to obtain permission to sell securities requires the filing, properly verified, of "a statement showing in full detail the plan upon which the company proposes to transact business; a copy of all contracts, bonds or other instruments which it proposes to make with or sell to its contributors; a statement which shall show the name and location of the company, corporation, syndicate or association, and an itemized account of its actual financial condition, and the amount of its property and liabilities, and such other information touching its affairs as the commissioner may require."

The Commissioner is authorized, upon examination of the required information:

"* * * if he finds that such company is solvent, that its articles of incorporation or association, its constitution and by-laws, its proposed plan of business and proposed contracts contain and provide for a fair, just and equitable plan for the transaction of business, and in his judgment promise a fair return on the shares, stocks, bonds and other securities by it or by such person offered for sale, the commissioner shall issue to such company or person a certificate reciting that such company has complied with the provisions of this Act, that detailed information in regard to the company and its securities is on file in the commissioner's office for public inspection and information, that such company is permitted to do business in this Province, and such certificate shall also recite in bold type that the commissioner in no wise recommends the securities to be offered for sale by such company." (Section 10.)

The following extracts have recently been enacted to bear particularly upon the present mining situation:

"For the purpose of facilitating commercial, industrial and mining undertakings in Manitoba, it is enacted that whenever it shall appear that a company, whose undertaking, being of the nature aforesaid, has not been developed and that it is therefore not known that a fair return is promised upon its shares, stocks, bonds or securities, so as to justify a certificate under section 10 of this Act, such company may apply for a special certificate in respect of shares, stocks, bonds or securities, and permitting the offer by the company to the public for purchase of shares, stocks, bonds or securities by the company.

"The commissioner shall grant such special certificate upon the company establishing to his satisfaction that the proceeds of all sales of the unissued stock of said company will be paid to an incorporated or licensed trust company, in Manitoba, or other trustee approved by the commissioner, less a deduction in his discretion for commission for the sale of such stock and reasonable expenses incident to the office management of the company advertising, and in trust to apply such net proceeds to the development or operation of the undertaking of the company only.

"Any shareholder may sell from time to time any of the shares held by him in any company which has obtained a special certificate as aforesaid, personally or through his agents or upon any stock exchange, and no sale or attempt to sell by any such individual shareholder, his agent or brokers, shall be an infraction of this Act."

"Certificates for shares offered for sale pursuant to the provisions of this section shall have conspicuously written or printed on the face of them the words 'development stock'."

Any company or person obtaining the Commissioner's certificate may appoint one or more agents who must obtain a license from the Commissioner. This license must be carried by the agent and produced by him to every person with whom he proposes or offers to do any such business, and is subject to revocation at any time for cause appearing to the Commissioner sufficient.

Semi-annual reports are required to be made to the Commissioner showing the detail business conditions of a company, and no amendments to the constitution or by-laws are operative until filed and approved. The Commissioner is given all powers necessary to investigate or correct the operations of a company at any time as may seem to him just and equitable.

W. K. Harding.

Chicago, April 3.

Potash production of Germany in 1915 amounted to 6,799,757 double hundred-weight (220 lb.), against 9,039,883 in 1914, and 11,103,694 in 1913.

Monel Metal

By F. H. Mason

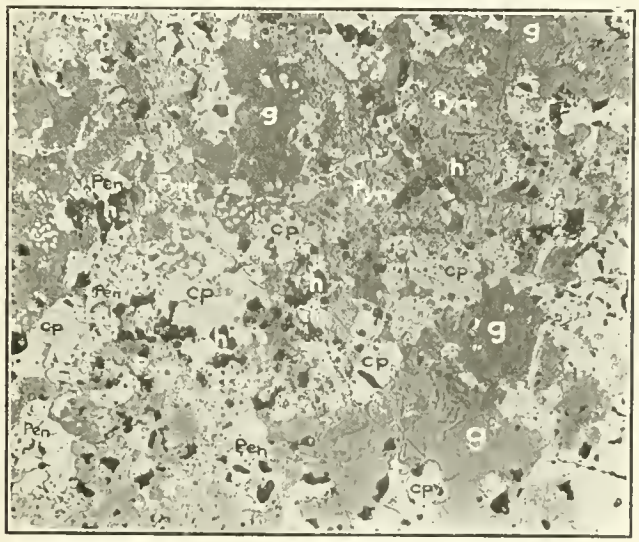
EVERYONE has heard the joke of the prospector who said he had discovered a brass mine. A brass mine, however, is a metallurgical, rather than a natural absurdity, for copper and zinc may occur together in nature in proportions suitable for the formation of brass, but, up to now, the metallurgist has not found a way of reducing them from their combinations to form that alloy. This is not the case with monel metal. Monel metal is an alloy, consisting of about 30% of copper and 70% of nickel—I shall deal with its exact composition later—and is reduced directly from the nickel-copper ores of Sudbury, Ontario.

Before dealing with monel metal, it might be well briefly to outline the methods by which nickel is extracted from the Sudbury ores, with the view to showing how much simpler it is to extract monel metal directly from the ore than first to extract the nickel and afterward alloy it with the desired proportion of copper. The direct reduction to monel metal has one serious disadvantage. The Sudbury ores sometimes contain appreciable quantities of the platinum group of minerals, which may be recovered from the residue from the Mond process, but which pass into the monel metal in the case of direct reduction to that alloy. On the other hand, the proportion of these precious metals is too small to affect the physical properties of monel metal, and likewise generally too small to pay the cost of the round-about method of first reducing to nickel when monel metal is the desired product.

The Sudbury nickel-copper ores consist essentially of pyrrhotite, with which is associated a number of nickel-bearing minerals, such as pentlandite (FeNiS), millerite (NiS), polydymite (Ni_4S_5), and rarely gersdorphite (NiSAs), and niccolite (NiAs), together with chalcopyrite and comparatively small amounts of silicious matter. Of course the composition of the ores varies in different mines and in different parts of the same mine, but for the purpose of this article the ores may be considered to contain about:

	%
Nickel	4.5
Copper	2.0
Iron	52.0
Sulphur	34.0
Insoluble	7.0

The ore is roasted in large heaps which, when well started with cord-wood, burn for three or four months, at the end of which time the sulphur content is reduced to 10 or 11%. The roasted ore is smelted in rectangular water-jacketed furnaces, together with green highly silicious ores, or, if the latter are not available, with silica. In this way much of the iron is fluxed off as silicate, more sulphur eliminated as dioxide, and a matte containing about 30% nickel-copper obtained. The furnace-matte is run into converters and blown to about 80% nickel-copper, silica being used as a flux. As the slag from this operation contains appreciable quantities of metal, it is returned to the blast-furnace. Up to now, this is as far as the metallurgy of nickel is carried at Sudbury. The Mond Nickel Co. ships the matte to Clydach, in South Wales, where it is subjected to that beautiful metallurgical process invented by Ludwig Mond, in which the nickel is converted into a gas at a temperature far below the boiling point of water; and the International Nickel Co. ships its matte to Bayonne, New Jersey, where some of it is reduced to nickel and some to monel metal.



MICRO-PHOTOGRAPH OF ORE FROM CREIGHTON MINE, SUDBURY.
g is gangue, feldspar, and hypersthene.
cp is chalcopyrite.
pen is pentlandite.
pyrr is pyrrhotite lightly fumed to give color contrast.
h is hole in surface.
Magnification, 19 diameters.

The process for the separation of nickel from copper at Bayonne is based on the fact that the sulphides of iron and copper are soluble in alkaline sulphides, while the sulphide of nickel is not appreciably soluble in these substances. The matte obtained from Sudbury is smelted in a reverberatory furnace with salt-cake and coke for a protracted period, during which the matte is stirred, from time to time, with green poles. The poling thoroughly mixes the substances, and the gases given off from the green wood help the coke in reducing the salt-cake to sulphide. When the process is considered to be complete, the matte is allowed to settle, the lighter sulphides

of iron and copper in solution in sodium sulphide tapped off first, and the heavier sulphide of nickel after. It generally takes at least two treatments to complete the separation. The nickel matte is then desulphurized, and the metal obtained.

At Clydach, the Sudbury matte is pulverized to 60-mesh, and roasted to oxide; it is then treated in vats with dilute sulphuric acid, at a temperature of 85° C., which dissolves about two-thirds of the copper oxide, the remainder being so protected by the nickel oxide, which is not appreciably soluble in the dilute acid, that further solution of the copper is prevented. The mixed oxides from this operation are filtered, dried centrifugally, and, without washing, placed on shelves in a tower, and reduced to metal by water-gas rich in hydrogen at a temperature of 250° C. When the reduction is complete the metals are transferred to another tower and subjected to the action of carbon monoxide at a temperature of 50°; the CO combines with nickel and forms carbonyl of nickel, and this gas is transferred to the decomposer, where it passes through granulated nickel at a temperature of 200°. At this temperature nickel corbonyl is decomposed into nickel and carbon monoxide, the nickel is deposited on the granules, which, of course, increase in size, and the CO is returned to the volatilizing-tower, where it combines with fresh nickel, which, in turn, is carried again to the decomposer. A point is reached in the volatilization somewhat similar to that which occurs in the sulphuric acid vats, only the reverse, where the copper forms a protective coat on the nickel, and prevents further attack from the CO; the residual metals are then re-oxidized by roasting, and returned to the sulphuric acid vats. Thus, it will be seen, there is a continual procession of the mixed metals from the roaster to the acid vats, then to the reducer, then to the volatilizer, and back again to the roaster. The final residue, insoluble in acid and unvolatilizable by CO, contains the platinum group of metals. A small quantity of nickel passes into the sulphuric acid, and is recovered by occasionally evaporating the mother liquor to dryness, igniting, and treating the residue as above.

It will be seen, then, that the processes in use for separating the nickel from the Sudbury matte are exceedingly complex. The International Nickel Co. refuses admission to its works, so that the exact method used by the company in producing monel metal, like that of producing nickel, is not known—the description in this article being taken from Ambrose Monell's patent specification—but the metallurgist will readily see that the blowing of the nickel-copper matte to blister and subsequent refining presents no serious difficulties, and is infinitely less intricate than the separation of nickel from nickel-copper matte by any known process.

Monel metal is silver-white, but assumes a blackish-gray cast on prolonged exposure to air. It is exceedingly ductile, can be rolled into thin sheets, and drawn into wire so fine that it resembles a silk thread; it resists acids, and, notwithstanding the change in color, appears to be unaffected by the atmospheres of coast and manufacturing cities. For these reasons, it makes an ideal roofing material, and can be used in infinitely finer sheets than is possible with copper.

Considerable range in composition of the metal is possible without appreciably affecting its physical properties. The composition varies as follows:

	%	
Nickel	68	to 72
Copper	27	to 32
Iron	0.5	to 1.5
Carbon	0.072	to 0.15
Sulphur	0.014	

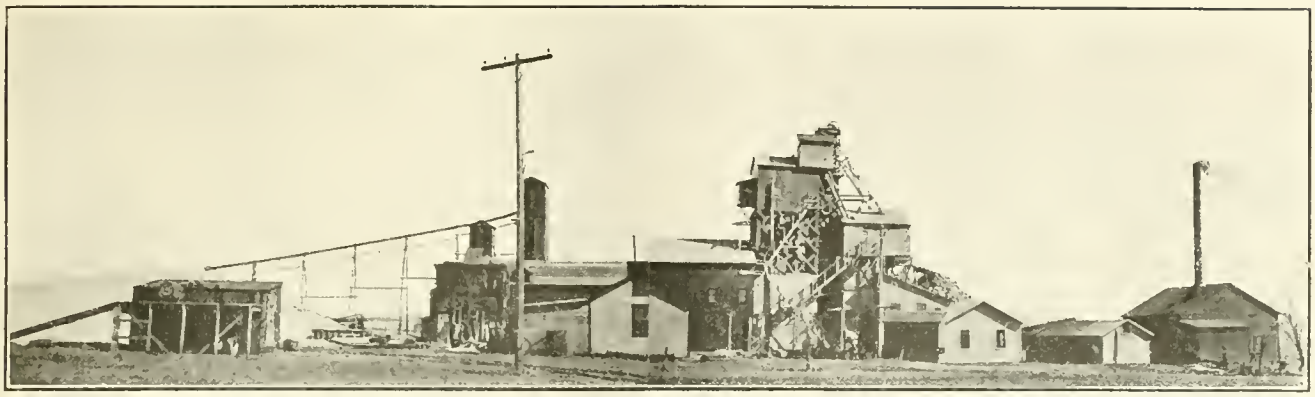
It melts at 1350° C., has an annealing temperature of 875° C., and can be rolled at temperatures between 900° and 1200°. A remarkable quality is that it retains 80% of its tensile strength at 555°, while ordinary steel retains only 7% at the same temperature.

The following are the results of physical tests:

	Hot-rolled rods.	Sand-cast rods
Elastic limit, pounds	58,873	37,427
Breaking strength, pounds	86,899	78,236
Elongation in 2 in., per cent	40	38
Reduction of area, per cent	60	34
Specific gravity	8.94 to 8.95	8.86 to 8.87

Modulus of elasticity, 22,000,000 to 23,000,000 pounds.
Electrical resistivity, 256 ohms per mil-foot.
Electrical conductivity, 4 when copper equals 100.
Thermal conductivity, 20 when copper equals 100.

It will be noticed, in looking at the analyses of the Sudbury ores, that they contain more iron than many ores that are smelted for the production of that metal, and if roasted they would be fairly rich iron ores. Some time ago, experiments were conducted under the auspices of the Mines Branch of the Canadian Department of Mines with a view to making nickel-steel directly from the Sudbury ores, and samples of the briquetted roasted ore and pig produced were on exhibit at the Canadian Pavilion at the P. P. I. E. But there the research appears to have ended, on account, I believe, of the copper, as well as the nickel, going into the pig. The slagging off of huge quantities of iron when nickel-steel is in so great demand seems wasteful, and, one would think, research should be stimulated with the view to making nickel-steel, like monel metal, direct from the ore. Nor, theoretically, would the problem seem to present insurmountable difficulties. Microscopic examinations have proved clearly that the nickel and the copper of the Sudbury ores occur independently of each other, so that the difficulty encountered in treating roasted matte with dilute sulphuric acid in the Mond process—that is, the protective coating of nickel oxide preventing part of the copper going into solution—would not be expected in leaching the roasted ore with sulphuric acid to remove the copper. If the copper could be removed in this way, it should be possible, one would think, to briquette and smelt the ore, or convert it into an iron-nickel sponge, and recover both iron and nickel in the operation. There are other methods of eliminating the copper and subsequently reducing the iron and nickel together, which will occur to the metallurgist.



WEST SIDE OF THOMPSON MILL.

Concentration of Zinc Ore in Wisconsin

By H. P. Wherry

WITHIN the last year two interesting articles have appeared on the mining and ore-dressing practice of the zinc mines in south-western Wisconsin.* At the time these were published the Thompson mine of the Field Mining & Milling Co., at New Diggings, was being made ready for operation. The methods adopted being distinctly different from any in the district, it is the object of this paper to discuss them in relation to the established practice as described in the two papers mentioned.

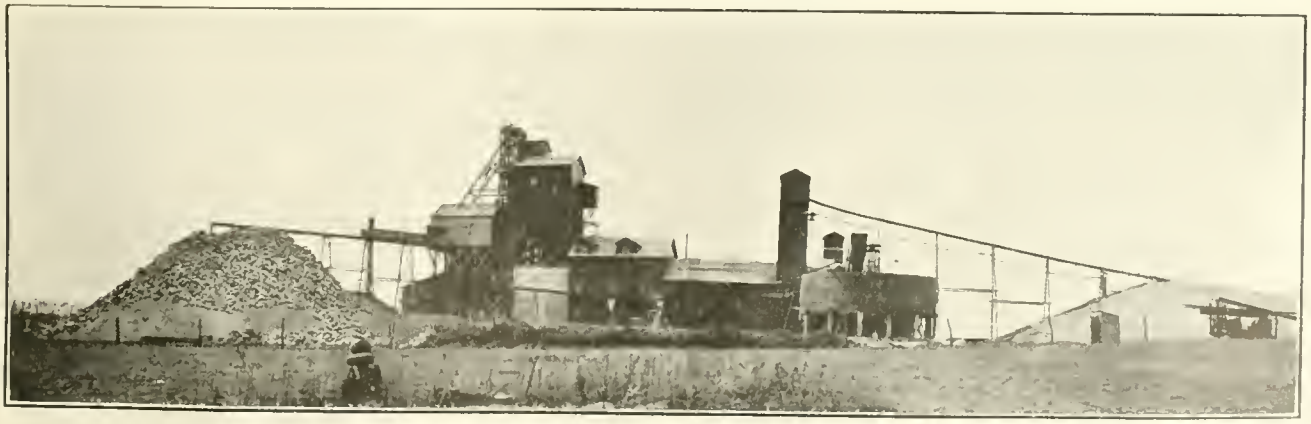
Before I decided upon the method and the machinery to be used, I visited the neighboring mills. The essential points brought out by this investigation were: (1) All the ore, coarse and fine, passed through the crusher and thence through a large set of geared rolls, set so that the face of one shell was in contact with the face of the other; in fact, in the majority of the mills of the district all the rolls are so set, an arrangement that must tend to make an excessive amount of fine; (2) after passing this first set of rolls, the ore was screened in a trommel, the undersize of which went to a jig where coarse and fine material received the same treatment; this required that the jig be so operated as to save the coarse blende, while the fine blende had to take care of itself, so that a part of it was saved, but the remainder was carried into the tailing and was the principle source of loss; (3) although sand jigs were used to treat the re-ground middling from the jigs, no effort was made to concentrate this fine product, which was either lost as tailing or run into a settling-pond from which the water was returned to the mill and the settled sludge periodically washed to waste.

Having these facts in mind, the mill, which was to have a capacity of 500 tons in 24 hours, was designed with the idea of making as small an amount of fine product as possible, as well as to produce the highest grade of concentrate consistent with the maximum zinc recovery. When it was completed, the system was as follows:

The ore was hoisted, in cars by means of self-dumping cages, to an inclined grizzly that fed into a 14 by 18 in.

*'Mining and Milling of Lead and Zinc Ore in the Wisconsin District,' by Clarence A. Wright. Tech. paper 95, Dept. of the Interior, Bureau of Mines, 1915.

'The Wisconsin Zinc District,' by H. C. George, *Eng. & Min. Jour.*, Aug. 21 and 28, Sept. 1, 1915.



EAST SIDE OF THOMPSON MILL.

Blake crusher, placed on the top of the mill bin. This bin is 20 ft. cube, with an inclined bottom and is set 26 ft. above the ground. The bars of the grizzly were spaced 2½ inches apart; when the car was dumped the fine ore passed through into the bin, where it was mixed with that which was crushed. No sorting was done.

From the mill-bin, the ore was fed by an automatic plunger feeder to No. 1 trommel, 3 by 4 ft., having ⅞-in. round openings. The undersize of this trommel went to No. 2 trommel and the oversize to a shaking launder, which conveyed it to a 24-in. Symons disc crusher set with a ½-in. opening. It then passed to No. 1 elevator, which discharged into No. 2 trommel. This trommel was 4 by 9 ft.; the first half of it was covered with a screen of ⅞ in. round openings, while the other half was covered with a screen of $\frac{3}{16}$-in. openings; the undersize of the first screen going to the fine jig; the oversize to the $\frac{3}{16}$-in. screen, the undersize of which fed the coarse jig while the oversize passed to a set of 14 by 24-in. high-speed Chalmers & Williams rolls, set with ¼-in. openings; these rolls discharged into No. 1 elevator.

At the tailing-end of each jig was a settling-box, the overflow of which went to a sump, from which it was pumped by a Butters 6-in. centrifugal pump to a Dorr thickener 10 by 40 ft. The overflow of this thickener supplied the jigs with water; the underflow fed a Deister double-deck simplex slime-table.

The jigs were of the Cooley type having eight cells 36 by 40 in., using punched-plate screens. The plungers of the coarse jig had a stroke of one inch, making 138 r.p.m.; the first cell had a $\frac{3}{16}$-in. screen and the others had ¼-in. screens. Concentrates were taken off the screens of the first six cells, as well as from the hutch of cells No. 2, 3, 4, 5, and 6; the product from the hutch of the first cell going to No. 1 elevator. The product off the screen, as well as the hutch, of cells No. 7 and 8 went to No. 3 elevator, which delivered its material to 18-in. geared rolls, set with shells in contact. The product passing the rolls went to No. 1 elevator.

The plungers of the fine jig had a stroke of ⅝ inch, making 195 r.p.m.; the first and second cells had a ¼-in. screen, while No. 3, 4, 5, 6, and 7 had $\frac{3}{16}$-in. screens and No. 8 a ¼-in. screen; nothing was taken off the screen of the first two cells, but concentrates were taken off the screen of cells No. 3, 4, 5, and 6; from the hutch of the first cell a lead concentrate was drawn, while the product from the hutch of No. 2 cell went to No. 1 elevator; the hutch of cells No. 3, 4, 5, and 6 produced concentrates; the product off the screen as well as the hutch of cells No. 7 and 8 went to No. 3 elevator.

The Disc crusher and the trommels received water from a 3-in. American Well Works centrifugal pump, taking water from the discharge of the mine-pumps.

The crushing and screening section of the mill was driven independently of the concentrating section, each section being driven by a 50-hp. motor, the object being to prevent losses caused from stopping the mill, for at such times the jigs become overloaded with material and at the time of starting up there would be a rush of water and more material to the jigs, whereby a large part of the ore on the jig is washed away before it can be concentrated. By starting the concentrating section first and supplying water for concentration while the crushing section remains idle, a large part of this loss is eliminated.

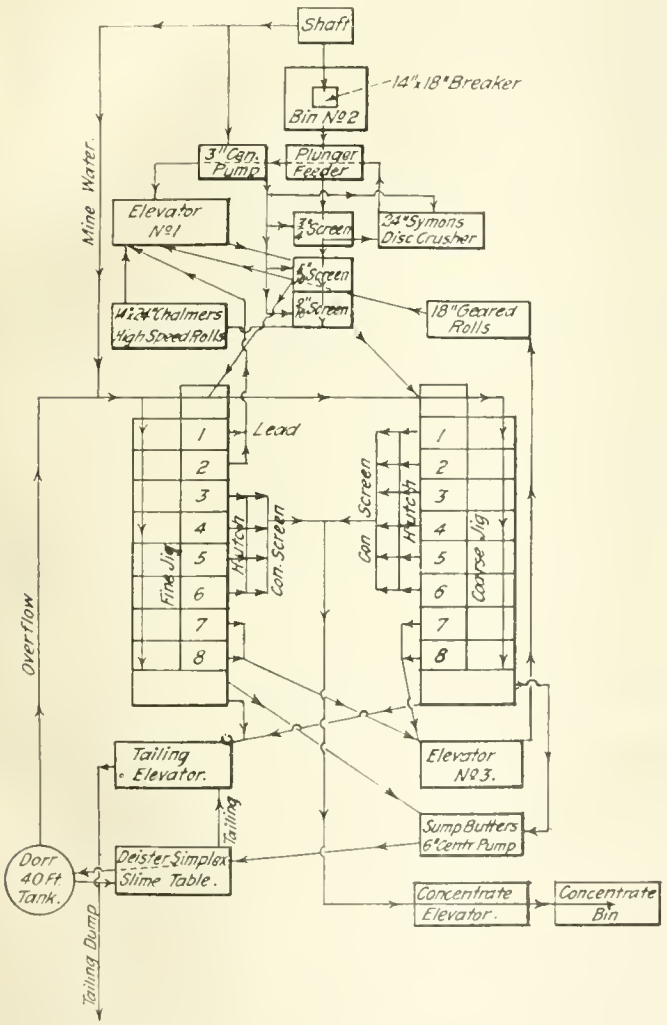
After the mill had been in operation a month, it was demonstrated that the feed to the coarse jig carried a certain amount of fine material that passed through the jig-screens, causing the concentrate of the entire mill to carry a high proportion of lime, as 40% zinc and 4% lime; also that so much water went to the fine jig that the top-water was excessive and thus did not allow the fine material to settle in the jig-cells, but washed it into the tailing. The Dorr thickener proved most beneficial, being able to handle *all* the waste water of the mill (except that lost in the tailing), recovering it as a clear overflow, while its underflow made a satisfactory table-feed and obviated the necessity for a sludge-pond with its periodic cleaning, but the arrangement of connecting its overflow direct to the jigs made a poor water-supply system, especially as in the mine there was a shortage of water, which prevented regulating a steady flow to the mill; in fact, the entire arrangement was such that if either the mine-pumps or the Butters pump stopped there was no water for the mill, thus causing choked and overloaded machines that had to be put in a normal condition before the mill could again be started.

In order to make a cleaner concentrate on the coarse jig and reduce the losses of the fine jig, No. 2 elevator was built and the flow was changed from the original system as follows: the undersize of the first half of No. 2 trommel is sent to No. 2 elevator, which discharges into a settling-box at the head of the fine jig; the settling-box discharges through the spigots onto the jig, while its overflow goes to the sump of the Butters pump; the hutch of the second cell of the fine jig is sent to No. 2 elevator as well as the hutch of cells No. 1 to 6 of the coarse jig and the product of the 18-in. rolls. The concentrates improved to 47–50% zinc, and 1.5% lime.

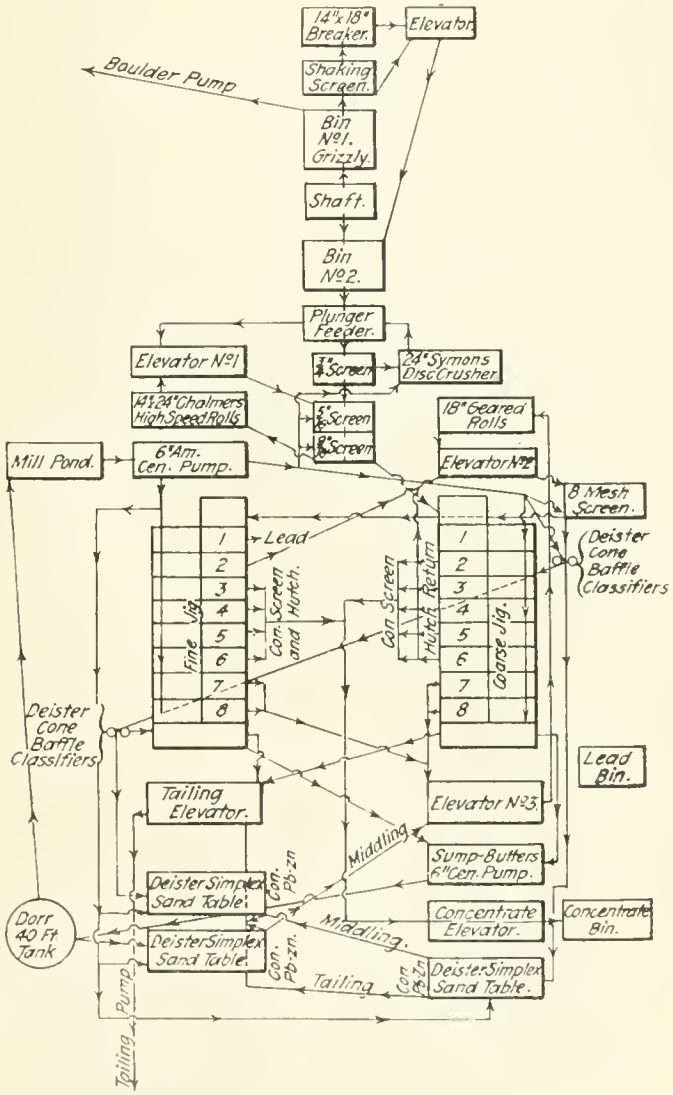
The water system was also changed; the 3-in. centrifugal pump was discarded; at the side of the mill a pond 50 by 100 ft. was built, into which the mine-water is pumped and the overflow of the Dorr thickener discharges. The water from the pond is then pumped by a 6-in. American Well Works centrifugal pump to the different machines.

After these changes, tests were made on the work of the mill, and the following facts were brought out: (1) the mill-feed assayed 6.9% zinc, while the tailing assayed 1.2% zinc, an 82.50% recovery; (2) the tailing from the coarse jig represents three-quarters of the mill-tailing and assayed 0.6% zinc; (3) the tailing from the fine jig represents one-quarter of the mill-tailing and assayed 3.1% zinc; (4) of the fine-jig tailing 45.81% was coarser than 1 mm. and assayed 0.9% zinc, while 54.19% was less than 1 mm. and assayed 5.6% zinc. It was evident that although the recovery was good there was an opportunity to increase it with an added profit, provided the

blende in this fine product could be recovered as a marketable concentrate; to accomplish this, it would be necessary to remove this fine material from the feed of the fine jig by screening and then treat it upon sand-tables. I had already experimented with a sand-table on the fine material being lost at the mill of the Crawhall mine, belonging to the same company, where the 'rougher and cleaner' system was practised, and, by recovering from the mill-tailing 2½–4 tons per day of concentrate assaying 38–42% zinc with 2.5–3.0% lime, I had demonstrated that a sand-table could be operated



ORIGINAL FLOW-SHEET OF THOMPSON MILL.



PRESENT FLOW-SHEET OF THOMPSON MILL.

successfully; hence there was no question but that tables could recover the fine material being lost on the fine jig of the mill under discussion. I had also proved in both mills that the slime-table recovered so small an amount of concentrate, which was of such a low grade, 16.75% zinc and 6.2% lime, that it did not pay to treat this material on a separate table, but that it could be handled better by mixing with the feed of a sand-table. The low grade is partly due to the fact that the country-rock of the district is impregnated with extremely fine iron pyrite, which during crushing concentrates in the finest product to be treated, so that the finer blende has a much higher percentage of pyrite associated with it than the coarser variety.

In order to use the sand-tables, a trommel 30 by 48 in. with a ⅛-in. round hole screen was placed to receive the discharge from No. 2 elevator; the oversize of the trommel being sent to the fine jig, while the undersize goes to four Deister cone-baffle classifiers; the undersize of the first two classifiers feeding No. 1 Deister double-deck sand-table, the next two classifiers feeding a second sand-table; the overflow of the two classifiers going to the Dorr thickener by way of the Butters pump, the discharge of the thickener feeding a third sand-table. All the tables were so riffled as to make a separation between the lead and zinc. The middling from the tables goes to No. 3 elevator to be returned again to the system.

When the tables were tried with this arrangement, it was discovered that the material passing the ¼-in. screen made too coarse a feed for the first table; it was impossible to make a clean separation between the gangue and the minerals; the ¼-in. screen was therefore changed to an 8-mesh wire-cloth screen with 0.078-in. openings; the

product from this was also too coarse with the result that the concentration was most unsatisfactory. The difficulty was overcome by passing the undersize of the 8 mesh screen to one classifier, the underflow of which joined the oversize of the screen as feed to the fine jig, the overflow passed to a second classifier whose underflow fed the first table. This gave material that the table handled with excellent results; the other two tables operated well from the beginning, the only alteration being in the riffling to improve the separation of the lead from the zinc.

Tests lasting 24 hours were made on the work done by the tables, samples also were taken of the fine-jig tailing and the mill-tailing; the results of these tests are shown in the tables below. During these tests from 4 to 5 tons of concentrates were made in each 24 hours. It will be noted from statement A that the table-feed is practically all less than 20-mesh (1 mm. size); evidently from the difficulty in concentrating material coarser than this size, it is necessary to feed the tables with as little material larger than 1 mm. as possible. Statement B shows the lime in the concentrate to be as low as generally obtained in a jig-concentrate; the lead is a little too high on table No. 1, but it should be possible with careful attention to reduce it to that made by table No. 2; table No. 3 makes a concentrate lower in zinc than the others, because it receives in its feed all the slime of the mill through the Dorr thickener, and this material not only increases the iron in the concentrate, but also causes a tailing of high zinc-content. Statement C compares the sizes from the fine jig before and after the tables were used. Statement D compares the percentage of zinc in the tailing of the fine-jig and mill tailing before and after the tables were used. The results need no comment.

In the articles to which reference has been made, it will be noted that it is stated that the operators have not been able to obtain a clean concentrate from tables, for which reason they are not used in the district, the practice being simply to save as much of the fine material as possible on the jigs. The work done by the sand-table at the Crawhall mill, together with the results from the Thompson mill, as given above, disprove this contention. What has been done at these mills only illustrates what can be done at other mills in the district, as is further proved by the fact that the tailing formerly produced and in some cases that now being produced is being re-treated with jigs at a good profit. The further argument, often heard locally, that table-concentrates are too low in zinc and too high in lime to pay for operating tables, is also a fallacy. The lime can be held within the necessary limits by setting the tables to throw part of the blende into the middling product for re-treatment on the table; as to the percentages of zinc, table-concentrates are a few points lower than that of jig-concentrates and in most cases would have to be roasted; however, it is to be noted that few of the mills produce a concentrate sufficiently high in zinc to be sold direct to the smelter without roasting—it must be roasted; if the concentrates

from the jigs must be roasted, there is no valid reason why as much concentrate as possible (in some cases 2 to 4 tons per day), should not be saved from the fine material now lost in the tailing, and roasted, thereby yielding a profit. It may be argued that too much of this fine concentrate would be lost in roasting; this has not been found true in our case, for we have roasted many tons with a recovery of 85–87% on the fine concentrate as against 90–92% on the regular mill-concentrates, the former assaying 55% zinc, 2.8% iron, 3.85% lime, and 2.5% lead, as against 58% zinc, 2.1% iron, 3% lime, and 0.8% lead in the latter. However, if the jigs produce a concentrate sufficiently high in zinc to be shipped direct to the smelter, the tables will also produce a correspondingly high concentrate.

It has also been argued by the operators that it is not possible to size the ore before concentration, and produce as good a concentrate as by the systems now in general use; that, if it were possible, the cost of building a mill along these lines would entail too high a first cost. The work at the Thompson mill has conclusively shown that a higher recovery can be made and a concentrate with a lower percentage of lime, and a proportion of lead as

low as that made by the other systems, can be produced by the method of sizing. Further, the first cost of the mill should be no higher than that of the mill built on the lines of established local practice; no more machinery is required than in mills using the 'rougher' and 'cleaner,' or 'one jig' systems; in fact, smaller jigs can be used when sizing, to do the same work as that done by the larger and therefore more expensive ones at present in use; nor does the first cost greatly affect a decision when it is understood that the local practice is to move the equipment of one mine to a new one when the former is no longer productive.

Several tests were made to determine the amount of fine material produced by the system of screening in connection with the use of the Symons disc crusher and rolls spaced between the shells. It was first determined that of the ore hoisted from the mine and delivered to the primary crusher (Statement E), 4.38% would pass a 1-mm. screen; that after passing through the disc crusher and rolls, the feed to the jigs (Statement F) contained 27.83% of product less than 1-mm. size; that, therefore, the crushing machine produced 23.45% of this product. As in one of the articles* mentioned, all the screen-analyses shown were made upon the jig-tailing, a set of screen-analyses was made on the combined jig-tailings, with the result as shown in Statement F. It will be noted that the product less that 1 mm. (that is, on and through the 40-mesh screen) is 12.03 points higher in the jig-feed than in the tailing; this was to be expected in view of the greater friability of the zinc-blende than that of gangue. It will also be noted in comparing this statement with those in the above mentioned article, that this size of product in the jig-feed is in two cases greater than, in one case equal to, and in three cases less than the same product shown in those tabulations; while in the jig-tailing (Statement F), which is the same material as that of the tabulations under discussion, it is 6.8 points lower than the best result given in those tabulations. It would therefore seem that the system of screening and crushing practised in this mill reduced the amount of fine material to a marked degree.

The method of dumping the mine-cars direct to the primary crusher, which was set on top of the ore-bin, developed some bad features: (1) when the crusher was operating, it was impossible to keep the bin from vibrating, the vibration being transmitted to the concrete pillars even when the bin was cross-braced, as shown in the accompanying photograph; (2) if the crusher was out of commission, for any cause, hoisting ceased, or if hoisting stopped, the crusher was idle; (3) it required five men to feed the crusher and break the large rocks that were too large to enter it; (4) it was impossible to sort out barren rock (although tests showed that from 15–20% of the ore hoisted consisted of large rocks containing no zinc), which could have been removed on a sorting-grizzly, thus relieving the crusher of part of its work, while increasing the capacity of the mill.

When it was decided to increase the amount of ore handled to 800 tons in 24 hours it was agreed to change

the primary section along the lines contemplated when the mill was being designed, although the original idea of a belt-conveyor had to be withdrawn in favor of a stone-crushing plant elevator. The change consisted in building a storage-bin, covered with grizzly-bars, set 5 inches apart, for the cars to dump upon; here the barren rock is sorted out, loaded into the cars and dumped on the waste-rock pile; the large pieces containing blende being broken on a part of the grizzly separated from the dumping and sorting parts. The rock from the bin is fed by a shaking screen having 2-in. round openings, to a 14 by 18-in. Blake crusher; the undersize of the screen and the ore passing through the crusher unite in a catch-box that feeds the stone-elevator and is then conveyed to the mill-bin. By this arrangement, the hoisting can be done independently of the crusher, which can be in operation continuously, if necessary; the mill also has a large storage-capacity in case of delays in hoisting; the crusher can operate continuously and independently of the mine, thus having more working-hours; it can handle more ore and break it to a smaller size better suited for the disc crusher, and thus doing more and better work. In other words, it makes a flexible system, while increasing the capacity of the mill without additional machinery in the concentrating plant proper.

The hoisting equipment at the mine consists of a double-drum electric hoist, made by the Ottumwa Iron Works; both drums are rigid upon the same shaft. This is objectionable, for in case of an accident one cage may have to remain idle, or if trouble arises with one of the drums, there is no means of operating the other drum. Cars of a capacity of one ton are used in the mine and are hoisted in self-dumping cages. At the Crawhall mine, cars of 1½ tons capacity, built to dump as a skip, are used, hoisting being done through an inclined shaft. The experience with the large cars, in both mines, is that they have no advantages over the bucket generally used

in the district but possess some disadvantages; being large and heavy, it requires two men to a car; as the men do not like this arrangement, there arises the question of labor difficulties, they permit the men to load rock too large to be handled satisfactorily on the sorting-grizzly; the cars, when loaded with large rock, are in reality but partly filled, they are not as easily handled in the mine as buckets nor is it possible to hoist a larger tonnage with them than with the buckets.

The self-dumping cages work well but have the drawback that during winter weather the locking-dogs become frozen, rendering dumping difficult and operation unsafe; it was necessary to board the entire head frame to overcome this trouble; even then, it was only partly successful. The skip-cars do not give this trouble, but the inclined shaft is an unnecessary expense with no advantages over the vertical shaft to recommend it, as applied to the type of ore deposit obtaining in this district.

In conclusion, the new features in the mine equipment are the large cars and self-dumping cages, neither of which have any distinct advantage over buckets, but, on the contrary, are not quite so satisfactory.

The new features embodied in the mill are as follows: a separate motor for the crushing and concentrating sections; the use of a plunger-feeder, which gives the mill a steady feed—an indisputable benefit; sizing, the advantages of which have been discussed, separating the fine material of ¾ in. size, and less, as soon as it enters the mill, from the product delivered to the Symons disc crusher, which together with the system of screening reduces the work of, and the wear of, the crushing machines; the use of the disc crusher in place of the rolls, which follow the primary crusher in the general mill-practice of the district; and the use of high speed spaced rolls in place of geared (closed and spaced) rolls for regrinding the oversize product of the screens, which machines in connection with the screening arrangement have markedly reduced the proportion of fine material usually produced; the application of the Dorr thickener instead of a sludge-pond, thus saving a large amount of water while furnishing a good feed to concentrating tables; the introduction of concentration for treating the fine material not saved by the jigs, whereby a marketable product is produced, thus increasing the recovery of zinc and therefore an increased monetary return.

It has been the desire of this paper to present the results of an ore-dressing system new to the district, bringing out some of the difficulties encountered and overcome; its development, advantages, and disadvantages, as compared with other methods in use, trusting that it may be of benefit to others who are working for a higher concentration and a better recovery of the zinc-blende from ores of this type.

Quantitative Analysis for Tungsten*

Aqua Regia Method. This method is old, but is used by many chemists who claim it will give good results. The finely powdered mineral is digested with a mixture of four parts of concentrated hydrochloric acid and one part of nitric acid, until it is completely decomposed; the solution is then evaporated to dryness, which operation should be finished on the water-bath, the chloride of manganese and sesqui-chloride of iron dissolved out, the tungstic acid filtered off, washed with alcohol, dissolved in dilute ammonia, separated by filtration from the columbic acid, the solution evaporated, the residual ammonia-salt ignited with access of air, and the tungstic acid weighed.

Fritcherle's Method. This is the standard method for the determination of tungsten in ores, and is given in many publications, sometimes with slight modifications. It is as follows: Weigh into a platinum dish, or crucible, of about 25 cc. capacity, 0.5 gram of the finely powdered ore, add equal quantities of hydrochloric acid and hydrofluoric acid, and digest at slow boiling temperature for about one hour, or until the ore is all in solution, adding from time to time more of each acid. Evaporate down to about half the original volume, to displace the silicon fluoride and excess of hydrofluoric acid. The dish should be covered to prevent loss by splattering. The two acids will entirely dissolve most ores, excepting those containing tin oxides, in which case it will be necessary to filter off the insoluble residue.

Transfer the solution to a No. 3 beaker, add 20 cc. hydrochloric acid and 8 cc. nitric acid, cover and boil down to about 10 cc. to expel all fluorine; the tungstic fluoride will be converted into chloride, and in the presence of nitric acid will be precipitated as tungstic acid, H_2WO_4. Dilute with 50 cc. of hot distilled water, and boil slowly for about half an hour, or until the tungsten is all precipitated, when the beaker should be set back, and kept just below the boiling-point until the solution has cleared. Filter through a Gooch crucible, using an asbestos felt, wash well with hot water, dry, ignite at white heat for five minutes, cool and weigh as WO_3.

Zellner's Volumetric Method. Zellner describes a volumetric method for use where great accuracy is not required. Fuse the weighed and powdered ore in a platinum crucible with three parts sodium carbonate and one part potassium nitrate; cool, dissolve the melt in hot water and filter. Acidify slightly with acetic acid, dilute to 200 cc., boil, and while boiling titrate with a standard solution of pure crystallized lead acetate. This consists of 16.3 grams of the salt, in one litre of water slightly acid with acetic acid. When titrating, a white precipitate forms and settles rapidly on stirring. The end point is the absence of the formation of precipitate and cloudiness.

[Prospectors preferring a rapid method for determining tungsten quantitatively may refer to the instructions by M. L. Hartmann in the issue of April 15.]

*Abstracts from Colorado School of Mines *Magazine*, tungsten and molybdenum number.

The Law of Mines

By Franklin Wheaton Smith

INTRODUCTION. Although the Law of the Apex from the miner's point of view, has not exactly "brought death into the world and all our woe," it has for many years been anathema to the majority of mining engineers and managers. It has cost mining investors a pretty penny in funds raised or dividends withheld to meet the expense of litigation. It has resulted in the suspension of work for years at a time in not a few good mines. It has caused the paralysis of districts.

THE LAW OF THE APEX. The national mining law is still the inadequate patchwork of 1872. Most of the act is commonplace enough. It prescribes what shall be a valid location, how the ground must be marked, held, and how title in fee simple may be acquired. The maximum size of a claim is 1500 by 600 feet. The end-lines must be parallel. They are assumed to be approximately at right angles, and the side-lines approximately parallel with the vein. It is the ordinary furniture of an ordinary house. But in the middle of the first room is placed Pandora's box. Its mischief-breeding content is this: "The locators * * * shall have the exclusive right of possession and enjoyment of all surface included within the lines of their location and of all veins, lodes, and ledges, *throughout their entire depth, the top or apex of which lies inside of such surface lines extending downward vertically, although such veins, lodes, or ledges may so far depart from a perpendicular in their course downward as to extend outside the vertical side-lines of said surface locations.*"

This right to follow the vein down its slope or dip to any depth, into ground owned by others is called 'extra-lateral right.' No miner may follow his vein horizontally beyond vertical planes projected through his end-lines. If veins were simple continuous sheets of ore between definite walls of rock it would be possible to start at their upper edge or outcrop and follow them to any depth. Few are of that type; many of our largest mines are exploiting orebodies that do not resemble even remotely the vein type. Gold-quartz veins approach the ideal form most nearly, but the task of following such a vein from the surface to great depth is often difficult. Orebodies are not continuous, but are lenses within the vein-fissure. Around their edges the vein may be barren quartz or merely crushed wall-rock. In one vein, between two ore-shoots, each a quartz body several hundred feet long and ten feet thick, the vein was represented by a fissure only an inch wide. When there are several veins in a system it is easy to go astray. Intersections often take such form that the apex may belong to either branch. Under the mining laws of Mexico, for example, or Canada, no trouble could follow. Vertical planes through all boundaries limit mining rights in those countries. But under our muddle-headed statute the question of ownership would probably be decided by an expensive lawsuit. Perhaps the winner would take over the entire property of the loser in settlement of claims.

The variety of puzzling litigation-breeding problems that can arise is endless. After 43 years of experience with that statute new phases of the question still appear. Few large mining camps have escaped apex litigation between leading companies. Discord between strong interests in a small community may breed many evils, even may poison the political life of an entire state.

HISTORY OF THE LAW. The act of 1872 is defective in other ways, but the Law of the Apex has generated most of the negative blessings that have been invoked on its framers. The history of its origin tells a tale of the results of depending on the Anglo-Saxon genius for muddling through somehow.

The Act applies to no State east of the Mississippi, nor to Minnesota, Missouri, Kansas, and Texas. It was extended to Alaska in 1884.

The mining industry of the Far West was born in California. Gold was discovered in 1848, two weeks before the treaty of Guadalupe Hidalgo transferred to the United States more than half a million square miles of territory, the spoils of the Mexican war. The military governor of California proclaimed the repeal of the Mexican mining laws, but offered no code in their stead. A multitude of gold-seekers swarmed into the new land and took the whole West for their field. At first placer mining absorbed attention. Gold-bearing quartz veins soon were discovered and deeper mining began. In 1859 the rich silver mines of the Comstock lode were discovered in Nevada. Soon miners and prospectors were working over an area comprising one-third of the territory of the United States. Technically they were trespassers on the public domain. Under the laws then existing, only agricultural land could be taken up. Mineral lands were expressly excepted from the operation of the Pre-emption Act of 1841. Congress took no action. This region was remote. Few, if any, members had the knowledge requisite for adequate and wise legislation. The miners were left to 'muddle through' by themselves. They did exceedingly well; they framed laws and regulations adequate for local needs and pushed the development of the West with unexampled speed. When the lawless element seemed in danger of getting the upper hand, when murder became so common that it would be commented on casually in the phrase "Man for breakfast this morning," then the better element drew together, vigilance committees were formed

and the bands of murderers and highwaymen were summarily exterminated.

Each mining district drew up and enforced its written code of regulations. They aimed to secure fair rights and equal opportunity between man and man to explore, develop, and produce. There was variation in detail, but the underlying principle was the same in the thousand or more districts scattered over the mountains and deserts of the West. That principle, old as mining and basic in the laws of other countries, was that ownership was founded on mineral discovery followed by active development. The regulations permitted the holding of the surface necessary to mining operations. Each locator, except the original discoverer, was limited to one claim on any vein. Its length varied, but rarely was over 300 feet.

Here then were conditions under which surface titles were not to be had; the veins were considered, in effect, as movable property apart from the ground containing them; each locator was limited to one claim of short length along the vein. Under these conditions and dealing chiefly with one class of metalliferous deposits (narrow well-defined veins) the idea of extra-lateral right was adopted. The source of this principle is not known. If it was not a spontaneous development, it may have been suggested by English miners, since in one district in Derbyshire it was the custom in certain lead mines. It was also embodied in the mining law of Sweden, but was abolished in part in 1825 and completely in 1885. It is not probable that any of the pioneers knew that a similar law had been in force in Prussia in the 16th and 17th centuries, but had been repealed because of the interminable litigation it had fostered. British Columbia adopted the principle from our law, but dropped it a few years later because it proved a bountiful mother of lawsuits.

After 18 years of active development under these regulations, reinforced by State legislation giving them legal standing, came the first national mining act, that of 1866. It permitted the purchase of mineral land, granting a patent in fee simple after certain regulations had been complied with and the land paid for at the rate of $5 per acre. In effect it was a summary and average of local regulations supplemented by a land act throwing open the mineral-bearing portion of the public domain. It perpetuated the principle of extra-lateral right. Senators Stewart of Nevada and Conness of California were its chief sponsors. They believed in things as they were, but realized the need for clear titles. At that time litigation on the Comstock lode, with its source in the insecurity of simple possessory titles, was on a scale comparable with the battles fought years afterward at Butte. But be it noted that the latter had their chief source in the Law of the Apex, which became a fearsome thing when applied to the intricate vein systems of that district in Montana.

The supporters of the act of 1866 had to fight proposals to make the sale of mineral lands the source of large revenue. Some advocated selling them to the highest bidder, regardless of possessory titles. One bill set the minimum price at $50 an acre. These plans were inspired by the necessity for reducing the national debt incurred during the Civil War. The friends of the Act rightly took the ground that it would be a national calamity to adopt any system that would close the region to the prospector or discourage his efforts. Senator Stewart said: "Miners as a community devote three-fourths of their aggregate labor to exploration, and consequently are and ever will remain poor, while individuals amass large fortunes and the treasury of the world is replenished and augmented." He advocated the principle of extra-lateral right and defended it in these words: "In some cases a person buying a single acre in a rectangular form would have several mines at the surface and none at 500 or 1000 ft. in depth. With such a division of a mine, one owning at the surface and another at a greater depth, neither would be justified in spending money for costly machinery, deep shafts, and long tunnels."

The Act limited the length of a claim to 200 ft., the width being governed by local rules. Each claim, therefore, contained only about one acre. Senator Stewart adhered to the idea of one claim to each locator, and in his mind, seemingly, was the picture of only one type of ore deposit. The huge orebodies of the 'porphyry coppers' were then undreamed of. He summed up the Act by saying: "The plan proposes to allow the miners who have or who may hereafter occupy and improve mines in good faith and according to local rules, to purchase at the rate of $5 per acre and receive a patent therefor in such form as shall grant the mine with its dips, spurs, and angles to any depth, with such a reasonable amount of surface as the miners shall determine by the local rules to be necessary for the working of the same."

There appears the idea of the vein apart from the land. It has been the source of many troubles. Speaking of the Sitting Bull case, nearly twenty years later, Judge Church said: "This case affords another exemplification of the unfortunate results attendant upon the purpose of the Government to dispose of orebodies as things distinct from the soil."

The existing Act "to promote the development of the mining resources of the United States" was passed in 1872. It fixed the present size of claim (600 by 1500 ft.) and set no limit on the number of claims one man might locate, but retained the principle of extra-lateral right. It was time to stop the 'muddling' method of progress, and draft a statesmanlike act that would protect existing interests and encourage development without putting a premium on litigation. The industry was old enough; there were enough able and farsighted men to be called into consultation to have made it possible to draft an adequate act. The opportunity was allowed to pass. In over 40 years there have been no substantial modifications and the Law of the Apex has become the patron devil of the mining industry. It is reviled as such and has deflected attention from other features of the Act that need revision.

Laws of Other Lands. Before discussing those features, it may be well to introduce some standard of comparison and touch briefly on salient features of the mining laws of other countries.

The Rand, the greatest gold-producing region in the world, has a series of gold-bearing beds of conglomerate that outcrops for 40 miles and dips steadily away from the surface at a moderate angle. Unit claims are small, only 1.4 acres, but there is no limit to the number that may be held. Vertical planes, projected from boundaries, limit mining rights. Strong companies acquired large holdings from original locators. First came the 'outcrop' mines; back of them the first and second series of 'deep-level' properties opened by vertical shafts. Dikes often accompanied by veins too poor to pay, cut the gold-bearing series. They dip more steeply than the 'reefs,' as the lodes are called, and would offer fine openings for litigation under an apex law. But there is no such law and it has been said: "The excellent character of the mining law of the Transvaal is worthy of more than passing notice. So clear and well-defined is it, that while every square foot of ground is taken up for a length of nearly 40 miles by a width of one to three miles, lawsuits between adjoining companies are practically unknown; and as a result the mining-law expert does not exist on the Rand."

Unless it has been passed within a year, Canada has no Federal mining law although there are acts dealing with phases of the industry. About four years ago an act provided that such a law be drafted and the aid of the Canadian Mining Institute was enlisted. Part of the country will not come under the law; some provinces own the public lands within their borders. In others, British Columbia for example, while the Provincial act will govern the greater part of the area, a Federal act will apply in certain parts. The British Columbia act is that most cited for comparison with our law. Prior to 1892 extra-lateral right was permitted. In that year a non-retroactive law was passed making mining claims 1500 ft. square, and limiting them in depth to the ground within vertical planes passed through their boundaries. The new law has worked well in that respect. As in Mexico, the surface does not pass with the mineral rights. Enough land is allowed for operating needs, the remainder is retained by the Crown.

Of the Mexican law it has been said by a leading authority that it "furnishes the best example of a liberal and progressive system of mining laws of any which has heretofore been adopted in any country." The ownership of all metalliferous deposits on public or private lands is vested in the Nation. Title in fee simple is not granted. The Government gives a perpetual lease for a fixed tax per unit-claim. Failure to pay the tax forfeits the ground. Property rights are secure and mines are transferred as readily as if titles were in fee simple.

The unit claim or *pertenencia* contains 2.47 acres and is a square 100 metres (328 ft.) on a side. There is no limit to the number permitted to one locator. Boundaries bear no prescribed relation to the course of the deposit. No 'discovery' or proof of mineral character is required. No act on the ground can give title to the locator; his location (denouncement) is made by applying at the proper mining agency for a Government title. Prior to securing title he is prohibited from making any openings more than 33 ft. long or deep and from shipping ore. Mining rights are limited by vertical planes through the boundaries. Surface rights must be acquired by procedure separate from that for obtaining mineral rights. The locator must put up money for his application and pay his annual taxes in cash, as there is no work-equivalent for the latter. This feature bears hard on the penniless prospector. In short, authority is granted to work a prism of ground of definite horizontal dimensions and indefinite vertical depth; instead of a certain length on a vein or lode the underground behavior of which cannot be predicted.

Congress did not impose the Law of the Apex on the Philippines. Claims are square, 300 metres (986 ft.) on a side and vertical planes through their boundaries limit mining rights. Claims are held as in the United States by annual assessment work to the amount of $100 per claim. A defective feature is that there is no provision for discovery work. By re-locating it is possible to hold ground indefinitely without work. It is necessary, as in the United States, that $500 worth of development be done before a patent can be obtained. The Philippine government has the right to provide rules for the regulation of mining. The law works a hardship in limiting each locator to one claim on each lode, though this has been decided by the Attorney-General not to prohibit the holding of any number of patented claims by one person or corporation.

[Vertical side-lines apply in Australia and New Zealand. Litigation is almost unknown.—Editor.]

The Act of 1872. Aside from the apex feature, the act of 1872 has faults that have in one way or another an unfavorable effect on the industry. The Land Office has full records of patented claims but none at all of claims being held by location and assessment. This places upon the applicant for patent the burden of advertising for someone who may dispute his title.

This bit of dialogue does not exaggerate Uncle Sam's general attitude toward the mineral claimant:

Uncle Sam: Well, son, what is it?

Son: I want a patent on the Twilight claim in the Moonrise mining district, Apache county, Arizona.

Uncle Sam: I guess you can have it if you are sure that none of the other boys has beaten you in locating the ground.

Son: Oh, I am sure of that.

Uncle Sam: I'm not though. I can tell in a minute after your surveys are in if you are trying to take ground I have already sold, but unpatented locations might be ten deep on that Twilight of yours and I'd be never the wiser.

Son: Aren't you rather careless about your property?

Uncle Sam: Maybe, but I've always had more than

I knew what to do with. Tell you what, though; you go ahead, put up your deposit with the Surveyor General and pay for the rest of the work. Then before you pay me the $5 an acre you can advertise your application at your own expense for 60 days. If anybody else thinks he owns that ground he'll probably find out what you are up to and you can settle it between yourselves. My inspectors will drop in and have a look at the ground to see that you are not trying to put one over on me. If no one raises a howl you can have your patent."

Discovery. The Act provides that "no location of a mining claim shall be made until the discovery of a vein or lode within the limits of the claim located." This provision served its turn in the early quartz-mining days but now, like the Law of the Apex, it is a creed outworn.

Cheap transportation and improved technical methods have fostered big undertakings that handle tremendous tonnages of low-grade ore. Copper mining has become a manufacturing industry with scores of millions of invested capital. Great mines have been developed where the barren surface gave promise only to those who could read the obscure signs. In one district this surface may be limestone, tilted, twisted, fractured, perhaps with a little red stain of iron in pockets or along fracture-planes. In another it may be an area of porphyry, fractured, altered, bleached white or stained red, threaded by minute veinlets of quartz.

These mining operations require much capital, large areas, and secure titles, of course. To make it possible to grant the latter, to make the law cover such cases, the word 'lode' has been given the broadest significance. Justice Field ruled that a lode need be neither ore nor an orebody, but was "whatever the miners could follow and find ore." It was decided "that the definition of a lode must always have special reference to the formation and peculiar characteristics of the particular district in which the vein or lode is found." But even so, there have been disputes and under a former administration, decisions of the Department of the Interior, which cannot be appealed to the courts, left miners wondering where they stood.

This is not an attack, direct or indirect, on the principle of Conservation. The question of the comparative value of the land for other purposes would not be overlooked. If the 'discovery' clause were dropped the change would give the miner greater security, but it would foster neither fraudulent locations nor extravagant exploitation of mineral resources. Mineral land costs more than any other kind of land in the public domain. The $5 per acre paid to the Government is but a fraction of the cost. Including the entire cost of procedure and the $500 worth of development required, a patented claim of full size (20.66 acres) costs the patentee nearly $40 per acre.

The demand for a "discovery of a vein or lode" does not exist in the Mexican law; it has been made practically a dead letter in British Columbia. There is a strong sentiment in favor of its omission from the new Canadian act. Certain decisions of the Department of the Interior between 1910 and 1912 strengthened the sentiment in this country.

Power of the Department of the Interior. The Secretary of the Interior holds one of the most difficult positions in the Government. He guards the natural resources of the Nation. It is not often that the country has been as fortunate in the quality of the man holding the portfolio as it is at the present time. The General Land Office administers the public lands. Disputed points are decided by the Commissioner. Appeal may be taken from his decision to the Secretary of the Interior from whose decision there is no appeal.

For 30 years the Department followed the courts' broad rulings on what constitutes a 'lode' and a 'discovery.' This attitude of the courts and of the Department is illustrated by a departmental ruling made in May, 1911. An applicant had been denied his patents. He appealed to the Secretary who directed that they be issued, for the following reason:

"The defendant company has shown its faith in the property by expending about $100,000 on it. Its good faith and belief in the ground are not impeached. The weight of the evidence shows that some mineral of some kind, however slight, has been found in each claim. The ground has no substantial value except for its mineral uses. The decision appealed from would have the tendency to stifle honest effort in mining explorations and instead of encouraging the development of the mining resources of the country would greatly retard it."

Four months later, under the same Secretary, in the East Tintic case the Department abandoned its long-held attitude and supported its refusal to issue patents with these words,

"It is evident * * * that * * * title to the claims is sought essentially on account of their possible value for certain unexposed deposits supposed to exist at considerable depth beneath the surface, having no connection, so far as shown, with any deposits appearing on the surface. The exposure, however, of substantially worthless deposits on the surface of a claim; the finding of mere surface indications of mineral within its limits; the discovery of valuable mineral deposits outside the claim; or deductions from established geological facts relating to it; one or all of which matters may reasonably give rise to a hope or belief, however strong it may be, that a valuable mineral deposit exists within the claim will neither suffice as a discovery thereon, nor be entitled to be accepted as the equivalent thereof.

"To constitute a valid discovery upon a claim for which patent is sought there must be actually and physically exposed within the limits thereof a vein or lode of mineral-bearing rock in place, possessing in and of itself a present or prospective value for mining purposes; and before patent can properly be issued or entry allowed thereon, that fact must be shown in the manner above stated."

This decision caused widespread alarm in the mining regions. For 30 years there had been a quiet confidence that claims located and developed in compliance with

existing rulings and court decisions would be patented when their owners were ready. This decision was applied in other cases. In effect, it was retroactive legislation by an individual official who had but a short tenure of office. It upset the precedent of years and arbitrarily depreciated the value of the property of many men. Yet there was no appeal to the courts. The policy of Secretary Lane has been broad and liberal, yet vigilant. It has been formulated by an able man who knows the West and its needs. But another administration may see in power a man whose arbitrary acts will again cause trouble and injustice.

Any proposal to limit the power of the Secretary of the Interior should receive the sharpest scrutiny. But is it not reasonable to ask that in a case like the one just cited an appeal to the courts be permitted?

Conclusions. Only a few main points have been touched upon. Other large subjects have not been mentioned; namely, placer claims, coal lands, and leasehold *v.* ownership in fee. The discussion has been limited to the act under which mineral lands are acquired and held. Mining regulations, touching the safety of workers, hours of labor, and operating conditions in general are not a part of this subject. The changes most needed are:

First, since it is hardly a controversial subject, may be put the need for adequate records of claims that are held by location and annual assessment. Let locators, as condition to clear possessory title be compelled to record their location notices within 90 days, giving full and clear description of their claims. Each county recorder should be required to transmit certified copies to the local Land Office. Most of the public domain has been surveyed. Were this work completed and this recommendation enacted, the maps and records would show what land has been patented, what is held by location, and what is still the property of the Nation.

Secondly, the conditions discussed under 'Discovery,' and the specific point raised in the discussion of the 'Powers of the Department of the Interior' may be corrected by eliminating the demand for a "discovery of a vein or lode." This proposal is believed to have the support of all who are familiar with geological and operating conditions. It has been specifically supported by the Director of the U. S. Geological Survey in these words: "The same knowledge of natural conditions that leads to the suggestion of a repeal of the law of the apex forces the further suggestion that discovery of ore in place cannot be made universally a prerequisite to the location of a mining claim."

Coupled with the repeal of the 'discovery' clause might be a provision for making effective by inspection the existing requirement for $100 worth of development annually on each unpatented claim. This would tend to reduce 'blanketing,' the covering of a district with claims located by a few men for speculative purposes. Where orebodies are deep-seated, assessment work on the surface is a perfunctory and useless expenditure. It would be well to permit owners the alternative of paying the equivalent tax to the treasury.

Thirdly, the Law of the Apex. This old culprit still has his adherents, for there are always men who fear to change the *status quo*. A change to vertical bounding planes would affect only locations made after the passage of the new act. No existing claim, patented or unpatented, would suffer curtailment of the right it now enjoys. The accumulated experience of the world confirms the wisdom of the 'vertical prism' rule. In some districts in the United States, Bisbee and Morenci, for example, vertical-plane agreements have been in force between operating companies for years. It will be urged by opponents of change that so much ground is located that it is not worth while; that the courts have made the law plain; that the prospector will be discouraged. It is believed that to all such arguments a convincing answer can be returned. This change in the law might be made to carry with it a change in the size of the claim, making it, say 1500 ft. square, as was done in British Columbia.

None of the proposed changes strikes at the rights of the poor man. He does little actual mining on his own account. His profit (aside from 'leasing' or 'chloriding' operations) comes from the sale of claims, usually unpatented, that he has located and slightly developed by his own labor. If the prospective purchaser be made to fear that he will be unable to confirm his possessory title by a patent, the sale will not be made. The poor man is dealt the harder blow. Elimination of the requirement for a discovery of mineral will be to his advantage, as well as to the advantage of operators on a larger scale. The Law of the Apex delivers its worst blows against the operators of successful producing properties.

The shortcomings of the Act of 1872 have been discussed among mining men for years. It is believed that the recommendations made in this article have the sanction of the leaders of the profession, men who have watched the operation of the Act since its birth.

The annual coal output of the world has been for several years about 1⅓ billion tons, of which the United States has produced approximately 40%, Great Britain 23%, and Germany 20%. These three countries produce 83% of the world's coal. The United States exported but little over 20,000,000 tons in 1912, most of which went to Canada; Germany exported over 34,000,000, the largest customers being Austria, Holland, and Belgium; Great Britain exported 72,000,000 tons, France, Italy, and Germany being the largest customers. Efforts are being made to increase the coal trade of the United States in Latin America and Europe.

Gold received by the San Francisco Mint during March was 442,027.12 oz. fine, valued at $9,137,511.53. Australian bars and English coin amounted to 280,178.295 oz. of this. Silver received was 111,635.21 oz., worth $82,156.07. Gold coinage totaled $3,920,000 in double eagles, and copper $2000. For the Philippines was coined ₱169,000 in 20-*centavo* pieces. Coin, bullion, etc., on hand at the end of the month amounted to $374,759,344.63.

Oils for Flotation

By Chas. Y. Clayton and C. E. Peterson

INTRODUCTION. Flotation is today attracting the attention of the metallurgist, chemist, physicist, and intelligent technical man in general. The application of the process is making great strides, but the success of it is hindered by the lack of knowledge concerning the many variables that affect the operation. A mill may be running smoothly for weeks at a time when, without apparent reason, the froth dies and everything goes wrong. Sometimes a change in the ore does this, sometimes the water supply, sometimes lubricating oils get into the system, and sometimes the tube-mill is to blame. It is up to the flotation man to study these variables more carefully and get a better control of them.

We know that the sulphides, or minerals with a metallic lustre, can be floated either with or without oil and that the carbonates, silicates, etc., cannot be floated so readily. Why do certain oils have the power of selecting certain minerals? Why do certain oils produce a froth? Why do certain oils give a watery froth? Why do some give an ephemeral froth and others a tough one? Of the thousands of oils known, only a few classes have found successful application in this new process. Is it because others will not give results or is it because they have not been tried?

Among the oils used at the present time are the wood-oils, the coal-tars and their derivatives, water-gas tars and derivatives, the fixed oils and fatty acids, petroleum products, and occasionally an essential oil. By a study of these groups and the oils available in each group it will be seen that only a small percentage of the various oils is in use. Why is one oil better than another?

In buying oils for flotation it proves often that the same oil, supposedly, gives different results. The method of manufacture and the care of an oil before it is used play important parts in successful practice. The properties of an oil may vary by reason of oxidation, exposure to light, or slight differences in the method of manufacture, especially the distillation temperature in the common flotation-oils. In wood-oils the composition may vary with the species of wood from which it is obtained.

The trend of work today seems to be to study flotation from the standpoint of the ore, its electro-static

charge (so called), etc., and from the standpoint of colloidal chemistry. We believe that, in addition, a study of oils would give a better understanding of the process and of the variables concerned, while also aiding in the solution of certain theories not yet advanced.

This leads us to the question, what property or combination of properties make oils valuable as flotation agents? Thinking that a careful study of oils and their properties might lead us to the solution of this problem, we made the experiments herewith recorded.

From the scanty literature of the subject it would seem that the chief factors are:

1. Di-electric strength.
2. Optical properties, the power to absorb certain rays.
3. Insulation value.
4. Viscosity.
5. Saponification value.
6. Water-soluble content.
7. Degree to which an oil (as a whole) is dissolved by water.
8. Facility to be emulsified.
9. Surface tension.
10. Specific gravity.
11. Chemical composition.

In attacking the problem the first step was to classify the available oils into groups. The oils so far tested cover a large field and can be divided as follows: Fixed oils, fatty acids, essential oils, wood-oils (including the resins), coal-tars and derivatives, water-gas tar and derivatives, petroleum and derivatives.

In making this classification we realize that some groups overlap, that is, contain like compounds, but the idea was to get a classification that would show the source and be easily understood. In addition to this general classification, oils were studied in detail and technical articles abstracted, giving a volume of matter too large for publication at this time.

The next step was to classify oils as to their flotation-value. This was accomplished in test-tube and machine tests. By shaking small quantities of oil, water, and ore in a test-tube and noting the action, we obtained a general classification of oils: frothing oils, selective oils, oils that froth and select, and oils that are seemingly inactive. The data were tabulated to aid the machine tests. The machine tests were made in a modified Hoover machine, as shown in the accompanying drawing. The capacity of this machine was 4000 cc. of water and 800 grams of ore, making a ratio 5 : 1. The agitator gave 1700 r.p.m. The time of each test was 20 minutes.

Since making these tests we have found that it is advantageous to replace the small circulation pipe, connecting the agitator-box and the spitz, with an air-lift. Throughout this work the only variable was the *kind* of oil.

Ore Used. In tests numbered *D*1 to *D*109 an ore composed of dolomite and galena was employed. It gave the following screen analysis:

	Through mesh	On mesh	Weight Lb.	%	Cumulative %	Lead %	Total lead %

		500.00	100.00			100.128

The results of the machine-tests are given in tabular form.

CONCLUSIONS. The results are interesting and show the possibility of using a great variety of oils if they were purchasable at a low price. The results also indicate our inability to give to oils flotative values in numerical terms and the impossibility of getting the true values of oils that give no scum or froth, such as the coal-tars and crude petroleums. It is known that these are good selectors. The tabulations show further that oils vastly different in consistence have similar flotative values. They also bring out the fact that a great deal of work must be done before those properties of oils which give them flotative value are understood, for instance, why do oleic acid, cottonseed residue, and others froth and lift dolomite, while citronella, wood-creosote, pine-oil, and others froth and float galena?

The following experiments suggest themselves and are being attempted:

1. To determine whether there is any relation between an oil's selective power and its di-electric constant, or an oil's frothing power and its di-electric constant.

2. The relation, if any, between an oil's selective power and its viscosity or an oil's frothing power and its viscosity.

3. Whether the oil's surface tension or film strength plays any part in an oil's frothing power or in an oil's selective power.

4. Whether the saponification value bears any relation to the flotative value of an oil, either frothing value or selective value.

5. The facility with which oils can be emulsified, and their flotative value.

6. The oil's water soluble content and the value of it to flotation.

7. The degree to which oil is soluble in water, soluble as a whole, and the value of it to flotation.

FLOTATION MACHINE USED IN THE MISSOURI SCHOOL OF MINES.

8. The quantitative effect of the use of frothing oils and of the use of selective oils.

9. The relation between a mineral's di-electric constant and its tendency to be floated. The sulphides have di-electric constants approaching infinity.

10. The grouping of oils as made by the chemist and the flotation-values of these various groups and to ascertain if the members of each group have similar value as selectors or frothers.

11. The effect of various salts and amounts of salts on the flotative value of an oil or combination of oils. Do these salts affect the surface of the mineral, do they combine with the oil, etc?

12. To show by micro-photographs how oils and bubbles attach themselves to minerals.

13. Whether classification is an aid to flotation.

[Much duplication of work in the testing of oils for flotation can be avoided by publicity such as the above. We invite discussion of the subject.—Editor.]

Central America is portrayed as a thriving and prosperous region in a new handbook issued by the Department of Commerce, Washington. Mr. Garrad Harris, the author, finds that the United States furnishes 50% of the imports for these republics. The Guatemalan banana industry, which has been attracting American capital, is cited as an illustration of what should be done on a larger scale to promote economic and social intercourse. Letters for Latin-Americans, the author states, should be put into good Spanish, containing no technical terms or 'Americanisms.' A curious result of an innocent Americanism was the distrust felt in British Honduras for American condensed milk that bore the sinister label 'Made at our Plant.' This was interpreted to mean that the milk was artificially made from a plant. When the label was changed, the milk became popular. The title of the new publication is 'Central America as an Export Field.' It contains 229 pages, includes an outline of a route for commercial travelers, and sells at 30 cents.

The Seneca-Superior silver mine at Cobalt is said to be nearly worked out. The mine has lasted less than four years, but has produced over 5,000,000 oz. of silver at a notably low operating cost. W. E. Segsworth, the consulting engineer who promoted the company, holds out scant hope of discovering another vein. Profit in 1915 was $568,501.

Butte, the greatest copper-mining city in the world, has a population of 45,000. It has an altitude of over a mile. Built on a bald hill around the rich copper and zinc mines that are its sole support, it is a district of high wages and ambient industry.

CONCENTRATES

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

COST of removing mass copper from No. 12 level of the Ahmeek mine in Michigan is 1.5c. per pound, exclusive of smelting.

DREDGING RESULTS on the Pato concession in Colombia during 1915 yielded 2% over the drilling estimates, the operations being in closely drilled ground.

CORROSION in pipes is caused directly by air in the water. De-aeration of the water at moderate expense, it is believed, will increase the life of some piping systems four or five times.

SCREENS in the tube-mill circuits at the Nipissing mill, Cobalt, collected 176,158 oz. of silver metallics in 1915, but the practice has been discontinued as the extraction was not improved or cost lowered.

CELLULOID has been found disappointing as a material for making mine models; it not only warps, but expands and contracts with changes of temperature and humidity so that it is unsatisfactory for this purpose.

ACCIDENTS to the hands and arms of workmen constitute 31% of the non-fatal injuries in metal mines, while injuries to the feet and legs are 36% of the total. The head receives only 7.31% and the face only 4.19% of such injuries.

CONCENTRATE TREATMENT at the Goldfield Consolidated in 1915 cost $4.109 per ton, equal to 24.2c. per ton of ore milled. This included raw cyanidation, filtering, roasting, acid treatment, cyanidation of roasted material, precipitation of gold and copper, etc.

CENTRIFUGAL PUMPS have given satisfactory results at several Rand mines. At the Crown Mines, centrifugal units lift 1000 to 1200 gal. per minute a height of 2200 to 2500 ft. In that region centrifugal pumps are preferred for handling heavy flows of water.

'STAINLESS' STEEL for use in instruments or cutlery where rusting or tarnishing are especially deleterious is now manufactured in England. Sir Robert Hadfield at a meeting of the Faraday Society indicated that a typical analysis of the steel is: chromium 12.7%, iron 86.6, carbon 0.28, silicon 0.01, manganese 0.12, cobalt 0.45%. Experiments are being conducted to determine this steel's resistance to acids, sea-water, etc.

ALUMINUM DUST, ingots, and plates, used for precipitation of silver, averaged 42.1, 21.04, and 23.64c. per pound, respectively, at the Nipissing mill, Cobalt, in 1915. These high prices make a substitute necessary. Experiments on a large scale with sodium sulphide as a precipitant, the resulting silver sulphide being de-sulphurized by aluminum ingots in a caustic soda solution before being reduced to bullion, have been satisfactory, and this procedure will probably be adopted.

AIR-LIFTS have given good service in unwatering mines, and in raising oil from wells, as in southern California. Essentially an air-lift is a pipe, say of 4-in. diameter, extending for 30% or more of its height into the water or oil to be pumped; discharging into this pipe near its bottom is a small compressed air pipe, perhaps of 1¼-in. diameter. The discharge comes up to the larger pipe in spurts of alternate water and air. The only equipment necessary is an air-compressor and pipe. In narrow shafts where there is not room to hang a sinker-pump, an air-lift is particularly convenient because all the space required is for the pipe.

VANADIUM ORES do not occur in any particular kind of rock. In Colorado they are found in two forms, in the vanadium mica, roscoelite, which, in minute flakes, impregnates a fine-grained sandstone, to which it gives a sage-green color; also in carnotite, a canary-yellow hydrous-potassium uranium-vanadate, which is also found in sandstone. At Minas Ragras, Peru, where the largest known deposits occur, the vanadium is in the form of a sulphide in an asphaltite vein. Vanadium occurs in large quantities in arid and semi-arid regions, although the vanadium-bearing sandstone has only been found in the United States in Colorado and Utah. Outside of Minas Ragras no vanadium in commercial quantities is found in asphaltites. It is not safe to say that vanadium will be found in any particular kind of rock, although in any one region it would be well to prospect for vanadium under similar conditions known to exist commercially in other regions. The largest use of vanadium is as an alloy in steel; it is quoted at $1.25 per pound.

PUMP-VALVE facings for the large 18-in. valves of Nordberg triple-expansion fly-wheel pumps in the Old Dominion mine, Globe, Arizona, gave trouble by reason of sand in the water. Brass, steel, fibre, and leather valves were tried. With clear water, the brass valves, costing $15.37 each, averaged 37 days of service; steel valves, costing $3.09 each, lasted 70 days; fibre valves, costing $17.82 each, lasted 105 days; and leather valves, costing $3.86 each, lasted 64 days. The fibre and leather valves are discarded when worn out, while the brass and steel valves can be re-faced for 55 and 65c., respectively. Finally it was decided that steel-faced valves are best for normal conditions of clear water, while fibre and hard leather valves are best for sandy water, lasting 4 to 6 days. With the Prescott triple-expansion pumps, using smaller valves, hard rubber gave best service. Generally speaking, more and smaller valves are preferred to a few big valves for sandy water; but the reverse seemed true with the large fly-wheel pumps when running at high speed, by reason of breakages of the small valves. These notes are from a paper by P. G. Beckett to be read at the Arizona meeting of the American Institute of Mining Engineers.

Mining in Colorado

By George J. Bancroft

IN attempting to outline recent mining developments in this State, I feel in a position similar to that of the barnyard hen that hatched out a mixed setting of eggs, consisting of ducks, guinea-hens, pheasants, turkeys, and chickens. After a few weeks' growth, it was extremely difficult for the old hen to keep her mixed brood all in sight at any one time. So it is with me. I am as limited in intellect in proportion to the present development of the mining industry in Colorado as the old hen was limited in instinct with respect to her varied family. Mining in Colorado is expanding along the lines that my professor in college taught me was characteristic of an explosive, namely, that it expanded "with equal force in all directions."

Among the metals that are being mined in this State at the present time are gold, silver, lead, zinc, copper, tungsten, iron, manganese, radium, vanadium, molybdenum, uranium, and cadmium, to say nothing of oil, coal, lime, marble, and a dozen other non-metallic minerals.

Inasmuch as I am in no position to describe properly the advances that have recently been made and now are being made, in mining development, I have decided to devote the space, which our editor so generously allows me, to telling something about the activities of a few of our fellow-workers in the mining field, whose operations I happen to know about. Among the gold miners, A. E. Carlton has "come back." For several years it seemed that the trained intellect and fighting force of this splendidly energetic American had been lost to the mining world. Beginning with his wonderful accomplishments in the Vindicator-Golden Cycle deal last year, we again feel the influence of this strong personality. It reminds me of the 'helper' engines that used to couple onto the rear of the Pullmans going over Soldier Summit. You felt the throbbing powerful push from the moment of coupling. A half-dozen rejuvenated Cripple Creek mines, a $5,000,000 beet-sugar company, and an automobile highway to the top of Pike's Peak are among his more recent accomplishments.

George E. Collins is entitled to great credit for the efficient and economical management of the Mary Murphy* mine near Buena Vista, on the Arkansas river. This mine was always considered a hard proposition on account of the complex character of its ore. Mr. Collins reports a net earning of $220,415.45 for the fiscal year recently passed. Careful and intelligent milling, coupled with economy and efficiency in all lines, led to the above most gratifying results.

Irving T. Snyder and H. P. Nagel are the two young men who have brought the Vindicator mine to its present state of efficiency and profitability. This mine, at Cripple Creek, has established a new record for rich gold ore at maximum depth. The manager, Irving T. Snyder, reports the cutting and development of the Ready Money vein on the 2025-ft. level. This is 200 ft. lower than any previous workings on this vein. The volume and grade of the ore are reported as being "very satisfactory." The Ready Money vein is only one of many veins exploited by the Vindicator company. The Golden Cycle shaft of the same company is now down 2225 feet and the work of cross-cutting to the orebodies will soon begin to show results.

Clarence C. Hamlin, president of the company operating the Granite mine, also at Cripple Creek, and James Sylvester Murphy, consulting engineer to this company, are to be congratulated on their success in the consolidation and economical management of the property, which is the consolidation of the Granite, Dillon, Gold Coin, Monument, and Dead Pine mines. While the Granite has been working out its own salvation for some time, it is in the lime-light at present, because of cutting an unusually valuable ore-shoot in the Little Montana dike on the 1400-ft. level.

Cripple Creek is not alone by any means in reporting rich ore at depth. The old mining town of Central City is doing better than for some time past. Very little outside capital has gone into Central City of recent years and much of the wealth produced there was carried to Europe by foreign lessees, so that this district of Gilpin county was much in need of working capital. The European war has kept the prosperous foreign lessees from returning to Europe and the Central City miners have profited enormously from the tungsten mining in this county and in the adjoining county of Boulder. A little home capital being now available, I think it is a fair guess that more good news will soon be coming from the Little Kingdom of Gilpin, as it is known to 'old-timers.' The strike in the Colorado Carr mine appears to be unusually important. This property is under the management of Arthur Most and it is through his efforts that it is again coming to the front as a gold producer.

In the neighboring county of Clear Creek, there is much activity. For instance, the famous old Colorado Central mine above Georgetown is to be re-opened by the Onondago Mines Company. A deal is under way to complete the Malm-process mill at Georgetown and some strong mining men are taking a keen interest in the matter. S. A. Ionides and John Malm of Denver are back of this movement. The strikes in the Big Five 'tunnel' at Idaho Springs continue to yield handsome returns. George Kimball of Idaho Springs has a hand in this development. The Argo mill has added a flota-

*See report on page 614.

tion plant to its present equipment. Rens Shirmer of Idaho Springs and Richard Parker of Denver designed and built it. The old Alice mine has passed through title-clearing procedure and is ready to go ahead. George and Edward Reynolds are the energizers at the Alice. They have built a mill with their own hands and thereby made the district self-supporting. The Capital, Mendota, Scotia, Seven-Thirty, Pelican, Big-Indian, Ruler, Sunshine, Albro, Santiago, Imperial, and Belden are all in good ore.

In Boulder county, which lies north of Gilpin, there is a regular boom. I was going to say a regular "old-fashioned" boom, but this is not of that kind. In the old days a mining boom was conducted with much stock-selling, much hotel and stock-exchange building, much saloon patronage, and much energy expended in a great many ways other than in mining. The printing-press and whiskey-still were near competitors of the air-drill and rock-crusher in those good old days gone by. This boom of ours in Boulder county is an effective boom, if I may put it that way. At least $4,000,000 of tungsten ore has been sold in the last year and a half. Practically all the wealth created thereby is re-invested in mining in the neighborhood. I never saw a boom with so little hot air. There are dozens of men in Boulder county making $25 to $100 per day with labor of their own hands. The point is that they keep right on using their own hands instead of hiring some one else to do the mining. I came down the hill with eight lessees the other day; they looked much alike, as men are apt to look who are covered with gouge and candle-grease; I induced them to tell me of their earnings. The least fortunate one was making a little less than wages. The most lucky one had averaged $75 per day for two weeks. I asked the latter what his plans were for the future. "Just keep on digging as long as the ore holds out and the price stays up," was his reply, and that remark is characteristic of the district. No excitement, no inflation, no foolishness, just industrious digging, that is all. There has been little mining engineering work in connection with this boom, the reason being that the district was an old gold-mining camp to begin with. There were plenty of mills in the district, and the ground was, for the most part, covered with claims that were patented years ago. Then again Stein & Boerecke of the Primos Chemical Company are intelligent and conservative men. They have been in the tungsten business for 20 years, at least, and they had worked out most of the engineering problems connected with this field during the years when tungsten was only $4 per unit. Furthermore, Colorado miners do not get excited over apex questions as they used to. There have been few important sales. As a result of these several facts and tendencies, there has been but little important engineering work done so far in Boulder county. There is plenty of work to do in the future, however, provided the price of tungsten is sustained. For instance, some one must evolve a method of saving the tungsten slime. Straight oil-flotation won't do it, because the tungsten mineral is an oxide. A modified flotation method has been suggested. Norton H. Brown is one of the engineers who is devoting most of his time to tungsten mining. He not only acts as consulting engineer for several mines, but has two mines of his own. Forbes Rickard, Robert Grant, W. A. Schlessinger, and O. R. Whitaker are among those who have made important examinations for prospective purchasers.

Tungsten prospecting is being energetically pursued all over the State. George H. Barnhart of Ouray is opening the old Dunmore claim in the Red Mountain district. E. Frankenberry of Canon City paid $25,000 for a tungsten prospect near Salida, on the Arkansas river. Nelson Franklin of Cripple Creek is building a tungsten mill at Rollinsville. The Tungsten Metals Corporation of Boulder will build a mill. The Primos Chemical Co. will build central compressor-plants and enlarge its mill. Tungsten is being produced in considerable quantities on Cement creek, in the San Juan. It has been found in the old Silver Bell mine at Ophir. Fred Carroll, the State Commissioner of Mines, and associates have consolidated a group of claims near the Old Bachelor mine at Ouray and will install a flotation mill.

In Summit county, there is more than usual activity. The Wellington, Old Union, Puzzle, Germania, Dunkin, King Solomon, Toledo, St. John, Jumbo, Silver Wave, Country Boy, Jessie, and many others are producing. The old district of Montezuma is commanding a good deal of attention on account of the rising price of silver. The dredges have finished their winter's overhauling and are again pumping gold from gravel to mint. H. J. Reilling is re-investing his Breckenridge gold in a big dredging project in Idaho.

Ezra D. Dickerman of the Star Consolidated at Leadville has taken a contract to produce and ship 70,000 tons of manganese ore to the Colorado Fuel & Iron Co. and allied interests. W. H. Kelso of Grand Junction is shipping high-grade manganese from Thompsons, Utah. E. E. Miller, a mining engineer of Denver, is opening up the old Alicante property near Wortman. Wortman lies between Leadville and Kokomo. He has installed a flotation plant in the old Burma mill. His enterprise is another example of modern processes giving value to orebodies heretofore of doubtful value. F. H. Thompson, manager of the Pioneer mine at Apex, has opened up a nice large body of ore on the Martin vein. W. G. Knape and E. P. Young are building a cyanide mill for the quartzite ores of Red Cliff.

Zinc production is increasing in all the well-known zinc districts. Kokomo reports three new enterprises and increased production from old ones. Leadville has been mentioned so often in these pages that it is hardly necessary again to refer to it. Furthermore, the activities at Leadville are so varied and extensive that it would require a considerable space simply to outline them. At Rico the old Rico Mining Co., the owner of the largest acreage in that famous district, has come to life again and is actively developing. Other properties are increasingly active. The Tip Top and Weston Pass properties south-east of Leadville are active.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

LORDSBURG, NEW MEXICO

RÉSUMÉ OF MINING CONDITIONS IN THE STATE

Mining throughout the State of New Mexico is thriving; many old properties are being opened; lessees at the larger properties are doing well, but some are having trouble in obtaining acceptance of their ore at the smelters, the larger contracts having the preference.

At Tyrone, the Burro Mountain Copper Co. is ready for extraction and treatment of its ore, after several years of preparation. While the initial production will be comparatively small, the company will enlarge its operations at all points during the year and by 1917, should be one of the State's largest producers of copper.

The Carlisle mine at Steeplerock has proved to be valuable. Unwatering was finished, and immense orebodies of both low and high-grade complex ores have been revealed. Timbers on the lower levels were found to be in good condition, and the operators have already begun hoisting lead ore, which is shipped to the El Paso smelter. An experimental mill is being erected, probably of 75-ton capacity, including flotation, electrostatic, and wet concentration. Some of the Carlisle ore has been shipped to the test-plant of the Empire Zinc Co. at Canon City, Colorado. The manager, H. K. Welsh, states that there are 200 men working at the Carlisle. The Carlisle Mines Co. has applied for articles of incorporation through its New York attorney.——Near the Carlisle, the Eclipse Mining Co. is developing and preparing for the extraction of high-grade ores contained in the Eclipse lode.

Several new companies in the State to file articles of incorporation recently have been the Black Hawk Mining Co. of Silver City, the Pecos Mines Co. of Pecos, San Miguel county, and the Ophir Development Co. of Jacarilla, Lincoln county. The Gold Bell Mining Co. of Deming is a recent corporation. Its property is north-east of Hillsboro, Sierra county, and was worked in the early days for the high silver-content.——Near the property of the Gold Bell company, John Sully and associates of Santa Rita are preparing to work the Snake mines. An old type Diesel engine has been overhauled and mining on a small scale has commenced.——The Opportunity mine in the vicinity is also being operated.

At Steins, several transfers of properties have taken place. The Oldem lead and zinc claims have been sold to Tombstone, Arizona, interests; and the Panama mines, sold by John Haydon to T. A. Lister and others of Lordsburg. McKenzie brothers are shipping copper ore to El Paso.

M. M. Crocker has sold his tungsten claims at Gage to the Nevada Hills Mining Co., which has begun work and is to erect an experimental mill soon.

The Chino Copper Co. continues its flotation work, and proposes the early erection of another flotation unit near the tailing dam. Twenty-five carloads of concentrate is being shipped daily to El Paso by the company.

In the Pinos Altos region mining has had a relapse. Several lessees are shipping ore, but the boom, recently quite prominent, has subsided.

At Hanover and Cleveland, the Empire Zinc Co. is adding the final touches to its treatment and power plants.

Zinc mining in Luna county is fairly active. The Mahoney property at Tres Hermanas is being operated; the Azure Mining Co. is also developing zinc claims purchased recently. ——Reports from Mogollon are to the effect that a strike was called by machinists at one of the mines. Operations, however, have not been retarded.

In the Lordsburg district the Eighty-Five Mining Co. is sinking its main shaft for a fifth level; the lowest is at 450 ft. Diamond-drilling is still being done at the Atwood mine of this company.——Near the Bonney mine, Frank Weldon and others have made a rich strike on the Nellie Gray claims, and are shipping the ore to El Paso. There are a number of lessees at work on different parts of the Bonney. The main Bonney shaft is being unwatered.

THE EIGHTY-FIVE MINE, LORDSBURG, NEW MEXICO.

PLATTEVILLE, WISCONSIN

CONDITIONS INFLUENCING ZINC PRODUCTION: POWER, ROADS, ETC.

Severe weather at the beginning and end of March (snow and floods, respectively), shortage of electric power for nearly all zinc producers in the southern districts of this region, bad roads, and at times unsettled markets for zinc-blende, combined to curtail ore production at all points. The railroads were badly damaged also. The city of Galena was under water, and communication could only be maintained by boat. Lumber companies lost much building material, cement, and lime. In the southern districts, especially in the Pecatonica, LeFevre, and Galena River valleys, most of the large mines were filled with water. The northern districts were more fortunate, due principally to the fact that they are situated on higher ground.

Treatment of Wisconsin ore appears on another page of this issue.

The power problem is not improving, but the Inter-State Light & Power Co. of Galena may mend matters by the end of April, as complaints have been investigated by the State Railroad Commission.

For years bad roads have been distressful to outlying producers at the spring break-up; this year was no exception. Organized efforts made a year ago in the New Diggings district to induce the Chicago & Northwestern railway to construct a branch from the Galena line at Hazel Green to this new centre failed. Zinc producers and town authorities constructed a four-mile road, costing $35,000, from New Diggings to Benton. No sooner was traffic started on this road than the

Northwestern immediately had surveyors at work staking out a branch as earlier petitioned, and the construction commenced. The ill-advised policy of the railway company finds echo in acrimonious expressions on the part of operators who threaten to get even. The completion of the new roadbed for vehicles resulted in the starting of auto-truck service for carrying ore and supplies.

Ore shipments in March were 36,816,000 lb. blende, 197,150 lb. lead, and 5,908,160 lb. pyrite.

The gross recovery of crude concentrates from all mines was 32,000,000 lb., and net deliveries to smelters 18,000,000 lb. The Mineral Point Zinc Co. delivered to smelter at DePue 4,870,000 lb. high-grade calcined 'jack.' As usual this company secured about half of the output contributed largely from its own mines. The bulk of low-grade ore was about evenly divided between the National and Wisconsin separators.

Boom conditions prevail at all points in the field. New producers with new equipment are being started in every centre. Much capital is being deflected to Wisconsin zinc mining. So great is the demand for drilling outfits that scores of companies are being formed for prospecting alone on contract agreements.

TORONTO, ONTARIO

Nickel Notes.—Wide Lode in the Dome.—New Cyanide Process at Dome Lake.—Boston Creek Mines.

The nickel question is still very much in the foreground. An Order-in-Council has been issued by the Government prohibiting the export of nickel ore and matte except to British possessions, but as the Premier explained, it does not interfere with the present arrangement by which the International Nickel Co. secures its supplies of raw material from the Sudbury district, as it will continue to export under special license. The prohibition was intended to apply to another company, not named, which, it was discovered on investigation, had been exporting nickel without an arrangement with the Government, and the destination of the shipments could not be traced. Heretofore any exporter will have to satisfy the British and Canadian governments of the ultimate destination of the metal before a license to export will be granted. This action does not by any means satisfy those who are agitating for all refining of nickel to be done in Canada. As the International company has assured the Government that it intends to proceed immediately with the erection of a refinery of sufficient capacity to satisfy all the requirements of the Empire, probably at some point in Nova Scotia, it is not likely that its supplies will be cut off in the meantime. But judging from the growth of the movement, which has been greatly strengthened by war-time tension and the development of Imperialist sentiment, it is altogether probable that as soon as a refining plant is provided, the export of raw material will be put under embargo. The Ontario Nickel Commission is now in Norway and will visit Madagascar and New Caledonia before returning to Canada.

On No. 7 level of the Dome mine the orebody is 244 ft. wide averaging over $5 per ton, with considerably higher gold content in parts. Excavation is progressing for the new steel head-frame, which will be 125 ft. high. March production established a new record, the value being $173,370 from 34,300 tons of $5.05 ore. The Dome has taken an option on the Dome Extension until October 15, 1917, under which, if taken up, the shareholders of the Dome Extension will receive 46,000 shares of Dome Mines stock in exchange for the property. In the meantime the Dome Extension will continue operations on the upper level, and the Dome management will undertake exploration work from its No. 3 shaft.

The statement of the Hollinger company for the month ended February 25 shows gross profits of $169,905 from 30,658 tons of $9.01 ore. Working costs were $3.07 per ton.

Much interest is occasioned by the installation of a cyaniding machine now in progress at the Dome Lake. The process is claimed to yield a high extraction at low cost. It includes a drum 15 ft. long and 7 ft. 6 in. diam., lined with a filter medium of porous brick. Pulp flows into a charge-tank with a dilution of 1:1, and then into the drum where air is blown into it to displace the water. Cyanide solution is run under pressure, and the drum revolved from 1 to 3 hours. The cyanide solution is replaced by a wash solution, and the pulp tailing discharged. Zinc shaving is used for precipitation.

At the R. A. P. syndicate mine, Boston creek, results of recent development have been highly satisfactory. There is high-grade ore in the face of both drifts; east it is 12 in. wide in a 3½-ft. orebody, and west 7 in. wide in a somewhat narrower body. The Miller Independence, at Boston creek, has a fine showing. The vein has been opened in three places, and contains free gold and a telluride supposed to be calaverite. A shaft is being sunk to cut the vein at 40 feet.

CRIPPLE CREEK, COLORADO

General Mining Notes.

A rich surface discovery was recently reported at the Rotten Hole claim, on the south side of Mineral hill, not far from the north boundary of Cripple Creek. The sugar-quartz found on the surface pans gold freely, and the vein-matter in place gives every indication of being persistent.

The Consolidated Mines & Reduction Co., which recently took over the Ella W. property on Tenderfoot hill, has awarded a contract for 300 ft. of tunnel work. This adit will cut the Ella W. vein at an approximate depth of 85 feet.

During the last fiscal year the Granite company made a total gross production of $534,450. After all operating expenses, freight, and treatment charges were paid, the net production was $337,705.

A new cyanide plant is being constructed by W. A. Reed on the former site of the Gaylord mill to treat low-grade ores from the Gold Sovereign dumps. This new equipment will be on the estate of the Dante company, on the south-west slope of Bull hill.

The Vindicator Consolidated has taken over the old La Bella electric-lighting plant at Goldfield, and announces its intention to construct a mill for the treatment of low-grade ores by flotation.

The Isabella mine produced 2385 tons of ore during March; 84 of the 90 narrow-guage cars billed were shipped by lessees, the other 6 were extracted from the company's recently discovered shoots on the 15th level of the Lee shaft. The Isabella mill is again operating at a profit.

DEADWOOD, SOUTH DAKOTA

Custom-Mill Investigation.

Further investigation by the mines and mining committee of the Deadwood Business Club of the feasibility of erecting a custom cyanide-plant at Deadwood is bringing to light additional properties which apparently can soon be depended upon to furnish ore for the plant. At the last meeting of the committee a number of property-owners were present who stated definitely that they could produce ore suitable for treatment in the contemplated mill. For various reasons, one of the most common of which was lack of transportation, they had only produced in a small way in the past. All were agreed that a custom motor-truck would enable them to ship at a profit, as in many cases that service would save them $2 per ton. As a next step in the work it is proposed to engage two of the club members—A. T. Roos and Jesse Simmons—to make detailed investigations of the various embryo shippers with a view to determining the ore reserves in various properties. These men will be expected to sample and report on at least 20 different properties near Deadwood. It is reported that more tungsten deposits have been found.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

JUNEAU

During March the Alaska Gastineau mill treated 162,796 tons of $1.03 ore, compared with 122,856 of $1.02 in February, and 119,914 of $1.42 in January. The recovery last month was 77.47%, with 20.3c. tailing, against 78.56% and 19.8c. in the previous month. No. 2 stope of the east fifth level yielded poor ore. Conditions are improving.

ARIZONA

Bulletin No. 18 of the State Bureau of Mines is on vanadium, by P. E. Joseph. Those interested will find a good deal of useful information. While no production has been reported from Arizona, the ore is found as vanadinite associated with lead in Cochise, Gila, Pima, Yavapai, and Yuma counties. Ore containing 10% vanadic acid is worth 50c. per pound.

GILA COUNTY

To improve the relations between the Inspiration Consolidated and its employees, the general manager, C. E. Mills, has issued a circular to them, in which it is desired that they appoint four to act as a committee to confer with the company on grievances and the like.

During one day last week the Inspiration mine produced 18,000 tons of ore. To do this the hoists did not work the full 24 hours. The coarse-crushing plant only operates two shifts, as the bins are of large capacity. Some more standard-gauge 60-ton railroad ore-cars are soon to arrive.

PINAL COUNTY

(Special Correspondence.)—The Ray Hercules Copper Co. is sinking a three-compartment shaft to 1000 ft. depth in the

MAP SHOWING PART OF RAY MINING DISTRICT

Grace L. claim, situated within the boundaries of the town of Ray. Plans for a 1000-ton concentrating plant are being prepared, and a mill-site surveyed. Up to October of last year drilling on 13 acres, of the 207 in the property, had indicated 3,428,774 tons of 2.36% ore. Subsequent work has widened the mineralized area; holes north and east proving 90 to 145 ft. of over 2% ore.

Ray, March 27.

MOHAVE COUNTY

Lenzite crystals have been shipped again from the Arizona Venture Corporation's property in the Cedar Valley district, in charge of W. D. Grannis. These are used in wireless telegraphy.

ARKANSAS

MADISON COUNTY

Aurora is prosperous and busy under the stimulus of high zinc-ore prices.——The most promising of the new mines is the Red Wasp, 2½ miles north-west of the town. Three drill-holes cut good ore. Mining is done at 110 to 160 ft. depth. In 10 hours the 150-ton mill is producing 10 tons of high-grade concentrate; the ore contains 7 to 12% zinc, and the product 60%. The ore slimes easily, and a sludge department has been added. ——A good deal of drilling has been done on ground near the Red Wasp, with encouraging results.——East of Aurora the United Zinc Co. is getting good returns.——Farther south the Aurora Union company's new 300-ton mill has been started. Ore is mined at 150 ft., but some occurs at 250 feet.

MARION COUNTY

Zinc-ore shipments from north Arkansas in March totaled 3,928,000 lb., mostly high-grade carbonate. The Red Cloud at Rush yielded 480,000 lb., followed by the Philadelphia with 300,000 lb., Leader, Morning Cloud, and Yellow Rose, with 240,000 lb. each, and McIntosh with 180,000 lb. In Newton county the Big Hurricane and Ponca City produced 300,000 lb. each.

CALIFORNIA

AMADOR COUNTY

The preliminary report of the Plymouth Consolidated for March is as follows:

Ore milled, tons	10,750
Gold recovered	$62,300
Working expenditure	32,980
Development charge	5,670
Surplus	$23,650
Other expenses	184

CALAVERAS COUNTY

(Special Correspondence.)—The Pioneer Chief Gold Mining Co. has purchased the Kane ranch. This property borders on the south fork of the Calaveras river, and contains 203 acres of land which partly surrounds the original Pioneer Chief quartz claim. The shaft on this property is now down 390 ft. The solid body of ore was cut at 320 ft., and continues to the present depth, with an average width of 6 ft., assaying $8 per ton. At the 350-ft. level the north-west drift is in 47 ft., 35 ft. of which is in $8 ore, the remainder being in a crushed mass of broken country and ore. The south-east drift on the same level, is in 50 ft. The vein is wider than the drift, which is 7 ft., and is valued at $9.50 per ton. The foot-wall is solid and hard, while the hanging wall is soft and heavy. At 380 ft. in the shaft, the vein gradually runs into the foot-wall, so that workings from now on may be opened in the foot-wall solid

formation and avoid much of the expense of timbering and retimbering. It is expected that the 500-ft. level will be reached by May 10. A small experimental plant for milling the ore mined during development, may be installed during the summer. N. J. Martin of San Francisco is consulting engineer, and J. E. King is superintendent.

San Andreas, April 5.

EL DORADO COUNTY

The Springfield district is increasing in activity. The Noonday copper mine was re-opened last week with 12 men, while 13 are at the Union. Some more work is being done in the Shingle district.

HUMBOLDT COUNTY

Nearly all the snow has disappeared and the Humboldt Copper Co. is to resume work at its Horse Mountain mine. Diamond-drilling is to be started.——The Bonnieville company's copper claims are of promise.——The Gold-Platinum Mining Co. will probably resume at its placer property on New river.——The Corona company is sluicing at Hawkins bar.

KERN COUNTY

(Special Correspondence.)—A 30-ton Lane slow-speed mill and cyanide plant are being erected on the Elephant mine, four miles south-east of Mojave, by Mr. Parnell.——The Mojave Consolidated gold mine was sold at a sheriff's sale March 22 to A. A. Morriss to pay for wages due. This is a good property, but has been burdened with mismanagement. George B. Phillips has been appointed mill superintendent of the Soledad Consolidated Mines Co.'s mill near Mojave.

Mojave, April 9.

NEVADA COUNTY

An antimony vein of good width and high grade has been uncovered on the ranch of R. Johnson, near Grass valley.

PLUMAS COUNTY

The development and equipment of the Walker copper mine, 20 miles east of Portola on the Western Pacific line, is described in the Salt Lake *Mining Review* of March 30 by Will C. Higgins. Utah capital is responsible for the present state of the property. A severe winter curtailed operations, but speed is now in order to get the mine on a producing basis. There are 34 heavily-timbered claims in the group, through which the Bullion vein has been traced for 4800 ft. A shaft has been sunk and adits driven, opening up to 15% ore in good widths. A cross-cut at 125 ft. depth averages 6 to 8% copper and 3 to 4 oz. silver. A cross-cut adit is in 400 ft. to open ore 75 ft. below the shaft-bottom 800 ft. in. Diamond-drilling has recently been done, No. 1 hole being put down 256 ft. from the 65-ft. level. Assays of each 5 ft. for 200 ft. averaged 7.28% copper, $1.11 gold, and 2.7 oz. silver per ton. Further drilling is under way from the 125-ft. level. Reserves are estimated at 50,000 tons of profitable ore. A Leschen aerial tram, 4200 ft. long, is being erected to carry ore to the new mill, 800 ft. lower than the shaft bins. The tram works by gravity, and has a capacity of 250 tons in 16 hours. The plant will treat 100 tons per 24 hours by straight flotation, using the following machines:

Allis-Chalmers jaw-crusher, apron-feeder, Allis-Chalmers ball-mill reducing to 60-mesh, Dorr duplex classifier, Callow cones, four Callow rougher-flotation cells, one Callow cleaner-cell, and Oliver filter. On 6% ore a recovery of 93% is expected, concentrate to contain 20% copper. The estimated cost of producing $68 concentrate (copper at 17c.) is $27.25 per ton. The product will also contain $10 per ton in gold and silver.

SAN BERNARDINO COUNTY

Atolia has now a piped water-supply, making residents much more comfortable. Many improvements are under way at the town. Santa Fe officials visited the place last week. Telephone and telegraph service is now available. About 30 jitney-buses are running between Atolia and Johannesburg, Randsburg, Mojave, and Kramer. Cheap electric current is ready for service. It is said that Atolia received its name from the first two letters of Atkins, a well known mining man, and the last four letters of DeGolia, an Italian who shipped tungsten to Germany from the district. Eight high-graders were arrested for stealing tungsten ore last week. A scheelite nugget weighing 142 lb., for which $4 per lb. was offered, was unearthed by Italians 2½ miles from the Atolia mill.

SHASTA COUNTY

Work has been resumed at the Afterthought mine at Ingot. A large copper and zinc plant is to be erected.

TULARE COUNTY

Portersville has added zinc to the list of mineral deposits worked nearby, namely, chrome, granite, magnesite, and manganese. It is reported that an extensive deposit of zinc has been found in the foothills.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—The Onondago Mines Co. is shipping 20 tons of ore per day from development on the 180-ft. level. The vein there is 7 ft. wide; on the 100-ft. level it is 2 ft. wide. A sorting-house and orebins are to be erected at once, also a loading trestle to the company's railroad spur at the mine. The ore yields $9 per ton net, but will be sorted into smelting and milling ore. After enough development has been done, a concentrating mill will be built. The manager, T. Kyner, states that the new compressor plant is giving good results and that the air in the mine is much improved.

The manager of the Imperial mines, H. Butler, reports the cutting of a 14-in. vein of copper pyrite.

The Colorado Central Leasing Co. is making good headway in sampling its dumps. E. S. Wiard is in charge of the work and is satisfied with the value of the samples taken. A 100-ton mill will be erected in Georgetown, and a tramway built to convey the ore from the mine to the mill a distance of two miles.

The Hollingsworth Mining Co. at Silver Plume in March shipped 150 tons of concentrating ore, yielding two cars of 49% zinc concentrate and 6 tons of 60% lead. There is a good deal of gray copper and ruby silver now appearing in the ore, which may necessitate hand-sorting to save this high-grade product.

At the Mendota mine, Silver Plume, Stephens brothers have completed the addition to their concentrating mill, and will now be able to handle the large tonnage of zinc and lead ore they are mining.

Georgetown, April 9.

DOLORES COUNTY

The Emma gold mine in the Cone district has been optioned to the Tonopah Belmont Development Co.

The report of the Rico Wellington Mining Co. for last year states that the output was 11,904 tons $8.88 copper ore, 18,132 tons of $11.69 lead ore, and 629 tons of iron sulphide worth $4 per ton. The revenue from ore sales was $105,573. The cash balance was $3373 at the end of 1915. There was 5985 ft. of development done.

LAKE COUNTY (LEADVILLE)

(Special Correspondence.)—The Derry Ranch Gold Dredging Co.'s boat near Leadville, which has been shut-down during the winter on account of severe climatic conditions, resumed work on April 4. It is expected that the dredge will continue operating through the remainder of the year. This dredge started last fall, and after operating two months, cleaned-up $69,292, which enabled the company to pay a 25% dividend, and still left a good working balance in its treasury.

Leadville, April 7.

SAN JUAN COUNTY

Ore shipments from the Silverton district in March totaled 134 carloads.

Teller County (Cripple Creek)

On April 11 the Roosevelt drainage-tunnel and the main shaft of the Elkton were connected at a point 4 miles from the tunnel portal and a depth of 1640 ft. Rock broken in extending the adit will now be hoisted through this shaft. The flow of water is 14,780 gal. per minute.

IDAHO

Idaho County

Three stamps at the Mineral Zone gold mine near Elk City recovered $2300 from 15 days' run recently. Prospects are said to be favorable. G. L. L. Baskett is in charge.

Shoshone County (Coeur d'Alene)

Wages of Coeur d'Alene miners in April will be $4.50 per day, on account of the high average of lead during March, namely, 7.26c. per pound.

Dividends payable by Coeur d'Alene mines in April total $716,650, making $3,154,435 for the four months.

At the Interstate-Callahan the shaft is being sunk 5 ft. daily on its way to 400 ft. below No. 6 level. A hoist was installed underground at this point. During March there was shipped 600 tons of lead concentrate and 6100 tons of zinc ore and concentrate. The profit was $325,000. The mill is treating 400 tons daily, recovering 92%. A 1200-ton plant is soon to be erected at Enaville. The company's cash on hand and unsettled ore shipments total $500,000.

Development in the Idora is reported to be very good. New Janney flotation machines are being installed in the mill.

To prevent any conflict with the American Smelting & Refining Co., which has a contract until January 31, 1930, for all of the product of the Bunker Hill & Sullivan mines that contains between 30 and 75% lead, the Bunker Hill company, which has begun construction of its smelter near its properties at Kellogg, is planning to eliminate its water concentration system, according to reports, and the only preliminary treatment the ore will receive before going to the reduction plant will be jigging. Ever since the contract with the A. S. & R. Co. was entered into in 1905, when the Bunker Hill company sold its Tacoma smelter to the Guggenheim interests, the entire output of the mines has been reduced to a concentrate that averages about 63% lead and 20 oz. silver per ton. By abandoning water concentration and substituting a jig treatment the product can be reduced to less than 30% lead. This would leave it free to treat the ore in any way it saw fit, provided its final product was higher in grade than 75% in lead. As the Kellogg smelter and refinery will ship nothing but refined lead and silver, there is no ground left on which the A. S. & R. can base a complaint of violation of contract. The composition of the Bunker Hill company's ore is such that it is practically self-fluxing as it comes from the mine, with the addition of a certain amount of lime. It contains a great deal of iron, as is evident from the tailing-dumps at its concentrators, from which the Northport smelter now is obtaining its iron for flux. The quantity of lime required, while large in the aggregate, will be small in comparison with the tonnage of ore treated. The lime will almost certainly be obtained for the present at least from the vicinity of Northport, and probably from a quarry in the neighborhood of that belonging to and supplying the Northport smelter. The practice of the Bunker Hill will in this respect be just the opposite of the Northport plant. Instead of hauling the ore to the flux the Bunker Hill will haul the flux to the ore.

MICHIGAN

The Copper Country

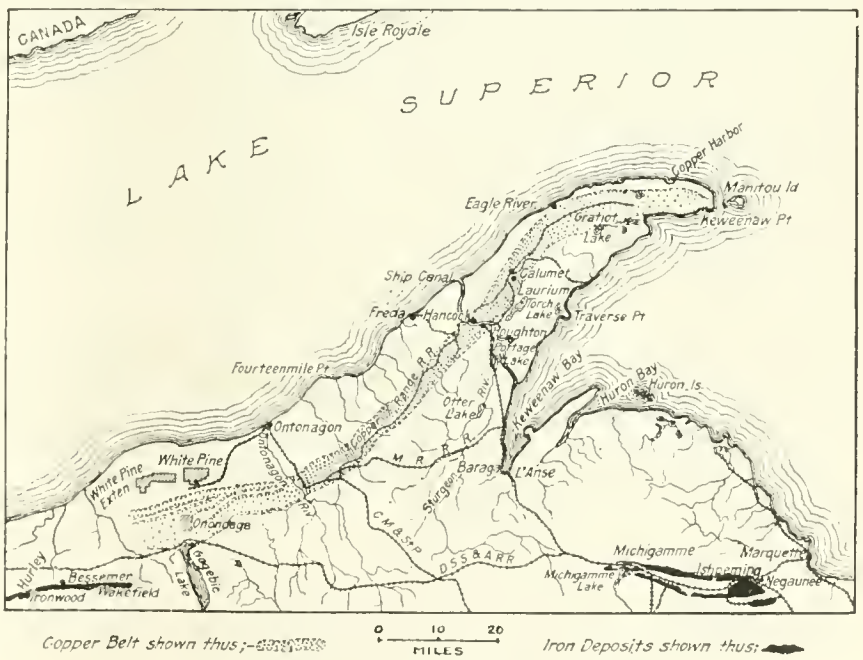
Copper production in March was as follows:

Mine	Pounds	Mine	Pounds
Osceola	1,866,000	Superior	324,000
Ahmeek	2,160,000	Franklin	469,000
Wolverine	550,000	Copper Range	4,300,000
Mohawk	1,340,000	Victoria	200,500
Isle Royale	954,000	Quincy	2,100,000
Calumet & Hecla	6,150,000	Hancock	175,600
Centennial	228,500	Tamarack	684,000
Allouez	935,000	White Pine	385,000
Mass	442,000	La Salle	103,000
		Lake	205,000

There are 18,000 men working in the mines, mills, and smelters of this region, drawing a total monthly wage of $1,500,000. A large number of new accounts have been opened in the local banks.

The White Pine Copper Co.'s output in 1915 (8 months) was 2,824,145 lb. refined copper from 114,039 tons of ore with 67% recovery, an average of 24.76 lb. per ton treated. The cost was 16.64c. per lb. The revenue was $518,318 from copper sold at 18.353c. From the sale of 18,460 shares of preferred stock at $25 was received $461,500. Total expenditure was $705,473. Development covered 8605 ft., against 4721 ft. in 1914. Work at depth is highly encouraging. Sheet-copper, which may become 'mass,' has been found at the contact of shale and sandstone. The tailing, containing high content in copper, is being stored for future treatment by flotation.

Drilling at the White Pine Extension further proves the uniformity of copper content. Shaft-sinking is making five feet daily.



THE COPPER COUNTRY AND TWO OF THE IRON RANGES OF MICHIGAN.

When the shipping season opens on the lakes there will be hardly any copper at docks, metal being dispatched 'Lot' from smelters by rail.

Tamarack shareholders evidently know the value of the Calumet & Hecla offer for their property, and are turning-in holdings for the $59 per share.

Exploration on Isle Royale, the island in Lake Superior, is to commence this spring. Its area is 90,000 acres, a good deal of which has been prospected from time to time. Some time ago it was acquired by Thomas F. Cole and others.

MISSOURI

Jasper County

The ore market at Joplin was stronger during the week ended April 8, the top price for 60% blende being $120, and 80% lead $102.50, while 40% calamine realized $90 per ton. The output of the Missouri-Kansas-Oklahoma region was 7819 tons blende, 352 tons calamine, and 974 tons lead, averaging $106, $82, and $101 per ton respectively. The total value was $960,679.

MONTANA

The returns from 9 months' operation of the State Industrial Accident Board show that the number of accidents is decreasing. There are 1163 employers with about 60,000 men in all industries. Of 4822 accidents 107 were fatal, two catastrophes at Butte swelling the number considerably. Compensation in all forms amounted to $301,450. The Board's expenses in a year were $19,747, covering everything.

Jefferson County

The Crystal Copper Co., recently formed to operate the Crystal mine in the Cataract district, near Basin on the Great Northern line, 30 miles east of Butte, will probably build a mill. W. H. Weed, managing director, recommends this and deep development. About $100,000 will be spent in 1916.

Lewis and Clark County

The *Montana Daily Record* of April 1 contains an interesting description of the Scratch Gravel district, three miles north of Helena, written by R. F. Wilkinson.——Early work consisted of mining silver ore and sluicing for gold.——On the Cruse estate is the Franklin mine, which during the past four years has been re-opened. Its results have been the cause of renewal of interest in the district. From December, 1914, to February, 1916, there has been shipped 137 cars of ore yielding $226,550, and a profit of $145,642. The output is now 600 tons a month. Power is supplied by gasoline engines.——The Scratch Gravel Gold Mining Co. is exploring an extension of the Franklin vein. Its shaft is down 300 ft., where there is 30 in. of ore assaying 2.54 oz. gold and 12.5 oz. silver. The output is 300 tons per month, sent to the East Helena smelter. Walter Larsson is superintendent.——One of the newest syndicates to commence work is the Madden Scratch Gravel Mines Co., whose development is very promising. Rich gold-silver ore was mined years ago.——The Crown Butte mine is operated by the Rival Mining Co. of Portland, Maine. About 2000 tons of $15 ore has been blocked out, and the property is regarded as a valuable one.——The Eastern Belle, Copper Silver Montana, Thomas Flynn, Maverick, Cal. Stevens, G. Gordon, Hermann, Anson, Walsh, Scherrer, Stevens & Kesslers, and Gerry properties are all of merit and are being developed.

Silverbow County

At 1500 ft. in the East Butte, 8 ft. of 6 to 7% copper ore has been cut. In March over 1,300,000 lb. was produced.

During March the Butte & Superior mill treated 56,020 tons of ore, yielding 16,500,000 lb. of zinc in concentrate. The recovery was 92.5%.

The 3000-ft. level of the North Butte mine is opening better than at 2800 ft., especially on the Edith May vein.

Silicious copper ore is required by the British Columbia Copper Co.'s smelter at Greenwood, B. C., and the Bullwhacker company has been asked to supply it regularly.

The Bullwhacker has been leased to J. A. Heilbronner and Patrick Wall, 900,000 out of 1,000,000 shares favoring the transaction. The lessees will operate under the name of East Side Mining Co.

A steam hoist of 4000-ft. capacity, to lift 3½ tons, and costing $50,000 has been ordered by the Davis-Daly from the Nordberg Manufacturing Co. The engine will be ready for work by September.

NEVADA

Humboldt County

An extensive area of copper-gold-silver ore is reported as occurring in the Sonoma range, 5 miles south-east of Winnemucca. The Wolverine Copper Co. is equipping and developing its holdings there.

(Special Correspondence.)—A mining revival in the southern part of this county is predicted. The James Sutherland estate contains the Sutherland antimony mine, in Cole canyon, 15 miles north-west of Lovelock. H. F. Gove has arrived to take charge. By June a large output of antimony is expected.

Lovelock, April 1.

In a winze 50 ft. below 1500 ft. in the Seven Troughs Coalition mine is 8 in. of $2000 ore.

The new development in the cross-cut from the 450-ft. drift in the east vein of the Rochester Mines Co. has proved the greatest discovery ever made in Rochester hill. This cross-cut runs east toward the foot-wall, and has cut through 30 ft. of ore. The last 4½ ft. is estimated at 500 oz., and the last foot shows native silver, assaying over 1000 oz. per ton. Although this has always been referred to as the 450-ft. level, in relation to some of the other workings, the drifts from the bottom of the Codd and Big Four winzes from which this cross-cut is driven are really about 800 ft. on the dip of the vein. Although the mill lost 7 days in March, the output was $42,000.

At the Nevada Packard the mill is treating 110 tons of $10 ore. Mining and milling cost $2.86 per ton.

Lincoln County

At the Prince Consolidated at Pioche is 120,000 tons of tailing in pits assaying 0.11 oz. gold, 10.6 oz. silver, and 6.7% lead, which is to be treated by flotation followed by cyaniding.

Nye County

Through the additional water supply recently obtained the Round Mountain company is sluicing 1750 cu. yd. of gravel daily.

Tonopah mines last week produced 8429 tons of ore worth $176,982. During March the Tonopah Mining Co. produced 7740 tons of $17.30 ore, making a profit of $50,280. Development at 950 ft. in the Rescue-Eula is very encouraging. The output last week, sent to the West End mill, was 206 tons.

Ormsby County

(Special Correspondence.)—Prospecting for copper, silver, lead, and gold deposits is active in the vicinity of Carson City, and several encouraging discoveries have been reported in the past two months. Ten miles south-west of the capital Smith and Foote are developing a free-milling gold claim. The vein is 14 ft. wide, and averages $10 per ton. Streaks assay over $1000 per ton.

The Day mine in Brunswick canyon has been taken under lease by W. Knippenberg. A good quantity of copper ore is exposed, and early shipments are proposed. The property has been developed intermittently for several years.

Art Smith and associates are opening copper-gold ore, some of it high-grade, two miles west of Carson City. Shipments may be started before the close of summer.

Five miles from here a promising silver-lead prospect is being worked by E. Sweetland and M. Smith. Some rich ore has been uncovered, and prospecting is proceeding to determine the extent of the orebody. Many abandoned silver-lead prospects are being re-located and worked.

Carson City, April 5.

OREGON

Josephine County

The Black Eagle property near Grants Pass has been sold by W. S. Neill and others to P. H. Walters, P. Wright, and F. Pirth of Seattle for $175,000. A 50-ton mill is to be erected.

Tungsten ore has been opened three miles above Gold Hill.

UTAH

Juab County

It is proposed by Tintic operators to select a well-situated shaft and sink it to 2500 ft., in order to explore the orebodies below water-level.

The new plant of the Tintic Milling Co. at Silver City is a success, especially the Holt-Dern and Knight-Christensen roasting furnaces.

The Iron Blossom company will pay its quarterly dividend of 10c. per share on April 25. The treasury contains $342,000.

During 1915 the Dragon Consolidated Mining Co. did 2616 ft. of development, with good results. There was shipped 7805 tons of ore, yielding 2560 oz. gold, 102,144 oz. silver, 14,766 lb. lead, and 490,750 lb. copper, realizing $103,899. Cash balance was $38,627, an increase of $35,000.

Salt Lake County

Snow will have disappeared from the American Fork district in a few days, allowing several companies to commence shipping ore.

The Utah Apex averaged 600 tons of ore daily in March, yielding 3,500,000 lb. of lead. Profits are $100,000 per month. The A. S. & R. and U. S. S. R. & M. companies buy the lead and lead-zinc ores. About 400 men are employed.

Summit County

The orebody found in the Daly-Judge mine in January has been opened for 180 ft. by a raise, where it is from 1 to 13 ft. wide. Plans for the electrolytic zinc smelter are complete. The company's name is to be changed to the Judge Mining & Smelting Co., with a capital of 500,000 $1 shares, an increase of $200,000. Flotation is giving better results each month in the mill. The Snake Creek tunnel is in 14,000 ft., up to the Daly-Judge boundary. The present contract is finished, by J. A. McIlwee, and has been accepted. The flow of water is 19 second-feet, or 8628 gal. per minute.

WASHINGTON

The various copper districts tributary to Spokane promise to be operated to capacity this summer, as prices are high and capital is easy to get for development.——In the Chewelah district of Stevens county the United Copper Co. has a 74-stamp mill and flotation plant treating 225 tons per day, employing 90 men. The Security and Copper King companies are busy with exploration.——In the Loon Lake district the Loon Lake Copper Co. is shipping ore.——At Mullan, Idaho, the National is treating ore in its mill, while the Reindeer-Queen and Carney, near-by, will soon be shipping ore.

Stevens County

To treat a large quantity of silver ore at the Deer Trail mine near Turk, a 100-ton mill is to be erected by H. R. Moss, late of Oakland, California, and now of Spokane.

There are 70 men employed at the Electric Point mine, near Northport. The dumps contain over 4000 tons of 60 to 80% lead ore. This is a recently discovered deposit.

CANADA

British Columbia

Dividends payable in April total $277,330, making $1,142,956 for four months.

Ore received at the Trail smelter to the end of March totaled 117,674 tons from over 20 mines.

MEXICO

Hidalgo

The U. S. S. R. & M. Co. reports that on the 1400-ft. level of its Real del Monte mine at Pachuca the shoot is of great length. It assays $30 per ton, and the total silver value is $15,000,000.

PERSONAL

Note: The Editor invites members of the profession to send him particulars of their work and appointments. This information is of unquestioned interest to our readers.

Leslie H. Webb is here.

J. M. Hyde is at Denver.

S. F. Shaw is at Ely, Nevada.

P. H. Argall is at Silver City, New Mexico.

James E. Jopling of Michigan is at Boston.

F. H. Minard has been examining mines in Colorado.

James S. Wroth has left New York for Santiago, Chile.

F. R. Weekes is in California on professional business.

R. B. Wallace has removed from Republic, Michigan, to Gwinn.

Russ M. Hess has returned from Ecuador to Stoddard, Arizona.

C. H. Poirier, manager of the Vipond mine at Porcupine, is in New York.

J. H. Smith, Jr., recently at Cerro de Pasco, has gone to Melones, California.

R. B. Watson, managing director of the Nipissing mine at Cobalt, is at Oatman.

K. C. Li sails today on the *Chinyo Maru* from San Francisco on his return to China.

O. H. Fairchild has been appointed manager of the Ramage mines at Joplin, Missouri.

Henry M. Payne, of New York, has been lecturing on alluvial mining at the University of Utah.

G. W. McDaniel, field engineer for the Tonopah Mining Co., has returned from northern Canada to Tonopah.

W. H. Landers returned to New Almaden on April 15 from Nevada and left on the 19th for Black Butte, Oregon.

W. E. Segsworth of Toronto is preparing to close the Seneca-Superior mine at Cobalt, of which he is managing director.

H. E. Jackman of Rochester, New York, is president of the National Mines Co., Ltd., which will explore the King Edward mine at Cobalt.

Lewis A. Levensaler, formerly field engineer for the Tacoma Smelting Co., is now connected with the Tacoma Exploration Co. of Tacoma, Washington.

Frederick G. Clapp, managing geologist of the petroleum division of the Associated Geological Engineers, has removed his headquarters from Pittsburg to New York.

A. H. Brown has resigned as manager for the Hudson Bay Mines of Cobalt, and of the Dome Lake Mining & Milling Co. of South Porcupine, and is now at his home at London, Ontario.

Robert Sterling, who for the past two years has been chief engineer for the Goldfield Consolidated Mines Co., has gone to Colorado as assistant manager for the Primos Chemical Co., at Vanadium, San Miguel county.

A party of the Associated Geological Engineers of New York, consisting of Myron L. Fuller, Frank A. Herald, and Ralph W. Richards, is conducting geological investigations in northern Oklahoma and southern Kansas.

Guy C. Riddell, about 10 years superintendent of the East Helena lead smelter of the American Smelting & Refining Co., has resigned to become a director of the Montana Ranches Syndicate, of which he has recently been made a vice-president.

Donald M. Liddell, for several years managing editor of the *Engineering and Mining Journal*, has resigned, and is now consulting engineer with Merrill, Lynch & Co., 7 Wall Street, New York. Percy E. Barbour succeeds Mr. Liddell as managing editor.

The Pacific Coast division of the American Association for the Advancement of Science meets at San Diego between August 9 and 12. Some interesting addresses will be given. Albert L. Barrows is secretary, at the University of California.

THE METAL MARKET

METAL PRICES

San Francisco, April 18.

Antimony, cents per pound	44
Electrolytic copper, cents per pound	29
Pig lead, cents per pound	$8.00—8.80
Platinum: soft metal, per ounce	$88
Platinum, hard metal, 10% iridium, per ounce	$92
Quicksilver, per flask of 75 lb	$136
Spelter, cents per pound	22
Tin, cents per pound	46
Zinc-dust, cents per pound	30

A consular report from Cartagena, Colombia, S. A., states that the monthly output of platinum is over 1500 oz. per month by independent producers.

ORE PRICES

San Francisco, April 18.

Antimony: 50% product, per unit, of 1%, or 20 lb	$2.25
Chrome: 40% and over, f.o.b. cars California, per ton	12.50
Magnesite: crude, per ton, f.o.b.	8.00
Magnesite: plastic, no iron and lime, calcined, ton	25.00—30.00
Magnesite: refractory, 11% iron, dead-burned, ton	35.00
Manganese: 50% metal, 8% silica, per ton	12.00
Tungsten: 60% WO_3 per unit of 20 lb	65.00—75.00
Vanadium: 10% vanadic oxide, per lb	0.50

All tungsten buyers at Boulder, Colorado, are paying $75 per unit, with no premiums.

Tungsten: A New York dealer writes: "Though reports from Colorado and Nevada quote around $100 per unit, I have been unable to find any buyers above $85 for prompt delivery, New York; and it seems extraordinary that the biggest buyers in this country should pay the high figures in Colorado and not be prepared to accept material at 15% lower in New York. Forward tungsten has again changed hands at $78, and business for shipment as far ahead as July and August has been contracted around $70 per unit."

Chromic iron ore production of the United States in 1915 was 3281 tons, worth $36,714, against 591 tons and $8715 in 1914.

EASTERN METAL MARKET

(By wire from New York.)

April 18.—Copper is quieter but strong; lead has an easier tendency; spelter is steady and quiet.

COPPER

Prices of electrolytic in New York, in cents per pound.

The closeness of the China exchange to parity, the absence of free selling from the United States, the mintage by Japan on account of Russia, and the extension of the area in which the Indian rupee has to do duty, namely Mesopotamia, Egypt, and East Africa, as well as the re-adjustment of currency in India itself, create a feeling of confidence as to the future of the silver market, according to Samuel Montagu & Co. of London.

Last week the Nipissing shipped 269,399 oz. to London.

On April 20 the Nipissing pays a dividend of $100,000, making $11,010,000 to date. The company has $311,917 bullion on hand, also $553,597 ore and bullion.

Silver produced by the A. S. & R. Co. in 1915 was valued at $38,007,727, there being 76,117,453 oz. refined. The U. S. S. R. & M. Co. produced 12,218,246 ounces.

Eastern Metal Market

New York, April 12.

The past few days brought a renewal of the record buying by the British and French governments, and it is now estimated that 200,000,000 to 250,000,000 lb. of copper has been taken for delivery over the balance of this year and early part of 1917. As was expected, domestic consumers got in line, and also bought heavily. Prices advanced under the stimulus, and 28c., full terms, is quoted for July and August delivery of electrolytic. Lake is held at about 29c., future delivery, although some of its producers are out of the market. Zinc is on the upward trend as a result of moderate but steady buying. Lead is weaker, the 8c. level having been broken; and it is apparent that domestic consumers are holding off for cheaper metal. Tin is higher, following a rather active week. Antimony is lower as a result of there being larger supplies in sight. Aluminum is unchanged, and its quotations are nominal.

The prices of most steel products appear to have reached their crest, but pig-iron is showing additional strength. Buying is less feverish in many directions. The steel mills are filled with orders for months to come, and most of them will welcome an opportunity to shorten their deliveries. The demand for metal-working machinery is good, although the orders are not large individually. They are of a healthy character, however, coming as they do from scattered sources. Buyers of machine-tools are no longer buying without giving proper consideration to their needs, and they show a willingness to wait, if needs be, to get the tool best fitted to their necessities. In short, the great rush of buying equipment for manufacturing war supplies is now well past.

COPPER

Following the tremendous buying of early last week there came a lull, although the market was by no means at a standstill, and prices continued firm. On Monday of this week buying for export started again with a rush, and the demand has been so great that quotations were advanced on all sides though not uniformly. Yesterday (March 11) at the end of the second day of the second big movement electrolytic could not be obtained for July and August delivery under 28c., 30 days, delivered, or 27.87½c., cash, while May and June was quoted at 28.75 to 29c. What prompt deliveries would bring is problematical. Lake, on which early delivery cannot be bad, is quoted at 29c. Estimates place the amount of copper taken by Great Britain and France in the past few days at 200,000,000 to 250,000,000 lb., and the end is not yet, for buying in behalf of Russia and Italy is expected. As was to be expected, the heavy foreign buying roused domestic consumers to activity, and they have taken large quantities also. The big export orders are reported to have been divided among the A. S. & R., Calumet & Hecla, and United Metals Selling companies. While no authorized statement has been made concerning the prices paid, they are understood to have been under the current market, in view of their exceptional character. The London market became easier late last week, dropping to £134. As will be remembered the London electrolytic price stood at £136 for weeks. Exports up to, and including April 11, totaled 7017 tons. New England consumers of copper and other metals are still in a bad way because of the freight congestion in that territory. Many of the smaller metal-working plants there have shut-down for want of material. Relief for some points is promised after April 14, as on midnight of that day the embargo, export excepted, will be partly raised. The embargo will remain in force, however, against Naugatuck, Waterbury, Waterville, Torrington, Bristol, New Britain, and Hartford, all great metal-consuming centres. The Remington Arms & Ammunition Co., at Bridgeport, and the Winchester Repeating Arms Co., at New Haven, have partly solved their freight difficulties by establishing their own steamboat lines across Long Island sound, thereby gaining access to the line of the Long Island railroad, which connects with those of the Pennsylvania and other lines. The Calumet & Hecla recently shipped 50,000 lb. of copper to the East by express.

ZINC

The market has been moderately active, although a good part of the buying is said to have been on the part of dealers who anticipate a stronger market. The brass mills have been the chief buyers. Although the galvanizers are known to be insufficiently covered they are unwilling to buy at present prices, but some of them will be forced into the market in the near future. Prompt and April spelter was quoted yesterday at about 19c., New York, and 18.75c., St. Louis. May delivery is quoted at 18c., New York; June, 17.75c., St. Louis; and third quarter at 16.25 to 16.50c., St. Louis. It will be observed that prices have advanced in the past week. Business should become more active in view of the heavy buying of copper, and the better freight conditions in New England. Sheet zinc is unchanged at 25c., carload lots, f.o.b. mill, 8% discount for cash. The London quotation for spot zinc, April 11, was £98. Exports of spelter, April 1 to 11, totaled 1015 tons.

LEAD

This metal has been dull throughout the past week. The export demand has tapered off, and domestic consumers are inclined to wait for lower prices. They are carrying stocks as small as they dare. The A. S. & R. Co. continues to quote 7.50c., New York, and 7.42½c., St. Louis, but this price only serves to establish the average at which the company sells to those with whom it has contracts. Some of the independents, who perhaps are not over-anxious to sell because of their sold-up condition, have adhered to 8c., both at New York and St. Louis, while others have dropped under the 8c. level. It is reported that down to 7.75c., New York, could be done, but it is said that lead at this price is difficult to find. The average of prices, as quoted by the independents is 7.87½c., New York or St. Louis. Some large foreign inquiries have been before the trade in the past week, but they have not resulted in business. On one of these 8.25c. was quoted, and it is intimated that the producers are more anxious for domestic business than they are for foreign. Exports in the first 11 days of this month totaled only 155 tons. The London quotation on the 11th was £34 5s.

TIN

Tin is higher than it was a week ago; the quotation for spot yesterday (the 11th) was 53c., but on the 5th it was up to 55c. A large business has been done in the past few days, principally in tin afloat and futures, one buyer taking 300 tons, April 7. Tin in London continues an uncertain quantity because of the possibility of shipping licenses being refused. Metal actually afloat therefore commands a premium, as it is certain of delivery unless the ship sinks. Yesterday and today the market has been dull, and some pressure to sell prompt is developing. Up to yesterday 675 tons had arrived this month, and there was afloat 5389 tons. The A. S. & R. Co. has received additional shipments of Bolivian tin concentrate.

ANTIMONY

Prompt Chinese and Japanese antimony is easier at 42.50 to 43c., because of the larger supplies near at hand, though it is admitted that it is difficult for the dealers to actually get some of this metal into their possession.

COMPANY REPORTS

OLD DOMINION COPPER MINING & SMELTING CO
UNITED GLOBE MINES CO.
OLD DOMINION CO.

These three companies must be considered together, as the first two are operating companies controlled by the Old Dominion Co. Work is done at Globe, Arizona, and the reports are for 1915.

At the Old Dominion mine the west side orebodies produced 75% of the smelting ore. No. 14 level contributing one-third. At No. 17 and 18 the lode is 35 and 40 ft. wide, respectively, all concentrating ore. Encouraging results were reported from the east side orebodies. Development totaled 11,341 ft., a decrease of 1324 ft. Mining cost $5.51, an increase of 31c. per ton. Abnormal rain resulted in as much as 13,000,000 gal. per day being pumped in February. In March more water broke through the dacite capping above No. 12 level, resulting in

OLD DOMINION MINE, MILL, AND SMELTER.

No. 18 and 16 levels being flooded, and mining suspended for five weeks. All this made extra work and costs. A total of 2,769,400,000 gal. was pumped, compared with 1,349,210,000 in 1914. Of this, 730,000,000 gal. was sold to the Miami Copper Co. The minimum flow was 5,360,147 gal. on October 28, and maximum 14,492,923 gal. on March 26. I. H. Barkdoll is mine superintendent.

The mill treated 173,046 tons of 4.34% ore, 140,480 of which was custom ore, mostly from the United Globe mine, at a cost of $1.215 per ton, an increase of 28.3c. The recovery was 85.27%, an increase of 12.72%. Oil flotation gave good results.

The smelter reduced 206,549 tons of charge, almost the same as in 1914, at $2.755 per ton. The converters yielded 27,736,158 lb. fine copper, at a cost of $5.36 per ton of metal, a decrease of 29c. After 30 months, making 70,860,000 lb. of copper bullion, the converter was removed for repairs, a remarkable record.

Old Dominion metals, namely, 13,771,681 lb. copper, 40,633 oz. silver, and 621 oz. gold realized $2,595,431. Profit in treating custom ore, etc., was $259,415, making a total of $2,854,846. The net profit was $1,337,086, plus $967,293, balance from 1914, a total of $2,304,379. Dividends absorbed $810,000, and depreciation, $767,375, leaving a surplus of $726,852 for 1916. The total cost per pound of fine copper was 8.9 cents.

In the United Globe, development amounted to 9011 ft. The orebody between No. 10 and 12 levels opened splendidly, with a maximum width of 45 ft. The Kingdon shaft was sunk to No. 16 level from the 14th. It is to be completely equipped in 1916, to allow all Old Dominion and United Globe ore to be hoisted in case of trouble at the A shaft. Several dumps were cleaned up during the year. Smelting oxide and sulphide and concentrating ores shipped to the Old Dominion plants totaled 141,240 tons, averaging 4.08% copper. The yield was 11,536,021 lb. copper, 105,110 oz. silver, and 1509 oz. gold. Total revenue was $1,454,324. Adding the profit, $812,251, to the 1914 balance, $239,598, there was $1,051,849 available. Dividends totaled $621,000, and depreciation $152,380, leaving a surplus of $277,469 for 1916.

The Old Dominion Co.'s income from dividends, etc., in the above companies was $1,405,296. Of this, $1,466,765 was distributed. The 1914 balance was $433,065, and that for 1916, $355,696.

MARY MURPHY GOLD MINING CO.

This company operates at Romley, Chaffee county, Colorado, and the general manager, George E. Collins, reports for the past year as follows:

Development in five claims totaled 7248 ft., at a cost of $7.22 per foot. A considerable tonnage of ore was opened, but less than sufficient to make up for that extracted. A good deal of the ore being mined at present is only rendered workable by high metal prices. Reserves of broken ore are 12,000 tons for the mill, and 100 tons for the smelter, estimated to yield $125,000 and $3000 net, respectively. There is enough ore for the mill for 6 to 12 months. Underground work cost $3.21 per ton. The aerial tramways worked well, and cost 12c. per ton. The mill treated 57,810 tons at a cost of $1.99 per ton, producing 1925 tons of lead, 1741 tons of iron-copper, and 4700 tons of zinc concentrates worth $539,524. Bullion was worth $614, crude ore $61,076, and tributers' crude ore $38,931. The total was $640,144, against $300,010 in 1914. Flotation of the slime was a success, and increased the quantity of zinc recovered. The ore is very complex and difficult to treat.

All costs amounted to $5.56 per ton, an increase of 18c., due mainly to mining. The total profit from all sources was $281,197, less $47,121 for depreciation and $13,660 for interest. Dividends were $50,134. It has been decided to set aside $110,000 for buying or developing a new property, search for which is now under way.

SENECA-SUPERIOR SILVER MINES, LIMITED

In spite of higher prices for explosives, steel, and mining supplies of all kinds, this Cobalt, Ontario, company extracted silver at 23.45c. per oz., in 1915, a reduction of 7.08c. To do this, exploration (1152 ft.) was curtailed, and broken ore in stopes was sent to the mill. Development did not disclose any new orebodies. Fifteen feet below the collar the winze below the fourth level entered the Keewatin formation. Ore continued in this for 45 ft. The shoot below No. 5 is short and low grade.

The manager, R. H. Lyman, states that the mill treated 25,194 tons. Concentrate shipped was 1014 tons. The production from all sources was 2,047,150 oz. silver, making 5,001,870 oz. to date.

The silver sold at 51.29c. per oz., a decrease of 1.93c. The profit was $569,991. Six dividends amounted to $335,219. The balance for 1916 was $306,586, against $71,814 carried forward to 1915.

AMERICAN TELEPHONE & TELEGRAPH CO.

A recent writer said that Americans show their appreciation of the telephone and automobile by wanting these appliances to annihilate space, as it were. The report of this great company for 1915 proves what an enormous business is done by wire. At the end of 1915 there were 9,151,221 stations, an increase of 502,228, using 18,505,545 miles of wire. Of this length, 93% is copper wire. There is 10,536,837 miles underground, costing with conduits, $205,700,000. The gross revenue of the 'Bell' system, including the A. T. & T. Co., was $239,909,649, a gain of $13,957,526. After paying everything, including interest, the net result was $48,086,114, of which $32,897,065 was paid in dividends. Mines and metal producers should be interested in these notes.

MINING DECISIONS

Oil-Placer—Validity

A placer-oil location made in good faith by an association of persons who subsequently formed themselves into a corporation for the purpose of developing the property, each owning stock in the corporation, to which the location is conveyed, in proportion to his interest in the claim, is not invalid, there being no evidence that such location was made in the interest of and with a view to enabling the corporation to acquire a greater area of mineral ground than may lawfully be embraced in a single location by a corporation.

McKittrick Oil Co. (Land Department), 44 Land Decisions, 340. August 30, 1915.

Agreement to Lease—Same Effect as a Lease

Where an agreement to lease for a valuable consideration all the iron ore under certain lands provided for the payment of royalties on minimum ore shipments, and thereafter the lessee entered into possession and expended about $70,000 in development of the property, the agreement was held to have become a valid-executory contract, notwithstanding the fact that it was in form an agreement to lease rather than an executed lease. The lessee was held liable for the minimum royalties due and for those which should thereafter become due, and could not be relieved from such liability by an assignment of his interest (without the lessor's assent) to a third party.

Hairston *v.* Hill (Virginia), 87 Southeastern, 573. January 13, 1916.

Mining Lease—Surface Rights Adjusted

Where the manager of a mining corporation who knew that his principal, the lessee, had modified the contract with the lessor as to the taking of timber from the surface of the ground, continued in the service of the assignee of the lessee, the assignee was charged with said manager's knowledge of the existence and terms of the original agreement. Said assignee, although entitled under the lease to the use of surface ground upon which to build houses for its employees, may not use the portions of the land devoted to agricultural purposes by the lessor where there is other ground available for building sites. On the other hand, the lessor is prohibited from polluting a stream which supplies water for the boilers used in the lessee's mining operations.

Blue Grass Coal Corporation *v.* Combs (Kentucky), 182 Southwestern, 207. February 11, 1916.

Oil Lands Within Withdrawal—Not to be Patented.

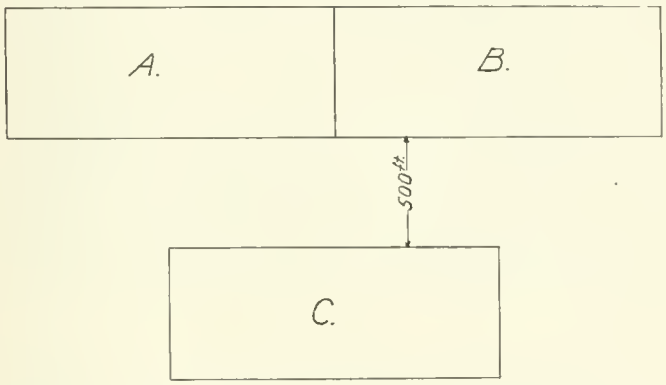
No title is acquired under or by virtue of a school indemnity selection until the same has been approved by the Secretary of the Interior, and where the selected lands are classified as petroleum in character, withdrawn and placed within a petroleum reserve, the Secretary is without authority to approve the selection for unconditional patent, nor will the State's grantee in such event be protected as a "person who has in good faith located, selected, entered, or purchased * * * under the non-mineral land laws of the United States, any lands which are subsequently withdrawn, etc," as provided in Section 3 of the Act of July 17, 1914, because the land under consideration was in a Naval Petroleum Reserve and hence dedicated to a public use.

State of California *et al.* (Land Department), 44 Land Decisions, 127. June 23, 1915.

Note: The same rule was applied even after proof of character, payment of purchase money, and issuance of receipt in Thomas J. Stockley, 44 Land Decisions, 178. July 9, 1915.

Question: A and B are two claims in Alaska that were incorporated; stock was sold and work was done on them before March 1913. Subsequently the claim C was located, and since then the work has been concentrated on the new claim, namely C, to the neglect of both A and B. Are these two claims subject to re-location; also, what becomes of any improvements that were left on A and B?

Answer: We assume that what our correspondent means by the statement that the "claims were incorporated" is that a corporation was formed which took over the ownership of the claims. We assume that the claim C was also located by or in the interest of the corporation. Under such circumstances all of the $300 worth of annual labor can be performed on the claim C, provided such work satisfies the requirement that it shall result in an actual benefit to the other claims. Whether group



work of this character performed on one claim will satisfy this requirement is always a question of fact. In the diagram submitted by our correspondent, claim C is separated by some intervening distance from the other claims. In jurisdictions like California where the condemnation of private rights of way for mining purposes is not permissible, the objection might be made that work on claim C would not benefit claims A and B because of this intervening space, which might be controlled by a third party who could then prevent any workings from C from being driven across into claims A and B. Frequently the rule is stated that the claim upon which group-work is performed must be one of a contiguous group. The reason for this rule would cease to exist, however, in these jurisdictions where a private right of way for mining can be condemned or where a right of way was secured by contract, etc. If claims A and B were actually abandoned or forfeited the improvements situated thereon would revert to the public domain as a part of the claims themselves, and would become the property of a re-locator. There may be exceptions to this rule arising out of the peculiar circumstances of the case. In the absence of such exceptional circumstances the general rule would apply.

If an applicant for mineral patent withdraws his application because of a protest, any subsequent application filed by him for the same land must be considered in the light of the previous testimony.

BOOK REVIEWS

Web of Steel. By Cyrus Townsend Brady and Cyrus Townsend Brady, Jr. P. 336. Illustrated. Fleming H. Revell Co., New York, 1916. Price, $1.25.

After we had started to read this book, we stayed up late in order to finish it. The tale is absorbing. If the book was meant to interest and excite, it is an unquestioned success. But it does more, it exemplifies the value of accuracy (that is, science) in the work of the engineer. The first half of the story hinges upon the building of a big cantilever bridge, which fails at the last moment owing to an error of calculation in the design. The main strut, 60 ft. long, proved too weak to carry the stress. The bridge collapsed, killing 150 men at work upon it. The hero, a young man who had criticized the work of the chief engineer, his father, and had yielded to his senior's superior judgment, insists on taking the blame for the blunder; he sacrifices himself out of love for his father and the father's reputation. By assuming the blame he loses the chance of marrying the heroine, who is the bridge-building company's president's daughter. So we have a love tale intermeshed with the web of steel. In the second half of the book a dam is being built in Arizona and again engineering ideas come into play; this time in such a manner as to restore the hero to honor and to his beloved. It is well done. One feature of the book is particularly commendable: drawings and diagrams explaining the engineering details, making them intelligible to the non-technical and all the more convincing to the technical. In short, it is a book that an engineer will enjoy. The authors have achieved their purpose.—T. A. R.

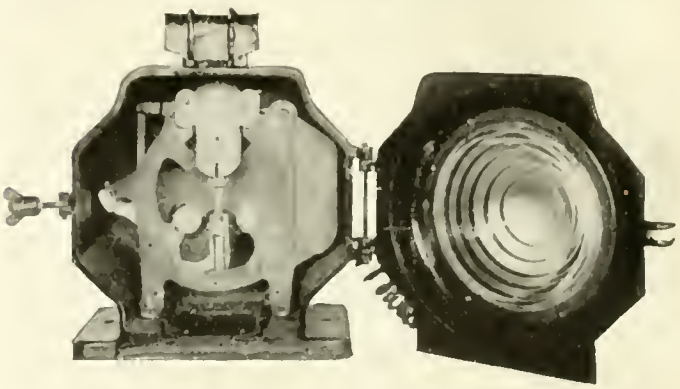
Metallurgists' and Chemists' Handbook. (4 by 7 inches.) Compiled by Donald M. Liddell. P. 603. Ill., index. McGraw-Hill Book Co., Inc., New York, 1916. For sale by the Mining and Scientific Press. Price, $4.

The author of this excellent volume will be remembered from his connection with, and the number of instructive articles he wrote for the *Engineering and Mining Journal*. A cursory glance at the book at once tells the student that it is worth while. Much of the data and many tables are not exactly new, but they have been corrected as far as new values were obtainable. The first section of 52 pages, entitled 'Mathematics,' covers far more tables than usually found in similar works. Metallurgical price and production statistics cover the past 10 years in the important metals (although those for 1915 are not given), also the output and consumption of these. Physical constants occupy 158 pages, dealing with laws of physics, temperature, specific gravity, evaporation, power transmission, hardness of materials, the principal concentrating ores and gangues, gases, and inorganic compounds. Seventy pages are devoted to chemical data, such as laws, the periodic table, atomic weights, brief notes on the common metals and metalloids, detection of the metals (field tests), acids, heat of formation carbonates, sulphides, etc., and the electro-chemical order of the elements. The author is on his special ground when considering sampling, assaying, and analysis. Metallurgists will turn to ore-dressing and cyanidation, and will find more on flotation than on cyanidation, showing the trend of events. The processes and flotation oils are briefly discussed. In the 64 pages on ore-dressing, all types of crushing, grinding, and concentrating machines are described. Coals and oils and refractory materials form a useful chapter. The mechanical engineering and construction section is replete with practical hints, including belt-conveyors, pipe-fittings, rope-knots, and cost of constructing plants. General metallurgy, 108 pages, is simply crowded with notes on every subject coming under this head. First-aid and a good index complete a valuable compilation.

INDUSTRIAL NOTES

Mine-Locomotive Head-Lights

In large well-equipped mines electric locomotives are frequently used for gathering and long hauls. A strong head-light is of great importance for the motor man, and is a warning to miners who get on the track. The new compensation acts make it to the mine operator's advantage to have such illumination. A thorough investigation of mine lighting, including head-lights, has been undertaken by the General Electric Co., resulting in the design of a complete series of loco head-lights. A recent circular on the subject, by P. S. Bailey, is replete with descriptions, photos, and charts, and is of considerable interest. The accompanying photo will give an idea of the manner in which the frame and mechanism of the head-lights are positioned in the casing; the elements of the electrode, link, and lever mechanism being in view, while the magnet is mounted in the rear of the magnetic shield which prevents any deterrent magnetic influence caused by stray flux from the magnet, from interfering with the operation of the arc. The lower electrode consists of a hollow cylinder of sheet-iron rolled up and welded, plugged at one end and filled with a mixture of certain oxides which produce the highly luminous arc. The tube when filled is capped with a metal-disk, and the edges spun over to hold same in position. When the arc is struck the disc burns away rapidly, and the electrode is self-sealing.



INTERIOR VIEW OF HEAD-LIGHT.

Pearson, Peppard & Co. have opened offices in the Woolworth building, New York, to conduct a general business in brass and copper rolling-mill products, steel, and steel products. Both members of the firm have been closely associated with the metal business for several years, in mill products and virgin metals, such as tin, copper, lead, spelter, antimony, aluminum, etc.

Six switching locomotives made by the American Locomotive Co., thirty-six 20-yard all steel automatic-range type Kilbourne & Jacobs dump-cars, and three Osgood special 105-ton shovels are being supplied the Calumet & Arizona Mining Co. by Norman B. Livermore & Co. of San Francisco.

To 'brighten' oxidized gold which will not amalgamate on its dredges, the Natomas company installed a 4½-ft. Hardinge mill on No. 7 dredge. Results are entirely satisfactory, and six more mills are to be installed on some of the other boats of the company.

The Roessler & Hasslacher Chemical Co. announces that its peroxide of sodium plant at Niagara Falls was burned early in March, and deliveries will be made again by May 1.

EDITORIAL

T. A. RICKARD, Editor

WHEN his neighbor's house was burning, he began to think of insurance. Even then some of his friends told him not to be in a hurry, so he started a conversazione on the subject, regardless of the sparks that were flying overhead in the gathering gloom. Gentlemen, preparedness is already belated.

CONTINUOUS decantation as applied to cyanidation in the Comacaran mill, in Salvador, is described by Mr. A. B. Peckham in this issue. The article has the merit, among others, of stating frankly both the bad and the good points of this practice, and it can be read therefore with confidence.

ELECTROLYTIC precipitation is a subject of which much is yet to be learned. To that end we are glad to publish an account of the experience obtained at the Minas Prietas mines in Mexico, by Mr. P. H. Crawford, supplementing the information given by Mr. G. H. Clevenger in the comprehensive article appearing in our issue of November 13, 1915.

REFERRING to the Cottonwood and American Fork mining districts in Utah, where an insistent demand has arisen for an investigation by the U. S. Geological Survey, as mentioned in our issue of the 15th instant, we note that the Director, Mr. George Otis Smith, has responded favorably, promising to undertake the work just as soon as the Sundry Civil Appropriation bill has been passed by Congress.

NEW DECREES affecting mining are announced from Mexico City, the Carranza government having issued regulations meant to discourage large holdings of undeveloped claims by imposing a prohibitive tax; but until we know for certain who is to govern Mexico, it is not necessary to inquire closely into such attempts to regulate mining operations. At the present time there is as much doubt as to who will collect the taxes a month hence as there is regarding their incidence.

ZINC smelting in Great Britain has received some measure of Government support at last, the Munitions Department having arranged with the smelting companies to deduct from their excess profit, before taxation, the difference between cost of new construction during the War and before; also a "reward" is to be given for extending their plant, in the form of an allowance of 50% on such cost of construction to be deducted from excess profit before taxation. This is not likely to induce the erection of any large new zinc-smelting works, but it will cause several of the existing small smelters to enlarge their capacity. We note also that all the Broken Hill companies, except the Sulphide Corporation and the British Broken Hill Proprietary, have signed a 50-year contract with the Associated Smelters for the smelting, refining, and realization of all their zinc and lead concentrates. These arrangements will have their effect on the spelter market in due course.

ON April 12 a great Cornishman passed away: Joseph Henry Collins. He died at the fine old age of 74, with his faculties fully alert and with his harness on. One of the pioneers of technical education in Cornwall, an eager student of the sciences applied to mining, a keen observer, and a consistent exponent of the best Cornish traditions, his leaving makes a big void. Some snob said that Robert Boyle was the father of modern chemistry and the nephew of the Earl of Cork; J. H. Collins was the grandfather of technology in Cornwall and the father of four good mining engineers.

COST of living has been rising steadily since September, the increase since then being equal to 18%. The average price of the principal commodities at the present time is the highest on record. At a period when thrift is desirable and sober thought an obvious necessity, New York is the scene of an orgy of dissipation and extravagance worthy of a drunken sailor. The War has given excess of wealth to a lot of ignorant people and furnished them with the opportunity to disgrace this democracy. Whatever we may think about the rights and wrongs of the great contest in Europe, we may well be sobered by the hearing of so much horror and the sight of so much pain among the civilized peoples from which we, all of us, have originated.

APPARENTLY the organization of a group of New York capitalists, under the name of the American Rand Syndicate, to acquire property on the Witwatersrand meets with cordial approval in London. Mr. Isaac Lewis, of Lewis & Marks, is felicitated on his success in getting the firm of Adolph Lewisohn & Sons to head the new departure. Complimentary remarks are made concerning Mr. W. W. Mein and his coadjutors, now on the ground and commencing their examination. The property to be investigated first is the Grootvlei, belonging to the Grootvlei Proprietary Mines, having 361,850 shares issued, of which 253,020 are held by the East Rand Mining Estates. The property adjoins the Geduld, Springs Mines, and Daggafontein. Indeed, it is just east of the most promising part of the Rand, known as

the Far East, and containing such famous mines as the Modderfontein and Brakpan. The Grootvlei is a big property, covering 1135 claims or about 1707 acres. The ground has been prospected in a preliminary way, by bore-holes, the Van Ryn reef having been cut at 3340 and 4040 feet on the western boundary and at 2500 feet vertically on the east side. Two shafts were started in 1909, but they were abandoned at depths of 55 and 378 feet, respectively, owing to an inrush of water. The Union Government owns about 80,000 claims in the same locality, so that there is ample scope for prospecting and for new ventures. However, the men who have taken the matter in hand are no tenderfeet and the engineers acting for them are familiar with local conditions, so we expect to see the business tackled on a workmanlike basis.

IN this issue, Mr. Corey C. Brayton has contributed an excellent paper on prospecting and dredging near Nome, a record of recent experience in that sub-Arctic region. In particular he discusses types of machines adapted to the local conditions, which differ widely from those obtaining in regions nearer home. He makes it clear that dredging on the Seward Peninsula is conducted on small rich areas of loose gravel that will last a 2½-ft. bucket-dredge from 12 to 18 months of working time, while the season for productive operations is only four months. Disregard of basic facts explains the failure of several dredges on the coastal plain behind Nome. As to the cost of labor and freight, he says with much truth that "the difficulties of operating in Alaska in general and on Seward Peninsula in particular are always magnified; difficulties mean high cost but not necessarily prohibitive cost." The account of the development and operation of the light prospecting-drill and the flume-dredge are particularly timely, having regard to the near approach of another season.

DISCUSSION this week exhibits its customary variety of interest. Flotation is to the fore in the shape of a contribution by Mr. O. C. Ralston, who continues the useful analysis of the basic principles of the process as outlined by Mr. C. T. Durell and himself. Such scientific controversy, with its free give and take, constructive criticism and friendly comment, is of the greatest usefulness in clarifying ideas and removing misconceptions before advancing to new developments. Messrs. Durell and Ralston furnish a good example of criticism that can be penetrating yet polite. In another part of this issue we give a short article by Mr. L. A. Delano describing flotation practice on the lead ores of south-eastern Missouri. The working details should prove suggestive to other operators. The second contribution to discussion refers to the platinum deposit at Boss Springs, Nevada. This is written by Mr. Adolph Knopf, who wrote the excellent geologic diagnosis published by the U. S. Geological Survey, abstracted in our issue of June 5. Our recent editorial on 'Mine Accident Insurance' elicited a rejoinder from Mr. Will J. French, representing the State Commission; now we are enabled to present the other side of the controversy as it appears to the California Metal Producers Association, of which a distinguished engineer, Mr. Albert Burch, is president.

MEN of the 'blue and gold' all over the world will be glad to learn that Mr. Frank H. Probert has been appointed the Professor of Mining in the University of California. The profession generally will approve the selection. It is known that since the death of Professor Christy, in December 1914, the chair of mining has not been filled, save by temporary appointees, and it is fair to say that the authorities found it difficult to make a satisfactory selection. Mr. Probert was not among the applicants nor among those suggested for the appointment last year. In February he delivered a short course of lectures and made so favorable an impression that it led to his being considered as a professorial possibility. Enquiry into his career proved a decisive factor. For those who are not informed on the matter and who will be interested, more particularly the alumni of the University, we may state that Mr. Probert is an Englishman by birth, he will be 40 in a few weeks, he had a distinguished scholastic record, winning several scholarships at the St. Olave's Grammar School and at the Royal College of Science. In 1897 he graduated from the Royal School of Mines, London. Since then he has had an interesting and successful professional career as manager of mines and mining geologist, in Canada, Germany, Spain, and in this country. In 1901 he came to the United States, on the suggestion of Mr. James Douglas, to conduct research in the hydro-metallurgy of copper ores at Morenci, Arizona. In later years he has been doing the work of a consulting mining engineer in the West, notably Arizona and Montana. His numerous contributions to technical literature indicate the ability to explain and expound. During the last few months we have had the pleasure of publishing more than one of his writings, and at an early date we shall give our readers a series of articles by him on the surficial indications of copper, the subject on which he lectured recently at both of the Californian universities, at Berkeley and Palo Alto.

DREDGING on a large scale is to be introduced on the property of the Lena Goldfields in the Bodaibo district of Siberia. This will be done on the advice of Mr. W. E. Thorne, endorsed by Mr. C. W. Purington. The selection and designing of the dredges has been delegated to Mr. Henry M. Payne. During the year 1914-1915 the output consisted of 902,459 cubic yards of gravel yielding gold to the value of £1,782,886, or $8,647,000, at the normal rate of exchange, indicating an average of $9.58 per yard. The cost is not given, for the actual operations are in the hands of a Russian company, the Lenskoie, the officials of which are not always on the best of terms with the engineers sent out from London or America. In the 1912-1913 report the cost is given as 29s 7d., or $7, per cubic yard, but even that was not official. Mr. Purington estimates the present cost at 25s.8d., equivalent to $6.40 per yard. The mining is done by drifting; the figure of cost renders comment

superfluous. Indeed, the technical work done in connection with this important gold enterprise has been pitifully bad, owing largely to conflict between the London directorate and the Russian management. The Consolidated Gold Fields of South Africa holds the controlling interest in the Lena Goldfields, which in turn has a majority of the shares in the Lenskoie company. Mr. Purington estimates the reserve of gravel in October last as 1,821,000 yards averaging 22s.2d. per yard and containing £2,023,550 in gold. Part of this ground can be hydraulicked, part dredged, and the remainder drifted. He gives 180 to 200 days as the possible dredging season, but if the methods in vogue at Dawson are adopted, it will be possible to extend the period of profitable activity far beyond this expectation. Incidentally, an interesting competition has arisen between the Poutiloff works, at Petrograd, and American manufacturers. The former is asking a price of $500,000 as against an American quotation of $425,000 for a dredge complete. It might be supposed that the domestic foundry would have much the advantage in bidding for the order, but it is a fact that the freight from Petrograd to Irkutsk is more than it is from Ohio or California to Irkutsk, the distributing point for the Lena region. The scarcity of manganese-steel may compel the use of chrome-steel in the manufacture of the buckets, using manganese-steel for the lips only.

Flotation Litigation

We referred to this subject in our issues of December 18 and January 29. Since then we have learned that the decision in the Hyde case, now before the Supreme Court by writ of certiorari, has been postponed until next October or November. The advancement of the case was due to the fact that in January three out of the nine justices of the Supreme Court were absent from the bench by reason of illness or other causes, thus leaving only six, the smallest number that holds court. One of these six was the former Attorney-General, Mr. James C. McReynolds. It so happened that several Government cases were next upon the calendar at this time, and as Justice McReynolds could not sit as a member of the Court while the cases in which he had been attorney were being heard, it became necessary to pass all of them. This advanced the hearing of the Hyde case by about two months in the most unexpected manner. Inasmuch as both parties in that litigation found it necessary to have demonstrations performed in Court, in illustration of their arguments, it became impossible to present the case on two or three days notice. Therefore, by mutual consent of counsel representing Minerals Separation and Mr. James M. Hyde, the case was set over until the October term. As regards the Miami case, it is understood that Judge Bradford, of the District Court at Wilmington, is a painstaking man and is going through the voluminous testimony with great care, in the intervals of hearing current cases. Hence the delay. The decision may be announced any day.

Metal Prices

No apology is required for referring again to this subject, for it is one that concerns most of our readers. Discrepancies in the quotations for metals, especially copper and zinc, have caused irritation and created suspicion among those who are engaging in the mining and selling of them. In particular, we have received letters commenting upon the discordance between the official prices published by the New York Metal Exchange and those quoted in the technical press—for example, in our own columns. On careful enquiry we find that practically no metal is sold on the so-called Metal Exchange in New York, the quotations issued being largely fictitious. At rare intervals a sale is recorded as having been made on the floor of this 'exchange,' but when it happens the assumption is that the transaction is performed for some sinister purpose, as when spelter was offered by a broker, not regularly engaged in the trade, for the alleged purpose of breaking the price then prevailing—a price considered excessive in certain quarters. It is a fact that this broker was deputized to make the offering at a price lower than the outside market. Again, spelter has been sold on this so-called exchange in small lots and at low prices for the alleged purpose of obtaining a quotation that could be telegraphed to the West with a view to influencing ore-prices. Only the other day, April 5, a dealer in tin made a bid of 55c. for spot tin, receiving no acceptance, and later in the day he offered to sell at 53; the inference being, of course, that the high bid was made merely to boost the price. As regards copper, only the so-called 'standard' variety is sold on the Exchange, on those rare occasions when there is a sale. This material is of no value to the consumer of refined copper. As far as we can learn, this 'exchange' serves some purpose in the collection and distribution of sundry statistics; it is a receiving and distributing point for the daily cablegrams from London; and when united action is demanded, it serves to bring the members of the trade together and furnishes a medium for the expression of their policy. Thus the habitation and the name may be useful on occasion. This happened recently when protests were lodged with the British authorities by the tin committee of the Metal Exchange, thereby securing a modification of the drastic regulations governing dealings in tin. Years ago a good deal of real business was done on the Exchange and some of its members still cherish the hope of a revival, but it is clear that unless there is some assurance of *bona fide* prices, it were better to give the thing a first-class funeral. As now conducted, it is a sham and a snare, as is evident from the confusion it has created among mine-operators. A dealer rises and asks "What shall we make copper today," to which another so-called broker replies "I bid 26," and a third "I ask 28," whereupon the average is called the 'market.' Even this hollow mockery is enacted irregularly. The Official Daily Market Report of the New York Metal Exchange—the name is long enough to be pretentious—is a publication supposed to give the quo-

tations. We have before us the statement for the week March 28 to April 6 and note that it is an elaborate blank despite the active dealings in these metals in progress elsewhere during that period. In short, the Metal Exchange is a fake and the time has come to recognize it as such.

The daily press and many financial papers are not reliable sources of information if precise figures are required in regard to the business done. It may be enough for the general public to know that copper is at the 26c. or the 28c. level, but the actual buyer or seller deals in fractions of a cent. Furthermore, a 'pegged' price is often fixed tacitly and may be quoted long after the market has sagged. Some of the prices quoted in the daily press represent what consumers are paying for metal delivered at their own plants, while others quote for metal at the refinery dock. This corresponds to a spread of ¼ cent per pound in normal times, but now that freight is so congested around New York the difference is likely to be increased considerably. In regard to 'spot' copper, either Lake or electrolytic, it should be known that this product has been so scarce of late as to be designated a specialty in the trade. Consumers do not buy from hand to mouth; they must make their purchases sufficiently ahead to ensure the continuation of their operations, so that it is with 'futures,' near or otherwise, that the actual market is concerned in these days. Our New York correspondent has reported repeatedly that immediate shipments command premiums and that these premiums are paid by few important consumers. The business recorded recently has been mostly in June, July, and August deliveries. Sales have been put through in large volume at from 26.75 to 27.50c., yet all the time the daily press and some Wall Street papers have proclaimed 28.50 as the price of copper. It is, and it is not. The fact is that the daily press does not keep in close touch with the market; in this, as in so many other matters, it is crudely careless about accuracy. Further, it may be assumed, for the purpose of business, not philosophy, that if a newspaper or other periodical has a certain clientele it will lean toward the interest of that clientele. In the same way a broker that speculates in metals is an unreliable arbiter of prices, and metal-selling agencies in the East have to make strategic movements that disregard the welfare of individual producers of copper or zinc in the West. The subject is complicated by the interplay of a number of forces, some of them sinister. Since the beginning of the War there have been many disclosures, at Melbourne, London, and New York, indicating that the owners and operators of mines are sitting in a game not conducted according to the rules of clean business, the essence of which is that it is mutually profitable. Again we suggest that one of our professional organizations, the American Institute of Mining Engineers or the Mining and Metallurgical Society of America, should appoint a committee of investigation to enquire into the whole question of metal buying and selling. No subject is of more immediate importance to the mining industry.

Mining Engineers and War

Directors of British mining companies have been requested by the Institution of Mining and Metallurgy to keep in mind the engineers who are serving in the War, so that they may be afforded every facility of return to their former employment when peace is assured. Seven hundred members of the Institution are on active service with the British army and already 30 have given their lives while doing their duty. Of course, mining engineers and metallurgists are serving their country with equal devotion under other flags, but we may be pardoned for taking a special interest in those whom so many of us in the West have known in this and other countries. We are proud of them, for they have made a splendid record, especially in that most dangerous form of warfare: tunneling and laying mines. To them the old meaning of mining has been brought back literally. Among those to distinguish themselves have been Ralph Stokes, formerly at Johannesburg and later with the Canadian Exploration Company in New York; enlisting at the beginning of the War, he is now captain and has received the Military Cross. W. S. Holloway, formerly manager of the Gwendoline mine in Korea, serving as lieutenant in the Royal Engineers, has received the same decoration "for conspicuous gallantry." This cross of honor has also been awarded on proof of similar courage and intelligence to Herbert Eyden, H. C. B. Hickling, Arthur Hibbert, Hugh R. Kerr, and H. R. Ruggles-Brise, all of whom are lieutenants, and to Laurence C. Hill, Lionel E. Hill, Stuart G. Love, R. S. Mackilligin, and C. M. Euan Smith, all captains. Also to Major G. W. Laws, who has received, in addition, the Croix de Guerre from the French. J. Norton Griffiths, well known in South Africa, has been awarded the D. S. O. and is a major. Of all of these men the profession may well be proud. Among the mining engineers from this side of the Atlantic summoned by the call of duty to military service are the following: F. K. Borrow and Harold Rickard, both formerly in Colorado; Fred. B. Reece and J. H. Fennell, recently in Arizona; Morton Webber of New York; Peter N. Nissen, who invented the stamp; Lionel Lindsay and Gelasio Caetani, from San Francisco. Messrs. Lindsay and Reece are graduates of the University of California. Most of these men are holding commissions in the engineering corps or in the field artillery, for both of which services their previous experience helped them. Mr. Caetani is with the engineers of the Italian army; the others are with the British forces in the field. Mr. Webber has seen service successively in Flanders, where he was wounded, at Gallipoli, and in Bulgaria; he has been invalided recently. Whether the mining profession in America may have a similar call in the near future, we do not know; but it is certain that the members of it will be as quick to respond. Meanwhile an effort is being made to organize the engineering societies for effective co-operation with the Army and Navy. That is one of the best moves toward preparedness.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Flotation Principles

The Editor:

Sir—I have noted with great interest Mr. Durell's reply, in your issue of February 19, to my discussion[1] of his previous article.[2] It seems to me that in this reply Mr. Durell has discussed the subject in a manner entirely different from that of the article criticized. It also seems to me that he has related his experiences in Australia in a particularly valuable way and I am certain that the metallurgical profession has read them with great interest. Mr. Durell has also taken us more into his confidence as to why he believes that 'nascent' and 'occluded' gases are the necessary adjuncts of flotation, and has given us references for many of the facts that he has used as a basis for his theory. A parallel paper on much the same subject was sent to the Colorado School of Mines *Magazine* and published by it in the February 1916 number, and later copied in *Metallurgical and Chemical Engineering*, XIV, 50 (1916). Between these two papers of Mr. Durell's, I have been able to obtain a much better understanding of his theory, and this communication is intended to supplement my former discussion.

One of the two papers by Mr. Durell ends with the statement that he has shown "that all processes and kinds of flotation can be satisfactorily explained by gas occlusion and that the bubbles for froth formation are from nascent gas." It seems to me that Mr. Durell might well have added the qualifying phrase, "provided that all of the assumed factors prove to be true." I believe that a rigid analysis of Mr. Durell's logic will show that most of his theory, in spite of all the references given, is still based on some assumption that few, if any, physicists or physical chemists will be willing to accept.

Summing up Mr. Durell's argument, as I now understand it, we have the following: (1) Certain former experiments of Mickle's lead Durell to believe that 'nascent' gases (gas that has been in solution and is on the point of being liberated as free bubbles of gas by any means whatever) are the only forms of gas effective in flotation. Bubbles of gas already existing in the liquid will not attach themselves to mineral particles and cannot be made to do so. (2) This nascent gas can only form into bubbles when there are nuclei present in the shape of solid particles—in this case particles of ore —and on these nuclei the bubbles of gas grow. (3) Mineral particles containing a large amount of occluded gas are the ones on which the nascent gas tends to collect to the greatest extent, and these are the metallic minerals. (4) The effect of electrolytes is to expel some of the 'occluded' gas from the metallic minerals, and nearly all of the gas in the gangue minerals, the surfaces of the mineral particles acting as septa so that the osmotic pressure of the dissolved salts expels or replaces some of the occluded gas, allowing cleaner flotation. (5) The effect of flotation-oils is to lend stability to the froth of mineral-laden bubbles which form on the surface of the pulp, that is, it causes stronger bubbles by adding the surface tension of the immiscible portion of the oil to that of the water, and, as good frothing oils do not evaporate readily, by rendering the film of water over the bubble less easily evaporated. Further, the oil decreases the adhesive force of the water for metallic mineral particles by forming oil-films around these particles, and the network of oiled particles on the surface of a bubble tends to increase its stability.

Taking up these points in order, let us see how many of them have a firm basis in fact. The first statement is that 'nascent' gas is all-important and that a gas bubble which is already formed cannot be attached to a particle. In this connection it may be of interest to note that in the suit of Minerals Separation against Miami Copper Co. both sides introduced experimental evidence in the Court in which a bubble of air, held on the end of a glass rod, was to pick up mineral particles from the bottom of a glass vessel under various conditions. By merely putting the bubble in contact with the mineral particle no difficulty was experienced in lifting it. The Minerals Separation experts produced moving pictures of this experiment and experts for the Miami Copper Co. actually carried on the experiments before the Judge, who was provided with a large reading-glass. No one has hitherto questioned the reality of this fact.

The second statement is that 'nascent' gas will only form into bubbles when it has nuclei consisting of solid or other particles on which to form. I believe that this fact is fairly well established by physicists, and hence I agree with Mr. Durell.

The third statement is that mineral particles containing a large amount of occluded gas are the ones upon which the nascent gas tends to collect to the greatest extent and that the metallic minerals 'occlude' more gas than do the gangue minerals. The fact that even original igneous rocks from the depths of the earth hold

[1] "Why do Minerals Float?" by O. C. Ralston, M. & S. P., October 23, 1915.

[2] "Why is Flotation?" by C. T. Durell, M. & S. P., September 18, 1915.

large amounts of truly occluded gas is not denied, although Mr. Durell has not mentioned it. But I do not believe that Mickle's experiments give us any data on the amounts of gases 'occluded' by gangue-minerals as compared with metallic minerals. Mr. Durell quotes the experiments of Swinburne and Rudorf as demonstrating the presence of gaseous envelopes on the surfaces of dried mineral particles. This is a fact that no one wants to deny, but it is probable that this envelope of tightly held gas on the surfaces of particles, mentioned alike by Mickle and by Swinburne and Rudorf, has often been confused with the truly occluded gas that is within the substance of the particles. This gas envelope is *adsorbed* on the surfaces of particles and held there with great tenacity so that it is doubtless actually compressed by the molecular forces of attraction—variously named adhesion or what not. I gave references to this fact in my former discussion. This gas envelope, held by a submerged particle, might play an important rôle in the attachment of 'nascent' gas, but as far as I know there is no experimental evidence to prove that it does, and Mr. Durell presents none. He says that Hebron, the associate of Carrie Everson, used a microscope in discovering that the desirable minerals were more porous and presented greater surface than the gangue-minerals, but I know of no other observers who are willing to go on record with such a statement.

James A. Block described to me an experiment that he tried in order to test this third point of Durell's, and asked me to check his work. Through the kindness of E. P. Barrett, of this laboratory, this has been done. Using a glass-rod bubble-holder, such as was employed in the Minerals Separation-Miami case, portions of powdered galena and of quartz were tested for flotation in boiled distilled water. The particles of mineral were introduced into the distilled water and then left on the hot plate to boil for several hours. Thereby all dissolved gases in the water were removed, and presumably all of the gaseous envelopes on the mineral particles, and all occluded gas within reach of the surfaces of the particles. Under these conditions, according to Mr. Durell, even nascent gas could not attach itself to the particles, and the bubble in the bubble-holder never should do so. However, the galena and quartz particles were both lifted with comparative ease, in hot water, just removed from the hot plate, and before any gas had time to dissolve in the water or get at the mineral particles. The addition of a small amount of sulphuric acid to the water caused no change in the action of the galena, but the quartz would no longer lift. The experiment was repeated after further boiling of the same water with the same particles, more distilled water being poured in from a large beaker that was boiling at the same time on the same hot plate. The galena in distilled water was tested at intervals for two days and always came up. At that time a small amount of suspended white material from interaction of galena with the water was visible, although the flotation of the galena did not seem to be interfered with. At this point the experiment was discontinued.

No claim is made that this experiment of Mr. Block absolutely refutes Mr. Durell's theory, but I do insist that it casts a very serious doubt upon it.

The fourth step in Mr. Durell's argument, involving osmosis with the surface of the mineral particle acting as an osmotic septum, so that ions of an electrolyte diffuse into the mineral particle while "those of the gas leave," rests, I believe, on assumptions. In fact, I think that the whole of this fourth argument will find little support from the rank and file of physical chemists.

The fifth part of the argument, which deals with the effect of oils in *increasing* the surface tension of the water by adding to it the tension of the oil film, I shall leave to Messrs. Rickard, Coghill, and others who have been recently writing on that subject. I believe that their recent papers contain data sufficient to refute many of the claims which Mr. Durell has made. He has had to explain the action of the oil in order to make the remainder of his theory plausible. There are many people who will agree that one of the main functions of the oil is to cause frothing, although they have very definite data to prove that the surface tension is greatly *decreased* under the conditions whereby good flotation is obtained. However, many more definite experimental data on these points are necessary before anyone can state what is the true function of oil in froth flotation.

From what has gone before, it can be seen that Mr. Durell's main arguments have an insecure foundation and that while he has many interesting references on minor points and has evidently reviewed carefully all of the experimental work that is reported, the main points of his theory rest largely on conjecture.

He has stated that both of my hypotheses as to why minerals float involve the use of oil, and that therefore both hypotheses are of no value, as oil is not an essential element of flotation. Without drawing out this argument to burdensome length, let us examine it. With negatively-charged gangue-minerals, positively-charged metallic minerals and negatively-charged air-bubbles, we have all the electric conditions favoring attachment of air bubbles to the metallic minerals and a good reason for their avoiding the gangue. By the use of a flotation-oil we can modify the surface tension and other properties of the water so that it froths better. Let me also state that we have actually seen, by using a microscope, such charged particles move under the influence of an artificial electric field, and know that they have electric charges. I feel that definite experimental evidence of this kind is of much more value than conjecture.

I find that I have been more or less credited with being the originator of the 'electrical theory.' This is a mistake. So far as I know, the first public mention of electric effects, as I stated in my first discussion of Durell's theory, was made by George Riter, and later by J. M. Callow. Both of these gentlemen had spoken to me privately on the subject before their public utterances and I had told both of them that while electric charges were common to all colloids, I did not feel that this was the only property of the particles in question to be considered. I stated so in my former paper and now

wish to reiterate the belief that a comprehensive theory of flotation will have to take many different physical properties of small particles into consideration, among which are their electric charges and the interfacial tensions of the phases involved. In other words, such a theory (which has never yet been enunciated) might be called a 'colloidal' theory, if we remember that many of the special physical properties of the true colloids are important enough to be in evidence even in the coarse suspensions with which we have to deal occasionally in flotation.

Salt Lake City, March 14. OLIVER C. RALSTON.

Platinum at the Boss Mine

The Editor:

Sir—The recent article by Mr. F. A. Crampton on 'Platinum at the Boss Mine, Goodsprings, Nevada,' gives much valuable information, especially with reference to the details of the distribution of certain of the metals throughout the deposit. It is to be regretted, however, that Mr. Crampton has not given us from his intimate knowledge of the Boss deposit some data on the relative distribution of the palladium and platinum. Of these two metals palladium is far the more soluble, approaching silver in this respect. Now the most remarkable geologic feature of the Boss deposit is the great mobility that the platinum appears to have had in oxidizing solutions, and to this unexpected property the extreme localization and enrichment of the precious metals in the Boss deposit is probably due. When the extraordinary resistance of metallic platinum to most chemical reagents is considered this ease of solubility in the zone of oxidation is truly astonishing. This leads to the supposition that in the primary ore, which remains as yet unknown because of the insufficient development of the mine, the platinum is present as a chemical compound that is easily susceptible to oxidation, and that the platinum under the conditions of oxidation, being then in the nascent state, goes readily into solution. An analogy for this supposition is afforded by tin-bearing ore deposits. Under most conditions tin ores are not enriched by secondary processes, because cassiterite is strongly resistant to the natural solvents occurring in the zone of oxidation, but if the tin is present in the primary ore as stannite or other stanniferous sulphide, secondary concentration readily takes place. Until, however, deeper exploration discloses the primary or 'hypogene' ore of the Boss mine, which, as I have elsewhere shown, will be found to contain the sulphides of copper, lead, iron, and bismuth, the problems concerning the genesis of the oxidized ores cannot be fully solved.

One of the closing statements in Mr. Crampton's article is not strictly accurate. The occurrence of platinum ore at Broken Hill, Australia, is not similar to that at the Boss mine. The Broken Hill deposits have recently been described by Douglas Mawson.* The platinum occurs principally in copper and nickel-bearing gossans of small and irregular dimensions. All the occurrences are closely connected with magnesian igneous rocks, and hypersthene gabbro (norite) is associated with them. It is believed that they represent sulphide segregations from basic intrusions, and that accordingly they are analogous to the platinum-bearing ore in the norite at Sudbury, Canada. The deposit at the Boss mine therefore still remains unique.

Washington, D. C., April 8. ADOLPH KNOPF.

Oxidation

The Editor:

Sir—In referring to the chemical change which gives rise to the formation of oxides, which of the two following terms is the correct one: 'oxidation' or 'oxidization'?

Charles Janin, in 'Mining Engineers' Examination and Report Book,' on page 9, seventh line, speaks of "depth of oxidization." This quotation caused an argument between two men. One man contended that there was no such word as 'oxidization' in the English language, the other man contended that while the word was not correct its use was permissible owing to general usage. Hence this appeal to you.

Seattle, April 17. JOHN T. TOWERS.

[Oxidation is correct. 'Oxidization' is to oxidation what 'preventative' is to preventive.—EDITOR.]

Mine Accident Insurance

The Editor:

Sir—Our attention has been drawn to an editorial on the above subject which appeared in your issue of April 1, and to a reply from Mr. Will J. French of the California State Industrial Accident Commission published in your issue of April 15. This is a matter of grave importance to the members of our association and we are glad that Mr. French has replied to your editorial, because much can be gained by public discussion and a full and fair elucidation of the facts.

The common grounds upon which we can meet Mr. French and the other members of the Commission are:

1. That all reasonable steps for the prevention of mine accidents should be taken by the operators.

2. That the insurance, however carried, should be an absolute and complete protection for our employees; and

3. That we should be allowed to obtain that insurance at as low a rate as is compatible with complete security.

We are bound to give the California State Industrial Accident Commission and the State Insurance Commissioner credit for full honesty of purpose in handling this question, even though we express doubt as to whether they always pursue the proper course, and that the public may know the facts we will ask them if the following statements are not true?

Either Mr. Pillsbury of the Commission or Mr. Fel-

lows, its manager of the State Compensation Insurance Fund, stated in an open meeting in the fall of 1914 that the Commission had no experience on which to base a mining rate and that they felt they should play safe and therefore made the rate 7.86%.

The Commission was then informed that the State of Nevada had been insuring mining risks for more than a year at an average of about 2.2%, and the Commission immediately telegraphed the Nevada Industrial Commission for information on this subject.

The secretary of the Nevada Industrial Commission came from Carson, and after a conference with him, the State rate on mining risks was reduced to 5% for underground men and 3.75% for surface men. Is it not a fact that neither the State nor any insurance carrier ever wrote any considerable amount of mining insurance at so high a rate as 7.86%, and that ever since the reduction made on January 1, 1915, the mining risks carried by the State Compensation Insurance Fund have represented an almost negligible percentage of the total mining risk carried?

We challenge the statement that "the State Compensation Insurance Fund has the only reliable statistical data on the subject." Admittedly, in the fall of 1914 it had none, while the corporation which has written the risks of a large number of our members had been in the same or similar line of business, making a specialty of mining risks, for many years. If it be true that during the past year, the total Workmen's Compensation insurance business of this corporation has resulted in a loss, it is by no means certain that this loss is due to the mining department, in which it has had its longest experience, and still less certain that the mining department of its California business has resulted in loss. On the contrary, it seems to us quite probable that losses incident to unusual catastrophes in Montana, where premium rates lower than those of California prevail, may have had something to do with the temporary loss. In this connection this Association is now collecting data on the experience of some of its members who carry their own insurance. These members have a total of over 2000 employees, and while the information is not yet sufficiently complete for publication, its compilation has advanced sufficiently far to enable us to say that when the figures are complete they will show that the total cost to these companies for carrying their own insurance, including amounts set aside for the payment of deferred and contingent losses will not exceed 2.3%.

The reference in Mr French's letter to the Commonwealth Bonding & Casualty Insurance Company of Texas seems to us hardly fair. This concern may have written some mining business in California; but, if so, it is not known to the members of this association, the volume of whose pay-rolls equals at least 90% of the total mining pay-roll of the State. On the contrary, that concern, which had been licensed to do business by the State Insurance Commissioner, was made the subject of an independent investigation by our Association, and its policies declined.

That your readers may know how serious this matter is for the members of our Association, we might add that we estimate that if the employees of all members were insured, the difference between the rate fixed by the State Insurance Commissioner and that which many of our members are now paying would amount to at least $120,000 per year. In conclusion, we repeat that, while we are glad to co-operate with the Industrial Accident Commission in minimizing the chances for accident, and desire that those of our employees who may be injured be assured of receiving all the compensation to which they are entitled under the law, we do not feel that we should, without vigorous protest, pay $120,000 per year to assist the State of California in its experiment with the insurance business.

ALBERT BURCH, President.
ROBT. J. KERR, Secretary-Treasurer,
California Metal Producers Association.

San Francisco, April 18.

McDougall Roaster

The Editor:

Sir—I notice in your issue of April 15 a sketch of the McDougall arm and rabble, to which you refer to in the text as the Kelly arm. This arm is covered by the Thomson-Kelly patent No. 940,488. Please note that the patent is the Thomson-Kelly, not the Kelly, nor the Kelly-Thomson as Hoffman has it.

H. N. THOMSON.

Clarkdale, Arizona, April 17.

Antimony-Gold Ore

In our issue of April 15, on page 542, a typographical error was made by transposing and repeating the last equation. The first equation, illustrating the solution of antimony sulphide in caustic soda, should have been

$$Sb_2S_3 + 6NaHO = Na_3SbS_3 + Na_3SbO_3 + 3H_2O$$

THE EXPANSION of American industry in foreign countries has been hindered by inadequate methods of exchange. The National City Bank of New York is leading the way in facilitating American participation in the development of Latin America and the Orient. Branches have already been established by that enterprising bank in the following Latin American cities: Buenos Aires, Montevideo, Havana, Rio de Janeiro, Sao Paulo, and Santos the latter three being in Brazil. The same house, by securing control of the International Banking Corporation, now has connections at Panama, Colon, Manila, Cebu, Bombay, Calcutta, Singapore, Yokohama, Kobe, Tientsin, Peking, Hong Kong, Canton, Shanghai, and Hankow. A Russian division has been organized with agencies in London and Petrograd.

AVERAGE price received by Michigan copper mines for their product in 1915 was 18.4c. per pound. The highest was 19.83c. paid to the Franklin.

Mining in Northern Arizona

By Charles F. Willis

MINING in the northern half of Arizona has been highly stimulated of late. The name of Oatman has echoed far and wide, but the Oatman boom is bound to be rivaled by the excitement at Jerome. Jerome is the hub of the copper-mining activity of the northern half of the State. While it has been for years a one-mine camp, it is now out of that classification.

One of the most spectacular happenings in Arizona has been the record of the United Verde Extension Mining Co., known as the Little Daisy. This mine is not two years old, but, within its short life, its stock has risen from 30 cents per share to $27. It is claimed that it will be earning $4 per share within a few months. While this mine is shipping but 200 tons per day, the ore is practically all from development. During the month of March, 5920 tons of ore was shipped. The company makes a remarkable classification; first-class ore is 30% copper, second-class is 15%. The output in March was 2,000,000 lb. of copper. Practically all the work is centred on the 1400-ft. level, developing a single orebody, which is now 120 by 200 ft., with neither wall reached. A raise has been put up for 65 ft. and the upper limit not found, yet this wonderful orebody averages better than 20% copper.

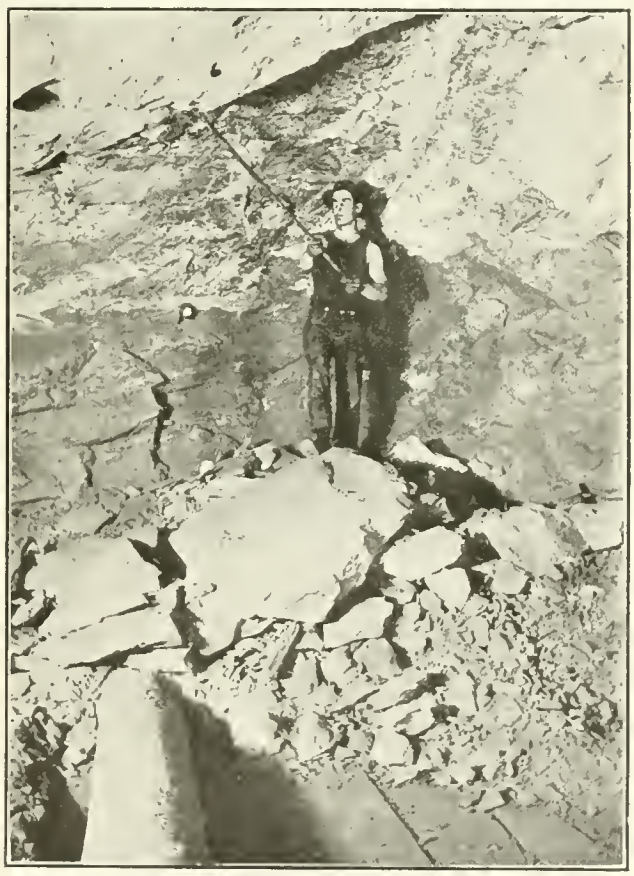
The excitement attending the success of the Verde Extension is shown by the rapid financing of the Green Monster Mining Co. in the same district. The Green Monster adjoins the Copper Chief, which in turn adjoins the Verde Extension. The directors offered 600,000 shares of stock to the public, allotment being made to the principal towns in Arizona. The stock was to be sold in lots of not less than 1000 shares; within three days the stock was several times over-subscribed.

Jerome, however, is not the only part of Yavapai county where there is mining activity. The Bradshaw mountains are to have an adit similar to the Roosevelt tunnel at Cripple Creek. An adit 12,000 ft. long at a maximum depth of 1800 ft. is planned for drainage and transportation. Notable among the mines that will be tapped at depth are the War Eagle, Gladiator, Nelson, Fairview, Spring Green, and Lincoln. None has produced less than $500,000 during years of adverse conditions.

The cinnabar mines of Copper Basin are attracting attention, owing to the high price for quicksilver. It is reported that the quicksilver belt of Copper Basin is 1½ miles long and 300 to 600 ft. wide, with an average of nearly 2% mercury. This district has the advantage of accessibility, being but seven miles from the Santa Fe, Prescott & Phoenix railroad.

The Consolidated Arizona Smelting Co. plans to increase the capacity of its flotation plant at Humboldt from 250 to 600 tons per day. The Blue Bell mine is shipping to the Humboldt smelter six carloads of ore daily. The De Soto mine, also owned by the Consolidated Arizona, is shipping four carloads daily, this mine being limited in output by the capacity of its aerial tram for delivering ore to the railroad.

While the 'boom' period has passed in Mohave county, the work of developing the Oatman, Secret Pass, Union



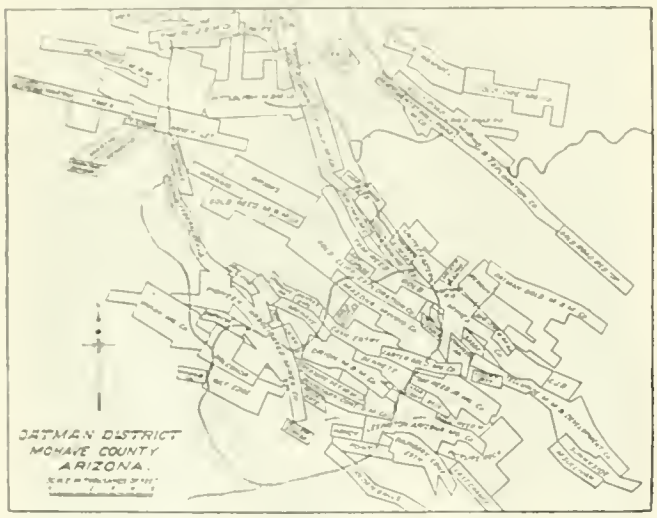
BARRING-DOWN IN A CUT-AND-FILL STOPE.

Pass, Black Range, Golconda, and other districts proceeds steadily. The reported strike in the United Western at Oatman spurred the 160 companies operating in that district to greater effort. Oatman has the distinction of having a mining company owned and operated by women. The Murdock Extension Co., promoted by a group of Los Angeles women, has an option on five claims. The same women are prominent in the political life of Los Angeles; Miss Musa Rollings, secretary of the Murdock Extension, is also secretary of the Women's Democratic League of Los Angeles county.

A large hoisting plant is being installed by the United Western. While this mine has found but 6 ft. of brecciated quartz, quartz is usually an indication of the top

of a body of coal ore. The United Eastern Co. continues steady development underground, constantly adding to its reserves. A new three-compartment shaft, 700 ft. from the old shaft, is being sunk, and preparations for the construction of a 100-ton mill are being rushed. J. A. Burgess has just been appointed resident superintendent, resigning the management of the Nevada Wonder mine. The Tom Reed and the Gold Road still continue a steady production of about $100,000 per month each. Development at nearly all the Oatman mines is conducted on similar lines; a hoist and a compressor are installed and a shaft sunk to 500 ft. before lateral work is started, it being assumed that good ore will not be found near grass-roots.

Northern Yuma county is to the fore. In the vicinity of Parker several prospects are getting under headway. The Empire-Arizona company is making shipment by auto-truck to Parker, and new orebodies are reported.



A road is planned to Parker, to reduce the distance from the mine to the railroad by nine miles. The Billy Mack is producing steadily. It is rumored that strong financial interests will open up this old-time producer on a large scale. The Zerolite-Mammon, which was recently purchased by Nevada people, is preparing to ship. W. B. Andrews, the manager, is at the mine ready to start development. The Swansea-Planet region is humming with life. The Swansea lease, on the Clara Consolidated mine, held by the Thomas estate, made a profit of $22,000 in March, and probably will exceed this in April. Three carloads per day are going out of Swansea and the ore is averaging slightly over 4% copper. A new orebody, 36 ft. wide, has been opened, averaging over 5% copper. The Planet is shipping 40 tons per day to Midway, a station on the Swansea railroad. The ore is running 18% copper, and it is a bonanza for the owners. Motor-trucks are employed for transporting the ore. The manganese claims in the Planet range, eight miles from the Swansea railroad, have been sold to a syndicate. Bids are being asked for the transport of ore to the railroad, a haul of eight miles. It is planned to ship 200 tons daily. The Lowell mine, near the Planet, has been sold to Salt Lake City men, who will begin operations at once.

On account of the shortage of cars, caused by the requisition of the Government along the Mexican border, a large stock of copper accumulated recently at the International smelter and the Old Dominion. Finally, a single large shipment was made containing 49 cars of copper, over 2000 tons, valued at $1,063,870. This is probably the largest shipment at one time from any district in the State.

A plant for the production of metallic molybdenum has been erected at Tucson. Although Arizona produces most of the molybdenum of the United States, there are many deposits to which little attention is paid, owing to the high shipping charges to distant smelters.

Every smelter in the State is working to capacity, and has been receiving more ore than it could handle. The result is shown in increased smelter charges, which will tend to eliminate low-grade ores. Some dissatisfaction is expressed at the new schedules, but it is realized that conditions are abnormal.

Concentration of Zinc at Butte

The following notes are from the report of the Butte & Superior Copper Co. for 1915:

The flotation department was re-built to improve its efficiency and increase its capacity. The greater tonnage treated made it necessary to add to the fine-grinding and slime-settling apparatus. These improvements resulted in the plant treating 60% more than in 1914, with better recovery and lower cost. There was 522,300 tons treated (the last quarter of the year at the rate of 600,000 tons per annum), with 92.21% extraction (95.07% in last quarter), an increase of 3.5%, at a cost of $1.75 per ton, a reduction of 37c. per ton. Details are as follows:

Average assay of ore: 0.01409 oz. gold, 7.6299 oz. silver, 0.2121% copper, 1.2127% lead, and 17.0211% zinc. Zinc concentrate (152,897 tons) assayed 0.0403 oz. gold, 22.14 oz. silver, 0.573% copper, 2.448% lead, and 53.616% zinc.

Zinc concentrate contained 6164 oz. gold, 3,385,164 oz. silver, 1,751,545 lb. copper, 7,485,489 lb. lead, and 163,956,791 lb. zinc.

Lead concentrate (5274 tons) assayed 0.542 oz. gold, 33.792 oz. silver, 0.386% copper, 37.815% lead, and 13.52% zinc.

Lead concentrate contained 286 oz. gold, 178,218 oz. silver, 40,665 lb. copper, 3,988,679 lb. lead, and 1,426,130 lb. zinc.

The gross value of metals was $13,244,133, of which $9,074,152 was profit, and $4,908,115 was distributed in dividends.

Production of primary spelter in the United States in 1915 was 489,519 tons, an increase of 39%. The value, $121,401,000, was an advance of 237%, while the domestic consumption was greater by 22%, according to the U. S. Geological Survey. Further notes will be found in our New York metal letter.

A PLACER-DRILL. ANOTHER DRILL, IN OPERATION.

Prospecting Before Dredging on Seward Peninsula, Alaska

By Corey C. Brayton

INTRODUCTION. Seward peninsula, just below the Arctic circle, is the most western land of the American continent. Nome, I believe, is the only mining town that is also a seaport, but without harbor or docks. It stands on a sandy beach on the edge of the coastal plain, which extends four miles to the foot-hills. Vessels anchor a mile off shore and handle cargo and passengers by lighters and cable-way. The Government could, at a cost of a few thousand dollars, make Snake river an excellent harbor for small craft such as coastwise gasoline-boats. As yet, the Government has done nothing to help shipping at Nome; it has done little to aid Alaska (as compared with Canadian treatment of the Yukon) except the present railroad construction and the excellent work of the Geological Survey such as conducted under Alfred H. Brooks. Geological reports have been issued promptly and have been used to a much larger extent than in the States.

The climate of the peninsula during the four summer months is not unlike the winter climate of San Francisco. The temperature begins to drop in September, and by the first of October hydraulic and pick-and-shovel operations cease. The 'freeze-up' comes in late October and puts an end to dredging.

PROSPECTING. The churn-drill as a machine for testing gravel deposits was first used in this region during 1902 by A. A. Allan for J. W. Kelly on Dexter creek. This was a regular oil-well rig with a short tower. It was used in frozen gravel to a depth of 200 ft. Following oil-well practice, the hole was started large, 10 inches, and then tapered. I am told that this method of testing for gold, at least as far as Kelly was concerned, was original. He had not heard of the Keystone drill which had been employed for similar work in California since 1898.

This Keystone drill was soon introduced and became the standard machine for testing alluvial ground. It was used alike for shallow and deep drilling, in frozen ground and in thawed. In frozen ground no casing is required even though the hole may be 200 ft. deep or more. This soon became the accepted method for tracing the gold concentrate in old channels and beaches, and for testing dredging ground. For the former purpose it was more of a qualitative than a quantitative test. Ordinarily no attempt was made to test a 'pay-streak' thoroughly with the drill. If one or several holes showed 'pay,' a shaft was sunk and the 'streak' was tested with drifts. It was not the general practice in such drilling to wash up the entire content of the hole, but only the parts that looked promising. This is especially the case with the greater part of the drilling in the beach area between Nome and the foot-hills.

In testing dredging ground the method was standard drilling and pumping. The greater part of such ground is shallow, usually less than 15 ft. An average depth would be 10 ft. A considerable area as shallow as 6 ft. has been dredged. Usually there is too much water to dig pits or sink shafts—an economical method of testing where the ground is shallow. The results obtained by the Keystone in this class of work were satisfactory, but the machine was expensive, and fuel and repairs costly. Recently gas-engines have given as good satisfaction as steam at a much lower cost for fuel. While the Keystone gave satisfactory results it was not a machine that the average claim-owner, and every man in Alaska owns from one to a dozen claims, could use for

testing his ground. It was expensive even for those who could afford it.

Lack of roads and the scattering of ownership among a large number of men without either the time or the money for testing the shallow ground created a demand for a cheaper method. It is true that some of the equipment evolved is crude, but it honestly applied the results are not unsatisfactory. The start of development was something as follows: Some miner, who had seen a drill work, wanted to test his own shallow ground. He drove a 2-in. pipe with a hammer to bedrock, pulled the pipe, and found he had some bedrock in the end and a core of gravel above. He probably told his friends, who also tried it. Driving with a hammer is slow and batters the pipe badly, so someone rigged up a heavier weight. Next came a 3-in. pipe and then a 4-in., and with this came the tripod and rope for handling the heavy driving-weight. This is the simplest equipment now employed, though the 2-in. pipe is still used at times by the miner for rough work. Next came the rig with a better application of hand-power, and finally the light gasoline rig. Different types of hand and power rigs have been used, but it will suffice to discuss only a few.

A common tripod type of hand-rig is constructed and operated as follows: Three two-by-fours or poles are fastened together at one end by a bolt or rope lashing from which is hung a single sheave. The rope attached to the driving-weight passes over the sheave and two or three men raise the weight by direct pull. The weight is usually a round bar, 2½ or 2¾ in. diam., with a welded driving-head or bolted clamps, the total weighing about 100 lb. The pipe is driven to bedrock, pulled and the core removed. There is nothing new in this rig; it is in common use for many purposes.

The rigs affording a better application of power are not numerous, and not all agree that this type of machine is more satisfactory. In general, the rig is a tripod or frame equipped with a windlass for controlling the length of rope, and a walking-beam. An attempt was made to secure a more efficient application of manpower, and I believe it is an improvement over the straight-pull rig. The operation is the same as above, but the driving-weight is heavier.

Finally came the light-weight power-rig. The first attempts along this line were clumsy affairs. In 1911, Julius Saupe, of Kimball & Saupe designed the first satisfactory rig of this type. It was soon followed by others, till now the light power-rig is generally accepted as the machine for testing ground up to 15 or 20 ft. deep. Each design has a different motion for actuating the bit, and there are other differences. The problem has been to build a light, portable, durable, and foolproof power-machine that two men can move easily over the ground to be tested. The biggest problem has been to keep down the weight and still have a durable machine of good capacity. No attempt has been made to equip with traction, as the advantages would not justify the extra weight and cost. All have a power-hoist for handling pieces of pipe and bit, and another for the sand-pump, though the latter is used only in frozen ground. The engines are of light weight, and vary from 2 to 4 hp. The bit has two squares for clamps, and ranges from 100 to 150 lb. The clamps weigh 50 lb., making a total weight of 150 to 200 lb. The length of the stroke is 24 to 36 in. at 20 to 60 per minute. The total weight of the machine is 750 to 1300 lb. Each machine has two wheels for moving, and is provided with pipe wrenches and jacks or, in one case, a power device for pulling pipe.

The light power-rig and the hand-rig make use of a new method as applied to placer ground. The universal method for testing gravel has been drilling and pumping. This method makes use of machines originally developed for drilling oil and water-wells. The first machine used for testing gravel in the United States was a Keystone operated by Newton Cleaveland for W. P. Hammon and R. H. Postlethwaite at Oroville in 1898.

The new way is a coring method, locally called pipe-driving or drilling, more frequently the latter. The same idea has been adopted in the sampling of mill-tailing, so it is not original except in its application to placer ground. It has proved highly satisfactory on Seward peninsula because the conditions there are favorable. In other deposits, such as at Oroville, it would, I believe, be an absolute failure.

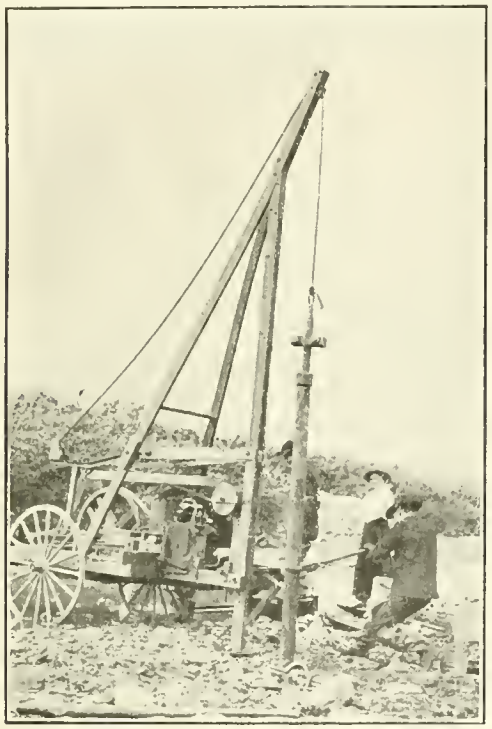
The creek and river deposits of the Seward peninsula are shallow and thawed. The wash is usually angular and, compared with other deposits, for example in California, is soft. A most expressive term applied to it by a friend of mine is 'square wash.' Some of it is inclined to be slabby. Only a small proportion exceeds 6 in. diameter. It is what may be termed 'loose.' The bedrock is either limestone, frequently metamorphosed to an almost white marble, hard but shattered or seamy, or it may be mica-schist usually decomposed for several inches. These are ideal conditions for pipe-driving or coring.

The general practice is as follows: A single length of 4-in. pipe, the length depending on the depth of gravel, is set on end and driven to bedrock. Experience enables the operator to 'feel' bedrock as soon as it is struck. The pipe is driven into bedrock for a few inches or even a foot or more, depending on the penetration of the gold. During the driving the pipe is rotated by one man with a pair of chain-tongs. The rotation keeps the pipe loose and aids materially both in driving and pulling. The pipe is pulled with a step-jack, a lever, or power puller. A 10-ft. hole can easily and quickly be pulled with a No. 2 jack. In pulling, care must be used to prevent excessive vibration and consequent loss of the bottom few inches of the core. The pipe is hoisted clear of the ground and a galvanized-iron tub is placed under it to receive the core. The most satisfactory method of removing the core is by pounding the pipe with a light hammer. A little experience will enable the entire core to be removed in approximately definite sections, for inspection, but ordinarily only the bedrock and a few inches above are tested separately. Finally the entire core goes to the rocker.

Standard or extra heavy pipe is used, the former being

more easily handled but not lasting as long. No shoe is employed and couplings are avoided by using the longest section possible. Shoes and couplings interfere seriously with both driving and pulling. The end of the pipe is kept sharp by filing, and when split or broken is cut off with a hack saw. A sharp pipe drives much more easily than a dull one. In case more than one length of pipe is necessary, a driving-ring a little heavier than a coupling is screwed on. Otherwise, either a ring is shrunk on or no ring is used.

The ideal pipe would be steel tubing, and though it costs more, it should last longer and should drive with



THE AUTHOR'S LIGHT POWER-DRILL.

REMOVING THE CORE.

minimum friction, since it has a smooth surface both outside and inside. Pipe friction is most marked with a light rig, both in driving and pulling. It is present in the same proportion with a heavy rig but is seldom noticed.

The advantages of this method are accuracy, speed, and cheapness. It is difficult to convince one who has not used this method that it is accurate. Innumerable reasons can be imagined why it should not be, but the "proof of the pudding is in the eating." The average operator or engineer would say that a small pipe will soon choke by friction and then merely displace material the same as a solid cylinder, but it does not. The core frequently shows discs from 2 to 4 in. thick cleanly cut all around, and as frequently shows equally thick cuts from the end or side of a boulder. Often these are hard rocks. Undoubtedly at times the pipe strikes a boulder and shoves it to one side, so also does a 6-in. pipe. Sometimes a hard cobble a little larger than the pipe will wedge itself into the cutting end and remain there, acting as a plug, but it shows up on pulling the pipe, and a new hole is driven. The method has proved as accurate, if not more so, than drilling and pumping. It is true, there is a shrinkage of core caused by compression, or displacement, or possibly by both, but I do not know the proportion of shrinkage, nor does anyone else. It apparently remains constant up to 15 or 20 ft. An operator soon learns his ground and can judge while driving whether he is getting the proper core. When the core is removed it is easy to judge. It is impossible to get too much core and consequently too much gold. It is possible, but not probable, that in a number of holes one may get too little core. Successful salting is impossible with ordinary care on the part of the operator. Panning the top end of the core, or barren material, detects salting.

As a proof of accuracy, and accuracy is relative as in all placer testing, I give the results of the testing and dredging that I did on a creek in the Solomon region. This work represents three seasons' operation with a small dredge. The holes averaged 8.3 per acre. In the first season the gold return was a little over the calculated amount, in the second season a little under, and in the third season a little over. Considering the entire acreage the production was 0.3% over the calculated yield. This comparison is based on bullion production from the total yardage dredged, and on carefully calculated test-values. The yardage was calculated at each clean-up, or once every two weeks, from the area staked in advance, and by daily soundings. The average value was determined by giving each hole in each cross-cut line and each line its proper weight. The inside diameter of the pipe was used in calculations and no discount factor was employed. The area dredged was a strip averaging 200 ft. wide. The prospecting was in lines of holes across this strip, the interval between varying with

conditions and the interval between holes ranging from 25 to 125 ft. The average depth of ground was 7.42 ft. The ground was dredged strictly in accordance with the drilling, the limits of 'pay' being staked in advance of the dredge.

To have dredging check so closely with drilling is unusual. This means simply that the method is satisfactorily accurate under favorable conditions. Of course my average number of holes per acre was high, probably the drilling and pumping method with the same number of holes per acre and using a discount factor would have been equally accurate. I do not mean that our dredge made 100% plus extraction; no one knows what a dredge extraction is, but it is generally guessed to be 80%. There is no practicable method of sampling dredge yardage, but this method of testing apparently makes the same extraction as a dredge, if I may express it thus, and no discount factor need be used.

Although I am not alone in this experience, I have no figures to quote from other operators. One operator, with probably the widest experience of any of us, says his ground dredges at least up to testing and sometimes over. This is his experience with several dredges over several seasons.

As to speed and cost, I give the following figures, obtained with an improved hand-rig: a crew of four men, including the panner, who occasionally helped on the rig, drove 139 holes in 20¼ days, averaging 51.41 ft. per 10-hr. day, in ground varying from 4.5 to 9 ft., and averaging 7.56 ft. This was done at a cost of 58½c. per foot, with the panner at $7.50, the remainder of the crew at $5, and board at $1.34 each per day. The cost per foot includes an item of 4c. for purchases, about half of which should properly have been charged to equipment. This is probably lower than the average cost for hand-drill work and is given merely as an example.

Illustrations of speed and low cost with a light power-rig are as follows: two men, one the panner, averaged on ground the same as above, 57.3 ft. per day, an average depth of hole of 7.1 ft. at a cost of 27.8c. per foot; on another test, two men and a panner averaged 70 ft. per day, the average depth of hole being 13.2 ft., at a cost of 34.3c. per foot. In another case two men and a panner averaged 87.2 ft. per day, average depth of hole 9.3 ft., at a cost of 23.7c. per foot. As an instance of deep ground, two men, one the panner, averaged 106 ft. per day, average depth of hole 20.2 ft., at a cost of 30c. per foot. In this case conditions happened to be exceptionally favorable.

The light power-rig should operate at one-third to one-half less cost than the hand-operated rig and at considerably less cost than the heavy power-rig. The number of men required depends on conditions. Usually two men and a panner make the most efficient crew. One man and a panner can handle the work but at less speed. In average ground a panner has little time for anything except panning. The consumption of gasoline is slight, not exceeding a gallon per day; repairs are almost nothing; pipe and rope replacements are varying items, but never high. On a long move the whole outfit is not a two horse load, and once on the ground horses are unnecessary. In case of transport by man or mule, the machine is easily dismantled. The light power rig, under conditions where pipe driving is impossible, can be used as a drilling and pumping machine. On account of its light weight it meets the need in inaccessible localities, where transport is difficult; also for preliminary work anywhere. An objection naturally raised to this machine is the small size of hole and pipe. A 6-in. hole has more than twice the area of a 4-in. hole, but how much more accurate is it? Theoretically, the larger hole is more accurate, but we do not get theoretical results in drilling.

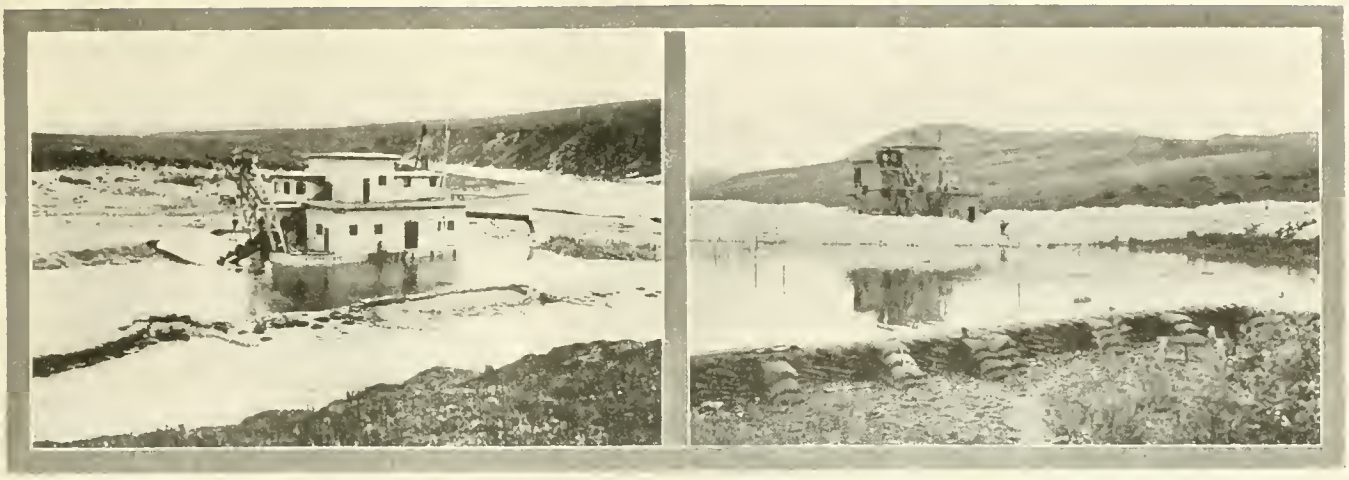
Dredge Practice. The first mistakes in the building and operation of dredges were natural and came partly from lack of accurate knowledge of what had already been done. The early machines, whether of land or water type, were too light to stand up even under favorable conditions. One of the early dredges was built on Dry creek, at the edge of Nome. This had a horizontal rotating movement mounted on rail-trucks and was equipped with buckets of 1-cu. ft. capacity, screen, table, stacker, etc. It was planned to dig a bedrock-drain to the Third beach. It had some novel features, but was altogether too light. Two similar machines were built, one of which was operated for several seasons on West creek, 30 miles east of Nome. This machine made a little money and demonstrated that, if properly constructed, it was fitted for certain types of deposit.

Another early dredge was operated on the Solomon river, near the mouth of Shovel creek. This was a floating machine, the bucket-line swinging on a boom from side to side while the hull remained stationary. The machine was re-built and finally abandoned for a more modern type. The first really successful dredge was built in 1905 by W. L. Leland, of the Three Friends Co., on Solomon river. This was a 5-ft. California standard machine, but steam driven. It is still operating but is now using electricity generated by a shore Diesel plant.

Seward peninsula finally developed a type of dredge adapted to existing conditions. In the States the Californian type of dredge prevails, as developed to suit deep and tight gravel. In the North similar conditions exist in places, and again there are others peculiar to the region that call for another type, or at best important modifications of the standard type. It is this type in particular that I wish to discuss.

In the United States the requirements for a one-dredge operation have been about as follows: favorable physical conditions with sufficient area and yield to pay for the dredge and a profit in 8 to 10 years, this period being taken as the life of a dredge. Operating factors are favorable, including climate, power, labor, and freight. Ordinarily the grade of the deposit is so low that these favorable conditions are necessary. It has been a question of big area, small profit per yard, and long life. Small rich areas that would last two years at a profit are the rare exceptions, and shallow depth is seldom a controlling factor.

On the Seward peninsula the new conditions are



A FLUME-DREDGE. A SCREEN-DREDGE.

rarely so favorable; usually there offers a small rich area of loose gravel from 5 to 10 ft. in depth that will last a 2½-ft. dredge from 12 to 18 months of working time; high cost of labor; a short season of four months; high cost of power and freight.

There were two ways of designing a dredge that would meet conditions: to ignore standards elsewhere; or to modify known standards. Both methods have been followed, resulting in the development of a type of machine that may not be perfect, but is at least satisfactory. This is called the flume-dredge. Although such a dredge was one of the first to be successful at Oroville, I believe the first builders of flume-dredges in Alaska, Kimball & Saupe, did not have this in mind, but took the natural course of designing a machine that would float, excavate, and dump into a flume.

THE FLUME-DREDGE. In principle the design is standard, except that a long flume replaces hopper, screen, tables, and stacker. The favorable conditions are shallow depth and loose gravel. These, together with the short life of the deposit, have made it possible to depart so far from standard construction that a first look at this dredge suggests a serious doubt as to its practicability. The construction is extremely light, in fact is almost flimsy, being built strictly for utility. One detail is original: In some machines the spuds are placed one-third the length of the hull forward so as to give a better distribution of tailing. All parts of the machine are in proportion. I shall mention only a few details. The lower tumbler is lubricated by a No. 2 grease-cup on top of the bearing. The digging-spud is made of wood with a steel shoe; the digging ladder is made of two light I-beams. The total weight is half that of standard construction, but the capacity is equal.

Operation is much the same as for a standard dredge and about the same crew is required, though there is no screen and stacker. The flume requires attention when slabby rocks are encountered. This flume is equipped with an undercurrent that removes the fine, but it is doubtful if the saving is as high, especially with fine gold, as with the screen type. It saves all nuggets, and, admitting that the loss is greater, this loss could easily be less than the additional cost of a screen-dredge.

The advantages of the flume type are: low first cost, rapid construction, low operating-cost, light draft (usually 28 to 30 inches), and ease in dismantling before moving. One builder has made a feature of a design that permits of quick dismantling and assembling, and reduces the loss of timber to almost nothing. In addition to the main framing being bolted, the hull-planks are bolted instead of spiked.

THE SCREEN-DREDGE. The screen-dredge on Seward peninsula follows closely to the standard design, in fact, many of them are of Californian design with no modifications. Some of them fit the conditions under which they are operating, while others are both too heavy and too strongly built. The most common mistake has been a natural one, the draft. In the States, draft is never an item of design on account of greater depth of deposit. A common argument against the screen-dredge is its loss of nuggets. This is taken care of successfully, I believe, by providing an area of large holes at the lower end of the screen. As to gold-saving, the standard table-area is larger than necessary; the gold, though it may be fine, is heavy, and lodges within 4 feet of the screen. The screen-dredge has its field, a choice between the two depending on the conditions.

DREDGING DIFFICULTIES. These, in Alaska in general, and on Seward peninsula in particular, are fairly well known but always magnified. Difficulties mean high cost, but not necessarily prohibitive cost. There are certain fixed facts that must be faced, namely: a working period of four, or at most, five months out of twelve; high wages and freight. The short season means sufficient time in the idle months to put the dredge in condition for continuous operation during the working period. It also means more or less grief in the winter time, if the dredge is not properly laid up, by reason of damage to the hull or machinery. The high wages means an efficient crew, but not quite proportionate to the wages.

Other conditions that affect yardage and cost are serious breakdowns that cannot be anticipated, shallow ground, and power. It is necessary to carry a complete

stock of parts for quick replacements during the operating season. There are no shops on the peninsula except at Nome. The ordinary dredge is equipped only with tools for light work.

Shallow ground means frequent steps and it may mean most difficulties in flotation. With a given width of cut and capacity of dredge the advance is naturally faster in shallow ground. This means lost time from stepping and moving lines, but not so much as might be thought, for little digging time is lost, as the ladder is hoisted only a few feet and lines are light and easily moved. If however, the ground is too shallow it may mean digging into bedrock for flotation or building dams to raise the water-level. In such a case the dredge of minimum draft decreases the depth of bedrock removed, or decreases the height of dams. A certain clearance is necessary under the hull, and in making this allowance the well-hole spill must be taken into account. As dredges are built, the open line has much less spill than the closed line. Digging barren bedrock is not profitable. It is much cheaper to build dams, although this may entail to the inexperienced a prohibitive cost. Dams can be built comparatively cheaply. A brief description of dam construction may be of interest, for as with every kind of work, there is an efficient method and an inefficient.

Coal-sacks are filled with gravel two-thirds full, the ends are left open and laid with broken joints in a wall. One tier will hold against 2 ft. of water. As the height increases the dam is braced with sack buttresses; 50 sacks will build 45 sq. ft. of dam, or a wall 15 ft. long and 3 ft. high. When the dam has served its purpose the sacks are emptied and re-used. An intelligent crew with good wheelbarrows and 'run-planks' becomes quite expert at this heavy work. Where the water has to be raised an average of 2 ft. for an entire season, the cost is 1½ to 2c. per cu. yd. dredged. Three factors determine the cost of such a dam: depth to bedrock, grade of ground, and filling for sacks.

The flume-dredge has proved suitable for shallow ground where flotation is a problem.

I shall attempt no further comparison between the screen-dredge and the flume-dredge. Conditions determine which is best suited. The flume-dredge is a new type, and has been adapted to unusual conditions.

Power. Gas-engines, or, more properly speaking, internal-combustion engines, furnish power except in the case of two boats at Nome that use electricity. In all cases except one, the power-plant is on board and consists of one or two engines. In the latter instance one of them drives only the pump. Both the vertical and horizontal types are used and each has its good points. There is one installation of Bolinder engines using a mixture of common fuel-oil and distillate; one installation of Mietz & Weiss engines uses a light gravity fuel-oil; and one Dow-Diesel shore-plant consumes a light fuel-oil. The others are gas-engines of different makes burning distillate.

The internal-combustion engine has proved satisfactory, but in many respects does not equal electricity. The requirements for an engine are severe; a continuous and variable load for 21 or 22 hours per day for four months shows up the weak spots. This type of engine is not nearly as well designed and as fool proof as the average automobile engine. But at worst, I believe troubles with the engineer are more frequent than troubles with the engine. Just when and where the first gas engine for dredge work was used, I do not know, but such installations elsewhere are few, as nearly all dredges are accessible to electric power. With proper installation, the internal-combustion engine should compare with electricity, except in districts of very low rate, favorably both in cost and reliability.

Application of power with internal-combustion engines is different from that of electricity with individual drives. Each machine must be equipped and operated with a clutch. Dredge manipulation is not as flexible, but it could be made nearly so. For example, the bucket-line must at all times run at a constant speed; also the winches, which usually have two fixed speeds. It requires a little closer attention on the part of the winchman and entails more work. An overload may slow down the bucket-line and also the engine to the point of stopping, and starting a gas-engine is frequently not easy. The most important feature of an engine for a dredge is an efficient governor, as there are sudden extreme variations.

An interesting feature in connection with the light power-drill and the flume-dredge is that men inexperienced in dredging elsewhere led the way and developed them.

Mineral Production of Italy

During 1914 the output was valued at $18,628,343, an increase of $139,715, according to a Consular Report. The following table gives the quantity and value of the principal ores:

Mineral	Metric tons	Value
Antimony	555	$ 7,203
Copper	88,953	318,181
Gold	205	21,588
Iron	706,246	3,131,842
Lead	45,538	1,759,167
Manganese	1,649	10,947
Pyrite	335,531	1,511,953
Quicksilver	119,223	736,321
Zinc	145,914	2,703,191
Graphite	8,567	50,151
Petroleum	5,542	267,401
Sulphur	2,371,705	5,609,199

Shanghai is the largest trading port in China. With a population estimated at a million people it has a considerable foreign colony, serving as a distributing point for the goods of many European and American business houses. Being close to the mouth of the Yangtze river, in which valley the British have important interests, there are many English-speaking people in the vicinity, and several English periodicals are published at Shanghai. The stock of silver at Shanghai is always large, generally about 60,000,000 ounces.

Flotation Practice in Missouri

By L. A. Delano

The flotation process was introduced by the St. Joseph Lead Co., at Flat River, Missouri, in the spring of 1914 for the purpose of treating slime. In the early days of the company all of the lead in the slime was lost, being washed into Big river through the mill-races. Later Frue vanners and slime-tables were used to treat a portion of the slime. The recovery was very small, however, compared with that obtained now by flotation.

The ores milled by the company consist mainly of disseminated galena in a gangue of dolomite. A small amount of pyrite, chalcopyrite, and blende are present in some of the ore. It is easily crushed and, the galena being soft, slimes readily. The ore is crushed to pass through 9-mm. screens, and is treated by jigs and tables. The overflow from the classifiers was the portion to be treated by flotation.

The Minerals Separation process was adopted, and flotation plants were built both in the Bonne Terre and the Leadwood mills of this company. The Doe Run Lead Co., a subsidiary, also installed a plant in the Rivermines mill. Each plant was similar, consisting of Dorr tanks for thickening slime, and a Minerals Separation machine for producing the froth.

The Bonne Terre mill produces the largest proportion of slime, it being approximately 20% of the ore milled. The plant there consists of four Dorr thickeners 8 ft. deep and 40 ft. diameter. They handle about 2800 gallons of water per 24 hours, containing approximately 2% solids, or an average of 400 tons of dry slime per day. The speed of the rakes is a revolution in 10 minutes. The slime settles readily, and the tanks maintain a clear overflow, which is used again for mill-circuit water. The thickened pulp averages 25% solids.

The agitation-froth machine contains 16 compartments. The thickened pulp from the four Dorr tanks is brought by pipe to a mixing-box at the head of the machine. The pulp passes through each compartment, froth being removed from the 'spitz' in front of each cell. The impellers are run at 290 revolutions per minute. Various speeds have been tried, but, for the power consumed, this produces as good a result as at the plants that use speeds of 320 and 350 r.p.m. The power consumed at Bonne Terre is 4.5 hp. per cell.

A crude hardwood creosote oil is used. Various oils and mixtures were tried, but none proved as satisfactory. The oil is fed to the machine in alternate compartments by a small 8-cylinder pump, driven from the line-shaft of the impeller-drive. Oil consumption is approximately 0.8 lb. per ton of dry slime treated, or a gallon of oil per ton of concentrate.

The feed to the flotation plant consists of slime of which approximately 90% is finer than 150-mesh. Material coarser than this is more economically treated on tables. The lead assay of the pulp varies at the different mills. At Bonne Terre it averages 5%. The tailing from the flotation machine averages 0.7% lead. About 88% recovery is maintained. The grade of concentrate averages 52%. The sulphides froth easily, producing large bubbles averaging 65% moisture.

When the plant was installed a mechanical rake was used to remove the froth as fast as it was formed. Later this rake was abandoned and the froth allowed to run over the edge of the 'spitz,' with results fully as good. The froth is broken up in launders and in the pump-box by a fine spray of clear water.

The concentrate was formerly pumped to settling-vats equipped with steam-coils. When a vat was loaded it was allowed to settle for four to five hours, the clear water was syphoned off, and the pulp dried by steam to 20% moisture. The concentrate was then shoveled into cars and shipped to the smelter.

In the summer of 1915 experiments were made to find a method of handling the concentrate-pulp more economically. Settling tests showed that this pulp could be thickened from 90% moisture to about 30%. A small Oliver filter was then tried to determine if it would treat this thickened pulp. The tests were very satisfactory, cakes being formed with moistures as low as 8%.

Consequently a 38 by 6-ft. Dorr tank for thickening the pulp and a 12 by 11½-ft. Oliver filter were installed to handle the flotation concentrate, and thus abandon the steam-drying vats. The filter was started in February, 1916, and has run continuously since. The pulp pumped to the Dorr tank contains 10% solids and is thickened to 65% solids. The rakes are operated at a speed of a revolution in 30 minutes. The pulp is fed into a well in the centre of the tank, in which a fine spray is used to break up most of the froth. A baffle-ring extends around the tank near the overflow to prevent the escape of froth.

The Oliver filter receives a pulp averaging 35% moisture. The cake is fairly uniform, being about $\frac{3}{16}$ in. thick, and averaging 13% moisture. The filter is operated with a speed of a revolution in 6½ minutes, and is driven by a 2-hp. motor. The vacuum is obtained by a No. 5 Roots vacuum-pump driven by a 35-hp. motor, and averages 25 inches of vacuum. The actual horse-power consumed is about 30. The pressure or 'blow' compartment on the filter is directly under the scraper.

As yet filtration in this region is in its infancy, the Bonne Terre mill having the only filter in the district. A filter-plant will be installed at both the Leadwood and Rivermines mills.

The St. Joseph Lead Co. treats 700 tons of slime per day by flotation in its two mills, while the Doe Run Lead Co. treats 500 tons. This approximates 15% of the ore milled. The tailing and grade of concentrate at the two plants are about the same.

The laboratory at Bonne Terre has been equipped with testing-machines of both the Hoover and Janney types. An extensive series of tests is being conducted to determine the best oils, size of slime, recovery, etc. Canvas tests are being made with the small filter to determine if lower moistures are possible. Tests are also being continued to obtain a higher grade of concentrate.

Working Data on Electrolytic Precipitation

By P. H. Crawford

IN writing this paper it is with the hope that it may be the means of bringing forth other data that may have been accumulated by those directly associated with the actual working of the process. No doubt there are many who have watched the process in all its stages and have noted many things that were of interest, and if all the data were brought together, with the ideas of each operator added, it might throw a flood of light on this method of precipitation and might prove the means of extending its usefulness.

After reading the able article* by Mr. G. H. Clevenger, in which he thoroughly covers the subject up to and including the first six years of its installation at the Minas Prietas works, I venture to give information covering a later period, for, with the knowledge gained during the previous six years, we were enabled to make many changes that not only gave us a better product to smelt, but were the means of reducing the cost.

As stated by Mr. Clevenger, the clean-up at Minas Prietas was crude, by reason of the way in which the boxes were built, but this was somewhat improved on making arrangements to treat some refractory tailing, the whole box-system being changed during the shut-down necessary in order to convert the mill to an all-sliming process, which was essential for this tailing, a rough analysis showing the following base metals: manganese 2.7%; iron 2.8%; copper 0.24%; and lead a trace. About 25% of the silver was locked up with the manganese.

The chemicals consumed, per ton of tailing, during the year covered by this article, were as follows: cyanide 4.5748 lb. 100% KCN and lime 12.32 lb. Lead acetate was tried, but it did not help in lowering the residues or reducing the cyanide consumption; but, strange to say, on 90% of the alternate charges that were so treated, using from 0.5 to 1.5 lb. per ton of tailing, it gave a higher residue.

During the shut-down the four boxes used for slime-solution precipitation were cleaned out, all the up and down guide-sticks being removed, the adhering calcium crust scraped off, those in good condition being replaced and the balance made up from new strips. On replacing, the spaces were increased to hold 20 anodes and 21 cathodes; this reduced the distance from centre to centre and lowered the voltage. The change to more cathodes and less anodes was due to the fact that by starting with a cathode and ending with one we saved two tons of lead and secured the same plating surface. The boxes, as has been stated, were in tandem, in the first two all the compartments were filled, each with 20 anodes and 21 cathodes, and wired in series of three. This gave 960 sq. ft. per series and 0.3646 ampere per sq. ft. of plating surface, when using 350 amp. In the last two boxes, only the first 8 compartments were filled and these wired in series of 4, thus giving 1280 sq. ft. of surface and at 350 amp. gave 0.2734 amp. per square foot.

The monthly record is shown in Table I, after the boxes had been in operation six months. This shows the great variation from month to month in cyanide regenerated, alkalinity loss, and percentage of metal precipitated, nothing being constant except the ratio of gold and silver precipitated.

To arrive at the average work during a year, the following résumé has been made from the various data:

TABLE II

Average of 12 months' operation.

	Gold	Silver, Oz.
Head assay-value solution	$1.5835	1.2347
Tail assay-value solution	0.3587	0.2613
Value precipitated	1.2248	0.9701
Percentage precipitated	77.317	78.594
	Cyanide %	Alkalinity %
Head solution tested	0.04369	0.041783
Tail solution tested	0.05997	0.035566
Amount cyanide regenerated	0.01628	
Amount alkalinity loss		0.006217
Percentage cyanide regenerated	37.262	
Percentage alkalinity loss		14.879
	Copper, %	Zinc, %
Head solutions assayed	0.0851	0.0069
Tail solutions assayed	0.0780	0.0066
Electric current used	334.25 amp.	33.08 volts

In the above table is given the average copper and zinc carried by the head and tail solutions, these not being shown monthly as I had failed to so enter them in my notes, but are the average for the year.

The resulting tail solution was too rich to use as a wash in the slime filter-press, though followed by a good water-wash, so a small 9-compartment zinc-box was placed at the foot of the electric boxes, in the first 8 compartments zinc shaving being used, cut from No. 9 sheet. Fifty to 75 tons of solution were passed through this box in 24 hours. A daily consumption of 10 to 12 lb. of zinc took place. This box was cleaned daily when treating 75 tons and every second day when passing 50 tons. Above the screen each compartment measured 18 by 28, and 18 inches deep. Table III shows a year's work by this small zinc-box.

The cathodes were of tin-plated sheet-iron and the anodes were of two kinds, as mentioned by Mr. Clevenger, lead sheet and lead rods, both being the same as used at Virginia City, except that the 4-in. lead lug stood up 4 in. above the anodes. These anodes were peroxid-

ized in a 1% solution of potassium permanganate to which was added 1% H_2SO_4. When we first began using the lead rods we found they did not last as long, or rather showed signs of deteriorating sooner than they should; this was thought to be due to the rougher surface of the cast-rod. A two-size grooved double wheel-roll was made, the first size slightly smaller than the cast-rod; by the use of two cranks these rolls were turned by hand and the rods passed through the rolls up to the shoulder and back, then through the smaller and back. With this treatment they received the same surface as the plates and gave as good results. We soon found that the frames got loose and out of shape, so it became necessary to tack wooden strips diagonally across the crate, one on each side. These anodes were peroxidized in a box made to treat three at one time, in which four heavy lead anodes were hung; for while being peroxidized the anode takes the place of a cathode. This box was made to hold just a ton of solution when two inches above the top of the anodes; it was thus an easy matter to make up fresh solution, or add the amount of permanganate necessary to bring it up to standard, or replace the water being broken up by the current. This box was 2 ft. 4 in. wide, 3 ft. long, and 4 ft. 9 in. deep.

Many substances were tried for anodes, some with strange results. Graphite was tried, both in slab and rod shape; in both cases we found that they would not last long. For the first few days they would remain, so far as one could note, in about the same condition as when first submerged, but later they would begin to disintegrate just below the surface of the solution. On painting this section with P & B paint the disintegration would take place just below the paint. It would appear from the above that there was more resistance in the graphite than there was in the solution and the

greater part of the current left the anode at the first opportunity.

Later tin plates were tried, these were $\frac{1}{8}$ inch thick, they were fastened to a wooden top strip the same as used for the lead sheet anodes but without lugs, and in place of the No. 14 bare copper wire with which the anodes and cathodes were attached to the 1 by $\frac{3}{4}$ in. copper cross tapes, a piece of insulated copper wire was soldered to the corner and this passed through the lug-hole. Three of these were tried, receiving the same peroxidizing treatment as the lead ones, which gave them a steel blue color. After a month they were in the same condition as when first placed in the boxes, except for a slight white crust on the outside. Sixty of these plates were ordered and as fast as made ready they were put in the boxes in place of the lead ones, which were from time to time removed; these remained in good condition, the cathodes on both sides showing as much precipitate adhering as those opposite the lead ones. These 60 tin-plates now being ready, on the first clean-up day they were all collected and placed in a series by themselves. Greatly to our surprise, on the third day we found that over one-half of them were more than half-gone and the others badly pitted, having holes clear through them. Of course, they all had to be removed. What tin was left was smelted down and mixed with lead, $\frac{2}{3}$ of the former being added to $\frac{3}{4}$ of the latter, this making a good solder, which was cast in the rod mould, made to cast six at one time. Having as much solder as we could use on the boxes for several years and thinking it worth while to test this mixture, two frames were fitted with 12 of these rods and put in the boxes as anodes, two years later when the plant was shut-down these two anodes were in very good condition. Had there been enough to fill one series there is no telling but what they would have met the same fate as the pure tin anodes.

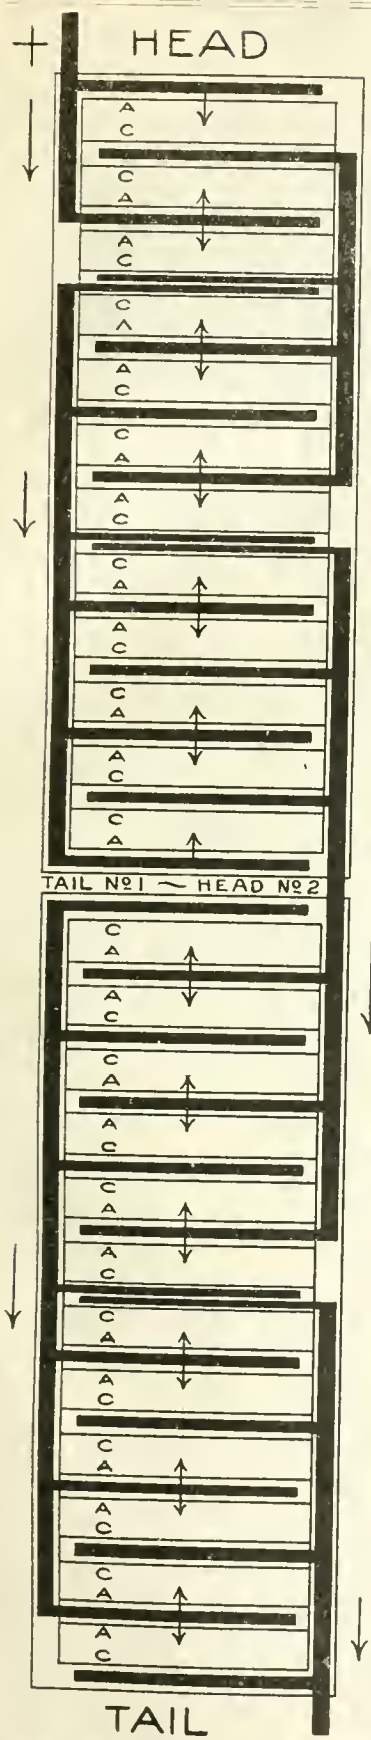
When the plant began using lead anodes they were ordered direct, coming in just the right size. These lasted a long time, many for over three years. Later, having accumulated many discards they were smelted in a reverberatory furnace and the clean lead run into moulds. These pigs were melted in an iron pot, in both cases using wood for fuel, and cast into slabs $\frac{5}{8}$ by 12 by 24 inches. A set of rolls was placed in commission and when these slabs were passed through eight or ten times the result would be a large sheet of rolled lead that was cut-down to the size needed for an anode, which was 25 by 48 inches. The dross, which was a mixture of slag and litharge, was ground in a ball-mill, sampled, and shipped to the smelter. I am unable to find in my notes the assay-value of this product, but it carried about $100 in gold and silver.

It was noted, as time went on and the old lead was used over and over again, that the resulting anodes did not last as long as when new lead was used; this was supposed to be due to the gold, silver, and copper carried by the lead, these metals being, by the action of the current and cyanide, re-dissolved, leaving the anode with a pitted surface and more liable to dissociation. As for the gold and silver, it was thought there was no real loss, for the reason that on returning the anodes to the boxes these metals would be recovered about as fast as others were being tied up.

After a time the sheet-lead anodes would become hard and brittle, and when one became buckled and was removed to be straightened it was hard to bend it. When they became so old that they would start to crumble, it was found that by placing them flat on the floor and beating with a hammer a hard brown crust about $\frac{1}{16}$-inch thick would crack off each side, leaving a thin sheet of metallic lead. A shipment of this crust assayed $33.07 gold and 66.80 oz. silver.

On starting to clean a box, the solution was turned off, the current was by-passed through an insulated one inch cable by using a knife-switch. The cathodes were then rubbed down with a brush and the box allowed to settle for two hours. About two-thirds of the way down wooden plugs were fitted into each compartment; these were first removed and the solution drawn down to this level; bags made from drilling were then tied over 1¼-inch iron cocks, which were about eight inches from the bottom; when the solution had drained down to these, iron cocks on the opposite side, which were flush with the bottom and drained into a wooden launder running to a cement sump, were opened and all the product that would run was flushed to this sump, which was connected by pump to a small filter-press. Four anodes and five cathodes from the centre of each compartment were then removed to allow men wearing rubber boots to enter and with scoops and small hoes fill buckets with the settled precipitate, the buckets being passed up to a man outside. Three men worked at one time, one in each compartment, taking about an hour to each compartment or four hours for a whole box. The outside man carried the precipitate to a small iron tank, fitted with a filter-bottom and having mechanical agitators driven by the same motor that ran the filter-press pump. Inside this tank was a small box that had a 10-mesh screen for a bottom, all the precipitate being passed through this box by using a water hose. Any calcium crust or pieces of broken anodes were thus kept out, and on being washed were piled to one side. In the tank was fitted a 1½-inch pipe for a decanter; when the level of the wash-water reached within a foot of the top, this decanter was lowered and the water, which, on account of the agitation carried the fine, was run to the filter-press. After a clean-up was finished the decanter was lowered and all the fine run to the press, the agitator was then stopped and the vacuum turned on and the precipitate dried to within 20% moisture; it was then removed to the dryer. Before installing this tank and screen-box much of the calcium crust and fine lead was smelted with the product.

As will be noted, the difference between 'heads' and 'tails' on the copper contents of solution was only 0.007l%; to try to remove a greater amount, a separate copper-box was installed in one of the lower unused compartments. This was wired in one series having 15 anodes and 16 cathodes which received the whole current and, when using 350 amperes, gave 1.46 amp. per sq. ft.



The first is wired in series of three. 60 anodes and 63 cathodes, giving a plating-surface of 960 sq. ft. Using 350 amperes = 0.3646 amp. per square foot.

The second is wired in series of four. 80 anodes and 84 cathodes, giving a plating-surface of 1280 sq. ft. Using 350 amperes = 0.2734 amp. per square foot.

The third and last in the head box is wired in series of five. 100 anodes and 105 cathodes, giving a plating-surface of 1600 sq. ft. Using 350 amperes = 0.2188 amp. per square foot.

The first in the second box is wired in series of six. 120 anodes and 126 cathodes, giving a plating-surface of 1920 sq. ft. Using 350 amperes = 0.1823 amp. per square foot.

All the anodes and cathodes in the above are spaced 3 in. apart.

The second is also wired in series of six, but the anodes and cathodes are spaced 2.5 in. apart, giving 24 anodes and 25 cathodes to each compartment. 144 anodes and 150 cathodes, giving a plating-surface of 2304 sq. ft. Using 350 amperes = 0.1519 amp. per square foot.

If a special box were built with 13 compartments, the last could be wired up in series of 7 and spaced 3 in. from anode to cathode, giving 2240 sq. ft. of surface and using 350 amperes would equal 0.1562 amp. per square foot.

The anodes were made just the same as the others but were $\frac{1}{4}$ in. thick, both the anodes and cathodes being attached by a $\frac{1}{4}$-in. copper wire to lower the resistance. The anodes were enclosed in sacking to keep any lead out of the precipitate and in case of buckling with this high current diminish the chances of a short circuit. The head solution assayed 0.072% copper and the tail 0.069%. The resulting precipitate gave 76% copper and 13.40% gold and silver combined. After running about a month we did not think the recovery warranted the power consumption necessary to precipitate, so this compartment was cut out.

In the day-time when an anode buckled, which was not often during the last few years, or when precipitate lodged between the cathode and anode, and a short circuit was caused, the connecting copper wire would smoke if it was a bad short-circuit, the smoking being caused by a little candle-grease, which would adhere to the wire as they were daily passed over with a candle attached to a stick to locate warm wires. At night if a bad short-circuit took place it would be noted by the wire becoming hot and showing a dull-red light. When the anode was new the buckled centre could be pressed back in place by inserting a wooden stick between the buckled anode and the cathode, and forcing it back into shape.

The main copper tapes along the sides of the boxes that carried the whole of the current were $1\frac{1}{4}$ by $\frac{1}{4}$ in. and those running crosswise were 1 by $\frac{3}{16}$. The latter were bolted to the main tapes and then soldered on both sides. These tapes would carry the current without getting hot or warm, unless a poor connection was made.

In the last empty compartments there was formed over the surface of the solution a crust, in thickness from a film to $\frac{1}{16}$ in. and in color from white to a light-lemon tinge, the thickness depending on the length of time it remained undisturbed. On punching several holes in the crust, to allow the solution to come on top, it would break off in slabs and sink to the bottom. A rough analysis gave 72.5% $CaCO_3$ and 1.3% Cu and assayed $76.89 gold and 74.78 oz. silver. No crust was formed on the last compartment or, if formed, it was carried away before it could make a film, as the solution overflowed the whole length of the end into a launder. No crust was formed in the compartments in use, due no doubt to the disturbed condition of the surface, which was caused by the gases being given off, oxygen at the anode and hydrogen at the cathode. These gas bubbles as they came to the surface seemed to burst and would throw a fine spray of solution upward, this spray was hard on the connecting copper wires, for it was at this point that they would give way first, it being harder on the cathode wires than the anodes, which were protected by the 4-in. lead lug. P & B paint was tried, but did not last long, and could only be renewed when the cathode was out of the box, as it would not adhere on a wet surface.

The best precipitate, both as regards percentage of metal and the ratio of gold and silver to copper was always found in the head compartments and would diminish throughout the remainder of the compartments. To try to overcome as much as possible the precipitation of calcium that seems to take place when the metal contents of the solution diminish, the writer suggests the wiring shown in the accompanying diagram.

As will be seen the two boxes are placed in tandem,

the first is wired in series of 3, the next in 4, followed by 5, the last two both being in series of 6, but the last six compartments have 24 anodes and 25 cathodes, this spaces the anodes and cathodes 2.5 in. apart, but as the current will be very low there should be little danger of buckling and thereby short-circuiting. This should not only lower the amount of calcium precipitated, but give longer life to those anodes receiving such low current.

The cathodes take on a plate of copper and, of course, some silver and gold, but if this is not scraped with some sharp instrument they will last during the life of the average plant. However, the iron once being exposed they soon become pitted and by handling begin to break.

During the year covered by this account there was treated an average of 4920 tons of tailing per month, with an average of 1 : 3 of solution; there was precipitated about 492 tons of solution per day, the yearly average showed a saving in cyanide of 0.01628% per ton of solution, which would be 160 lb. per day, or 4800 lb. for a 30-day month, which at 20c. would make a total saving of $960.

The total amount of new lead used during this year was 8677 lb. The total amount in use in the boxes approximately 80,000 lb. If the average life of an anode is two years, and there is no doubt that by using the recovered lead over again it will last that long or longer, then the consumption of lead would be not over 40,000 lb. per year or 3333 lb. per month, which at 5c. per lb. would be $166.65 per month.

During this year I have the costs for only one month's operations and during this period we treated 5360 tons of tailing; the costs were as follows:

	Labor	Supplies
Labor	$209.25	
Power	38.35	$135.67
Supplies		34.96
Repairs	16.75	1.75
Total	$264.35	$172.38
Total labor and supplies		$436.73

As the cost was low for supplies in this month, no doubt a small lead charge was made, perhaps not over 500 lb., but by adding the lead average found above ($166.65), this would give $603.38, which is high on account of the charge included in the total supplies, but on the average monthly tonnage this would be 12.3c. per ton of tailing. When one stops to think of the saving in cyanide, the actual cost for precipitation was nothing, had the saving been credited to the department whence it was derived.

The generator used was a type G 30 V, 500 amp. speed 750, built by the Eddy Electric Manufacturing Co. and was run by a straight-line steam-engine of 25 hp., making 272 r.p.m. Power cost, including labor and supplies, was about $10 per hp.-month, which was high, owing to the price of wood used for fuel.

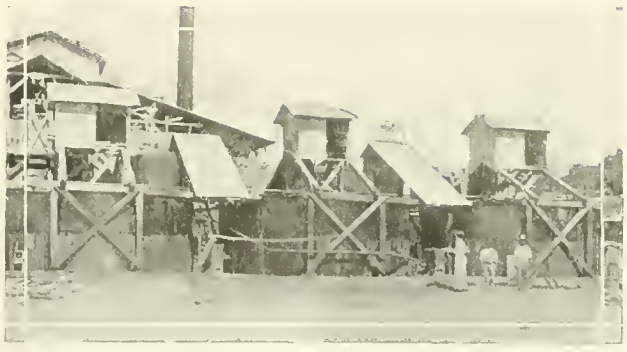
Copper production of Alaska from 13 mines in 1915 totaled 86,509,312 lb., extracted from 369,600 tons of ore. The value was $15,139,129; also $153,121 gold and $455,204 silver.

Tin Output

The tin production of the world is about 120,000 long tons annually. Over half of this comes from the Federated Malay States, while Bolivia contributes 18%. The Dutch islands of Banka and Billiton, in the Java sea just south east of Singapore, rank next to Bolivia in importance. Cornwall produces 6000 tons annually, as do also South Africa and Nigeria combined, while Australia and China contribute 4000 tons each. Cornwall has been famous for tin since prehistoric times, and forty years ago its output was at the rate of 12,000 tons per annum. The North American continent produces practically no tin—only a trivial amount from Alaska. The bulk of the American consumption of tin—and the United States is the largest user of tin in the world—goes to make cans for preserving our plentiful output of salmon, beef, vegetables, fruit, etc. The valuable property of not tarnishing and of being resistant to the decomposing action of air, water, and the common acids and alkalies is what makes tin preferable for plating iron for making cans. Tin ore from Bolivia, unlike Straits tin, is said to contain iron, which lessens the adhesion of the tin to iron plate. This militated against the importation of Bolivian tin into the United States, until the method of electrolytic refining became practicable. The American Smelting & Refining Co., which recently completed a tin smelter at Perth Amboy, New Jersey, had the foresight to arrange with the Bolivian government to ensure that unfavorable tariffs for the export of tin concentrate from that country will not be enacted, as was done in the case of the smelter built in 1904 at Bayonne, New Jersey, to treat concentrate from the Malay States. The Bolivian minister of foreign affairs, it is understood, gave a signed note of assurance that no discrimination would be made by his government against the United States in the matter of export duties on tin or other metals. In early times, before the coming of the Spaniard, the natives of Bolivia made use of tin as an alloy with copper to make bronze. The copper they obtained from the Corocoro region of Peru, where, incidentally, the Anaconda Copper Mining Co. recently has been investigating mines and prospects. The tin of Bolivia is found associated with silver, and some of the mines were worked originally as silver mines.* The region lies at an elevation of 8000 to 17,000 ft. above the sea, being on the bleak Bolivian plateau. Previous to the War the smelting of Bolivian tin was divided about equally between Germany and England. Much of the Straits tin is smelted by the Straits Trading Co. on the island of Pulo Brani opposite Singapore. The Dutch government has a smelter at Banka, and markets its product both in Holland and Java. One reason why Straits tin has dominated the market is because most of it is recovered from alluvial deposits that are worked cheaply by Chinese labor and dredges. The Nigerian tin also is all of alluvial origin.

*See articles on Bolivian tin mines, by Francis Church Lincoln, M. & S. P., March 27, May 8, and July 24, 1915.

THE CYANIDE PLANT.



MECHANICAL AGITATORS.

Cyanidation at the Comacaran Mine, Salvador

By A. B. Peckham

INTRODUCTION. The mill of the Comacaran Gold Mining Co. is close to the village of Hormiguero, district of San Miguel, Salvador. To go to the mill you take a Panama steamer for the Port of La Union, on the Gulf of Fonseca. This is a journey of two or three weeks, depending on the number of ports of call. From La Union to San Miguel, a city of 30,000, is a 40-mile journey by rail. From San Miguel to the mill is 12 miles, the trip being made on mule-back. The country is comparatively level with low rolling hills, but the roads are such that no vehicle other than an ox-cart can be used. The other lines of communication between Hormiguero and the outside world include a Government telephone and telegraph line, a cart road to La Union, and a trail to the famous mines of Divisadero and San Sebastian.

THE ORE is an argentiferous sulphide containing 4 oz. of silver and 0.35 oz. of gold. The gangue is quartz and limestone. The associated minerals are pyrite, a little malachite, and iron oxide. The ore is extremely hard. It is brought to the bins by an aerial tramway. From this the ore is trammed by hand in side-tipping sand-cars to the mill-bin, which is of square type.

CRUSHING. The larger pieces of ore are fed by hand to a jaw-breaker of the Blake type, which crushes to 2 inches. Ore of less size is tipped directly into the mill-bin. The ore is fed to the stamps by Challenge feeders of the suspended type. There are 25 stamps, 15 of which are 1300 lb. each and the remaining 10 are 1280 lb. each. Dropping 7 inches at a rate of 108 drops per minute, the duty per day is 7 tons through 3-mesh screen. The stamps crush in a cyanide solution containing 1.5 lb. cyanide and 1.5 to 2 lb. lime per ton of solution. The shoes last 125 days and the dies about 140 days. Both are of forged steel.

TUBE-MILLING AND CLASSIFICATION. The pulp from the batteries flows to a Dorr duplex classifier. The slime from this classifier, which is free from sand, goes to one of two home-made thickeners. The sand is fed to two Allis-Chalmers tube-mills of the Tonopah type, together with enough battery solution to make a mill-feed containing 60% of sand and 40% of solution. These mills are 4 by 20 ft. They revolve at 30 r.p.m. The sand-discharge from these two tube-mills is diluted with battery solution and flows to a Dorr simplex classifier. The sand from this goes to a 4 by 22-ft. Krupp tube-mill. The liners of this mill are corrugated cast-iron plates, that last six or seven months. The pulp-discharge from this mill is raised by a Frenier pump to the duplex classifier, taking the battery-pulp, thus closing the circuit. The slime-discharge from the simplex classifier, containing fine sand, flows to one of two Butters-Mein revolving distributors for the final separation of sand and slime. These distributors discharge the slime over rings in the centre.

SLIME TREATMENT. The slime from the collectors is raised by two Frenier pumps to the two home-made continuous thickeners. The slime is thickened to a pulp containing 25% dry slime, as this has been found the most economical and efficient dilution. The thickened pulp is raised to two mechanical agitators by air-lifts. These agitators are a combination of mechanical agitator and Parral tank. The circulation of the pulp, which is ordinarily done in mechanical agitators by means of pumps, is accomplished in these tanks by two air-lifts. It takes about 10 hours to fill one of these agitators. When one is filled, the amount of cyanide necessary to raise the pulp from 1.5 lb. cyanide per ton of solution to a strength of 2.5 lb. per ton, together with 10 lb. of lead acetate, is put into a basket suspended under the spout of one of the air-lifts. The air is then turned on and the pulp agitated for eight hours. At the end of the agitation the pulp is pumped to one of three Pachuca tanks. The agitator is now empty and ready to take the stream of pulp from the thickeners when the other agitator becomes full.

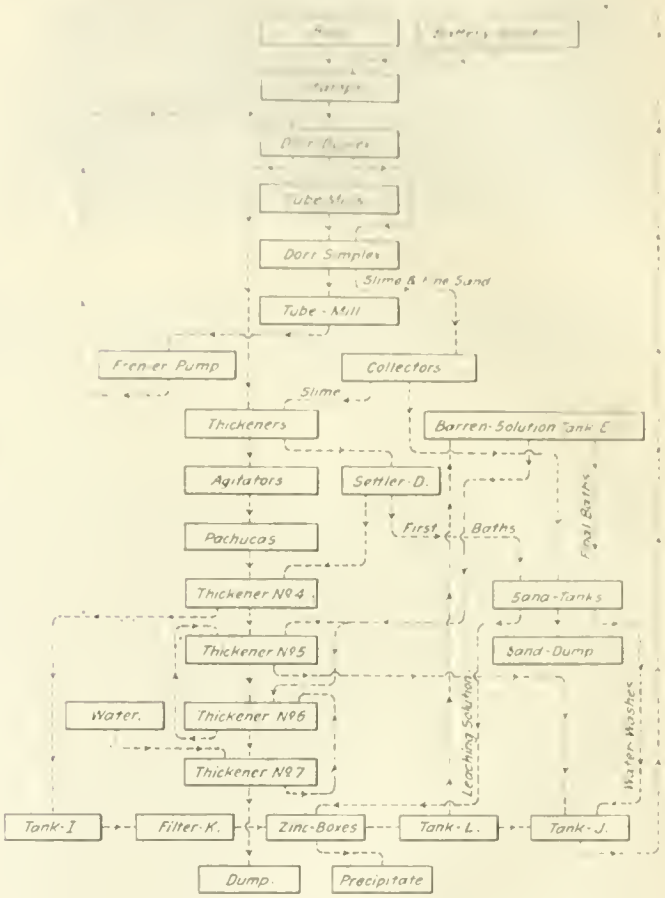
The slime is agitated further in the Pachuca tanks for 20 hours. Then pulp in these tanks is drawn off to the first of four Dorr thickeners in a counter-current continuous-decantation system. The time occupied in

lowering a Pachuca depends on the condition of the filling. Ten hours is the time generally occupied in lowering a Pachuca.

Continuous Decantation.—There are four continuous thickeners used in washing the treated pulp. Three are 28-ft. Dorr thickeners and the other is home-made. The thickeners are numbered 4, 5, 6, and 7. The pulp from the Pachuca tanks, which contains about $3.50, together with the clear overflow of battery-solution from thickener No. 1, which contains $1, goes to thickener No. 4. The clear overflow from No. 4 goes to the rich-solution tank, which assays about $1.75 per ton. This rich-solution tank is labelled *I*. The solution then goes to a filter or clarifying tank *K*, thence through the zinc-boxes to the barren-solution tank *L*. The underflow from thickener No. 4, which contains 40% of dry slime, flows to a Frenier pump, where it is mixed with the overflow of thickener No. 6 and raised to thickener No. 5. Before entering the latter the pulp is further diluted by a stream of barren solution from tank *E*.

The overflow from thickener No. 5, which contains value to the extent of $0.50 per ton, goes to the battery-solution tank *J*. The pulp-underflow of No. 5, which contains 40% of dry slime, is mixed in a second Frenier pump with barren solution from tank *E* and with the overflow of thickener No. 7, which assays $0.10 per ton, and is raised by the Frenier pump to thickener No. 6.

The overflow from No. 6, which contains $0.25 per ton, goes to wash the underflow of No. 4, as stated above. The underflow goes to a third Frenier pump, where it is washed with a stream of water and raised to the last thickener in the series, No. 7. The overflow of thickener No. 7 goes to wash the underflow of No. 5, as stated above. The underflow of No. 7 runs to waste. This underflow contains 40% of dry slime that includes $0.55 of insoluble metal. The 60% of moisture assays $0.08 to $0.10 and titrates 0.87 lb. cyanide and 0.75 lb. lime per ton of solution. The accompanying table shows the average results for two months. These are normal results.



FLOW-SHEET OF COMACARAN MILL.

It was observed, contrary to the claim of manufacturers, that the thickened pulp came out purely by the hydrostatic head, the arms serving only to prevent the bottom from building up and to rake any hard slime that falls from the sides toward the centre.

The continuous-decantation system was put into successful operation only after several months of experiment and annoyance. In the first place the angle of the rakes had to be changed to 15° in place of 5° or 7°, as sent by the factory. This change was made necessary by the continuous sticking of the thickeners. Instead of changing the angle of the rakes on some of the thickeners, they were run at a speed of one revolution per two minutes. The thickening qualities were not impaired.

In the beginning, the pulp from the Pachuca tanks was run into the first thickener of the series with the idea of getting rich heads for the zinc-boxes. The solution from the first thickener was then $3 to $4 per ton. It was found that the remaining thickeners were unable

to bring the unwashed residue to within $0.25 of the value of the washed residue. This difficulty was met and overcome by running all the clear overflow from thickener No. 1, which thickens the battery-pulp, into the first thickener of the series. This use of the battery-solution, besides lowering the pulp within practical limits, also causes all solution coming from the batteries to be precipitated before returning. The solution that goes to the battery-solution tank at the head of the mill is in this way brought down to $0.25 or $0.30, which is an advantage. The precipitation of the battery-solution also gives the great quantity of barren solution needed for the system.

The advantages of the system are:

1. Low operating cost.
2. A large and elastic capacity.
3. Extreme simplicity and freedom from the mess and work characteristic of slime filtration.

The disadvantages of the system are:

1. The enormous amount of barren solution needed in a plant using the system and necessity of precipitating a great amount of low-grade solution.
2. The impracticability of the system with slime that resists settling, such as some oxidized ores and ore from surface workings.
3. The ease with which the system is thrown out of adjustment by a sudden run of rich ore, especially if the system is being worked to capacity. Double the mill-heads and you have to double the amount of barren solution and water used, or be content to see your tailing doubled. Often the barren solution is not obtainable and the mill cannot assimilate more water.
4. A large amount of water is used and run to waste.

In conclusion it can be said that owing to the low operating cost and the large capacity of the system, it is ideal for mills handling a large tonnage of low-grade ore. It is not the ideal system for a mill that has to handle much ore that resists settling, nor where there is little water.

Clarification. The solution to be clarified is pumped to two steel tanks, in each of which is a nest of 16 Butters filter-leaves. The solution is drawn through the leaves by a vacuum-pump that discharges the filtered solution to the small steel settling and distributing-barrel in the precipitation-room.

Precipitating and Smelting. The solution to be precipitated flows by gravity from the settling-barrel to five zinc-boxes of standard design. The zinc consumption is 0.88 lb. per ton of ore treated. The precipitate is washed into a small steel filter-tank that is connected to a vacuum-pump. The damp precipitate is scooped from the filter and placed in drying-pans. The dried precipitate, including zinc shorts, is mixed with 12% of borax, 10% of sodium bicarbonate, and 18% of assay-slag. The charge is melted down in a Monarch tilting-furnace, using crude oil as fuel. The bar is made in one melt, as double melting was not found worth the expense.

Sand Treatment. The sand from the collectors, after four hours of draining by vacuum, is charged into the leaching tanks. A tank when charged has 80 lb. of cyanide placed under the solution-pipe, the drain-cock is closed, and the tank is filled with battery-solution (80 lb. of cyanide per tank represents 1 lb. of cyanide per ton of sand in the tank). At the end of 12 hours the drain-cock is opened and the tank is allowed to drain for 12 hours. This treatment is repeated twice. This is called the rich-solution treatment and lasts three days. At the end of the third day the drain-cock is left open and baths of barren solution are applied every four hours until the end of the treatment. For 24 hours before a tank is discharged water-baths are applied every four hours and the tank is dried finally by vacuum. The tanks are discharged by hand. Peons shovel the sand into cars beneath the tank and tram the sand 300 ft. to the dump. The work of discharging the sand-tanks is done by contract. The peon contractor receives 24 pesos ($8 at the present rate of exchange) for charging and discharging an 80-ton tank in the manner described.

A pound of aluminum has over three times the volume of a pound of copper. Thus, if the output of the Aluminum Company of America (including its Canadian subsidiary, the Northern Aluminum Company of Canada) estimated for 1914 at 108,000,000 lb., were used entirely for purposes for which volume is the controlling factor, the amount would be equivalent to over 325,000,000 lb. of copper, which is more than the annual output of either Montana or Michigan. Practically no opposition exists to the control of the production of aluminum in the United States and Canada by the Aluminum Company of America. The Southern Aluminum Co. was constructing, previous to the War, at Whitney, North Carolina, a plant designed to give employment to 1200 men. This company, a branch of the L'Aluminium Française, the French company which is estimated to have produced 29,700,000 lb. in 1914 chiefly from works in France, is now reported to have been sold to the Aluminum Company of America, which has various plants in Pennsylvania, Tennessee, New York, New Jersey, and Canada, and is understood to be controlled by the Mellon family of Pittsburg. This organization, with a capital of $20,000,000, makes no regular statement of earnings, but its president recently announced at Detroit that a profitable return on capital had been earned for several years much of which, however, had been reinvested in improvements. Constant experimenting has been in progress at the company's plants for years; many changes and great expansions have been, and are being, made. Other foreign producers of aluminum have been the British Aluminium Co., which in 1914 is estimated to have produced 19,800,000 lb., mostly in Great Britain; the Aluminium Industrie Aktien Gesselschaft, which in 1914 produced 30,800,000 lb. from Switzerland and Austria; and the Societe D'Aluminio, Italy, which in 1914 produced 1,700,000 lb. The use of aluminum is increasing rapidly; it is in demand for parts of automobiles, utensils, soldier's kits, and as a precipitant in cyaniding plants.

CONCENTRATES

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

TAILING at the Nipissing mine, Cobalt, is to be treated by flotation.

QUERIES on mining generally answered by the U. S. Geological Survey amounted to 1000 each week in 1915.

METAL MINES in the United States employed a total of 1,009,236 men in 1914. Of these, 3193 were killed, equal to 3.16 per 1000.

COST of lining basic converters at the Old Dominion smelter, Arizona, is 5.5c. per ton of copper bullion, against $1.80 with the old acid-type converter.

PURE METALLIC VANADIUM was first prepared in 1901. It is the hardest of metals, being above 7; the specific gravity is about 5.5; the melting-point is 1680° C.

GEARS driving flotation propellers in adjoining cells should revolve in opposite directions, so as to equalize strains on the machine and the power transmission.

DRILL-STEEL has a carbon-content from 0.6 to 1.1%. A steel of 0.9% carbon is recommended, although it requires a little more care in tempering than one of lower carbon.

TO PREPARE and equip the Inspiration mine at Miami, Arizona, for the mining and treatment of 5,000,000 tons of sulphide ore per annum (14,400 tons daily) cost $625 per ton for equipment and $208 for advanced underground preparatory work, a total of $833 per ton.

ACCIDENTS at mines and works are required by law to be reported in Alaska, Arizona, California, Colorado, Idaho, Illinois, Maryland, Michigan, Minnesota, Missouri, Montana, Nevada, New Jersey, New York, Oregon, Pennsylvania, South Dakota, Washington, and Wisconsin. Most of the legislation dealing with this phase of mining is of recent years.

A PORTABLE TELEPHONE, made of aluminum and weighing but 2½ lb., is to be used by patrolmen in the National Forests. For exploratory work in sparsely-settled regions, this instrument is an undoubted convenience. It is said that a field man equipped with this telephone and a few yards of wire can 'cut in' anywhere by throwing his emergency-wire over a telephone line.

LARGE BLASTS of rock are becoming more common with big-scale mining. An immense one took place on November 21, 1915, at Chuquicamata, Chile. In an adit 90 metres long, connected with 20 smaller adits, was placed 67 tons of powder and 17 tons of 65% dynamite. The area influenced by the charge was 400 metres long and 70 metres deep, and 150,000 tons of 2% copper ore was loosened. The cost was $31,000 U. S. currency, or P200,000 Chilean. To prevent poisonous gases finding their way into the adjoining workings, concrete walls were erected, while pipes and fans were provided.

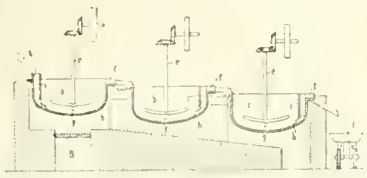
ROCK-DUST is used in preventing the starting of mine explosions, and in checking them after they have been initiated. This system seems to have had an advantage over those in which water is applied infrequently, in that more constant protection is afforded, as proved in coal mines near Pittsburg and in Colorado. Limestone dust, 75% passing 100-mesh, was used at Pittsburg. As coal-dust settles in the mine, rock-dust is blown in by a machine fitted on a flat-car running on the tracks of the mine-entry. This dust covers the coal dust, and is blown in at intervals. The U. S. Bureau of Mines has made considerable investigation of this subject.

THE WELDING of metals requires the use of a suitable flux to eliminate oxide between the faces of the two parts welded. Wrought iron is welded more easily than steel; the iron may be so hot that small globules fall off or it throws sparks in the forge, while steel will not stand so much heat without burning. The welding point of steel is generally judged to be when it seems wet or oily on the surface. Thermit welding, for heavy work, employs the heat generated by the chemical reaction in which aluminum takes oxygen from iron oxide; the welded part is stronger than originally by reason of a collar of new metal around the fracture. For welding wire hoops, or one metal to another, electric-resistance welding, employing alternating current is used. Gas-welding, including oxy-acetylene welding, uses gases under pressure which are ignited at the tip of a blow-pipe.

NEVADA is a Spanish word meaning snowy or white as snow, and the name of the State was derived from the Sierra Nevada. The State ranks sixth in size in the Union. Its length from north to south is 484 miles, its width 321 miles, and its area 109,821 square miles. The history of Nevada is chiefly the history of its mines. Since the discovery of the Comstock lode and other famous ore deposits, periods of activity and prosperity have alternated with periods of depression. Each discovery of high-grade ore in considerable quantity has been followed by rapid settlement in that locality and the establishment of one or more towns. In 1890-1893 a sharp decline in the price of silver initiated or accompanied a period of depression in Nevada's mining and general industrial prosperity. Silver is so important a resource of the State that to a large extent even now its prosperity depends on the market for that metal. Of late years, however, an increased production of gold, copper, and recently of antimony, platinum, tungsten, and zinc, has accompanied a gradual and, it is hoped, substantial industrial progress. Prosperous towns have grown-up, and agriculture and related pursuits are becoming firmly established.

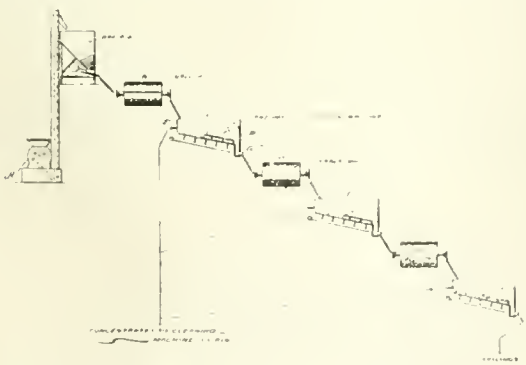
Recent Patents

1,169,270.—Apparatus for the Treatment of Ores. Erich Langguth, Neerpelt, Belgium. Original application filed Feb. 10, 1912, Serial No. 676,869. Divided and this application filed Oct. 4, 1912.



An apparatus for the treatment of an ore containing silver, comprising an integral vat provided with a curved side wall and a bottom wall merged into said side wall by a curved connection and being divided into a main compartment of circular cross section and a secondary compartment of crescent cross section by an integral diaphragm extending to the bottom of the vat and provided with an aperture near said vat bottom to establish communication between said compartments, the said diaphragm being of the same convexity as that of the side wall of said main compartment and being merged into said bottom wall by a curved connection of the same convexity as that of the curved connection first mentioned, whereby the entire inner surface of the diaphragm constitutes an unbroken continuation of the inner surface of said main compartment side and bottom walls, and the onter wall of said secondary compartment being curved so as to merge into the side and bottom walls of the main compartment.

1,176,441.—Process of Concentrating Ores. Ernest Gayford and George Crerar, Salt Lake City, Utah, assignors to Metals Recovery Company, Augusta, Me., a Corporation of Maine. Filed May 29, 1914.

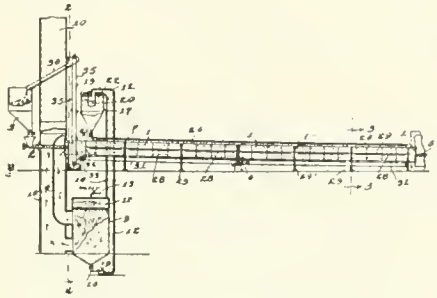


1. The process herein described, consisting, essentially, in progressively reducing, by successive stages, ore mixed with water and a frothable agent having a preferential affinity for metalliferous matter, aerating the mixture resulting from each reduction, and floating off the concentrates liberated at each reduction.

1,175,331.—Process of Concentrating Copper Values. Richard M. Atwater, Jr., Scarsdale, N. Y. Filed June 17, 1915.

1. The process of concentrating the copper values carried by copper tailings, which consists in treating said tailings in heaps with sufficient sulfuric acid to dissolve a substantial portion of their copper values; causing said values to be brought to the surface of said heaps by capillarity and to reassume the solid state by evaporation; and suitably removing from said heaps the concentrates thus produced, substantially as described.

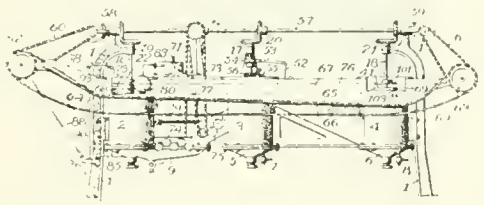
1,174,086.—Calcining Furnace. George Moore, Joplin, Mo. Filed Mar. 16, 1914.



1. In a calcining furnace, the combination with a furnace proper, of means for discharging hydrating waste solids in a sheet against the exterior of the furnace in quantities substantially only sufficient for requiring the waste heat of the furnace for drying.

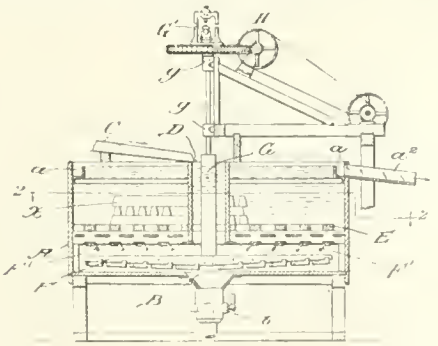
2. In a calcining furnace, the combination with a furnace proper, of a pipe extending along the furnace above the same, and having discharge apertures opening toward the furnace, and means for delivering hydrated solids to the pipe, the apertures in the pipe being proportioned to permit discharge of such solids on to the furnace in quantities substantially only requiring the waste heat of the furnace for drying.

1,175,616.—Ore Separator. George H. Davis, Worcester, Mass., assignor to Amerige-Davis Machine Company, Boston, Mass., a Corporation of Maine. Filed July 2, 1912.



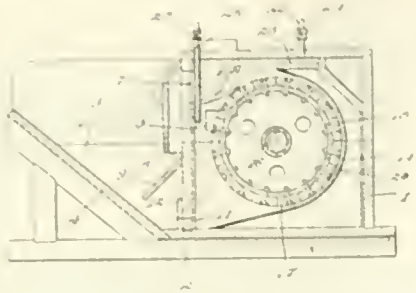
1. In an ore separator, the arrangement for conjoint action of an amalgamating section, a washing section and a screening section, an inclosed passage leading from the bottom of the amalgamating section to the screening section, with a portion of said passageway completely filled with mercury, means for agitating the mercury in said passage, and means for establishing a communication between the top of the amalgamating section and the top of the screening section below the water line.

1,177,109.—Precipitating Apparatus. Joseph Irving, Jr., Douglas, Ariz., assignor to The Dorr Cyanide Machinery Company, Denver, Colo. Filed Sept. 14, 1915.



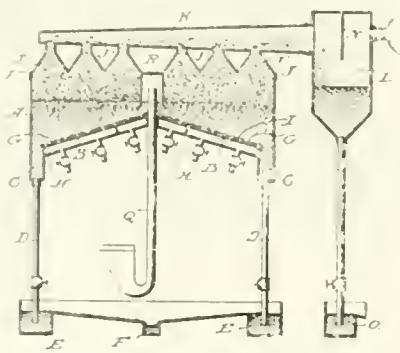
1. A precipitating apparatus comprising a vessel having a discharge opening at the bottom and a precipitant supporting reticulated frame through which the liquor passes, and slowly revolving scrapers or flights below the frame for moving the precipitate to the discharge opening and for spreading the incoming liquid beneath the supporting frame.

1,174,737.—Flotation Machine. Frederick R. Kollberg and Max Kraut, Bisbee, Ariz. Filed Aug. 2, 1915.



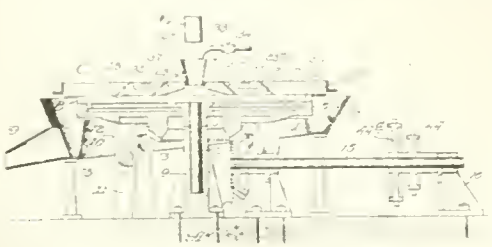
1. Apparatus of the class described comprising a spraying chamber, a frothing chamber, there being an outlet opening through which the spray created in said spraying chamber is adapted to pass to said frothing chamber; a fluid supply communicating with said spraying chamber; and means in said chamber for directing the fluid supplied to said spraying chamber toward said outlet opening, substantially as described.

1,176,428.—Flotation Separatory Apparatus and Process. John M. Callow, Salt Lake City, Utah, assignor to Metals Recovery Company, Augusta, Me., a Corporation of Maine. Filed Dec. 20, 1911. Serial No. 879,720. Renewed Jan. 21, 1916.



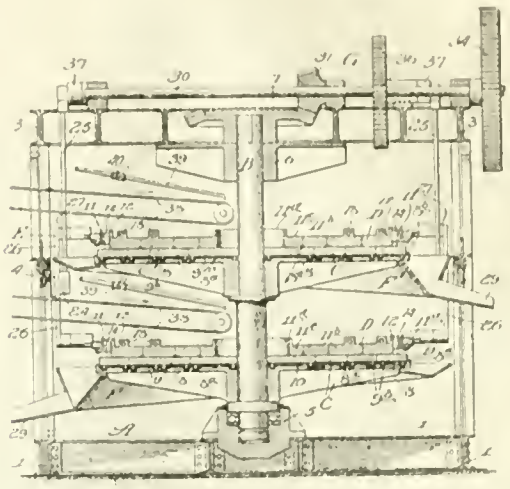
1. In flotation separatory apparatus, the combination with a tank adapted to contain comminuted ore and water and a frothable agent, said tank having a bottom restrictedly open to the atmosphere, and means for producing a suction in said tank to draw air through said bottom to generate bubbles and to destroy said bubbles and remove the mineral particles floated thereby.

1,175,782.—Concentrate Preparing Machine. Thomas J. Lovett, Chicago, Ill., assignor to Copper Process Company, Chicago, Ill., a Corporation of South Dakota. Filed Nov. 14, 1912. Serial No. 731,455. Renewed Jan. 20, 1916.



1. In an ore-reducing concentrate-preparing machine, the combination of a pair of gangue-pulverizing mineral-pelleting pressure members having substantially smooth extended area contact surfaces, one of said members being a floating member, means for relatively reciprocating and rotating said members, and means for feeding ore-pieces between said surfaces, said members so disposed, proportioned and cooperatively geared as to support and roll said ore-pieces between them, finely pulverize the gangue, pellet form the metals and discharge the materials with the concentrate thus prepared.

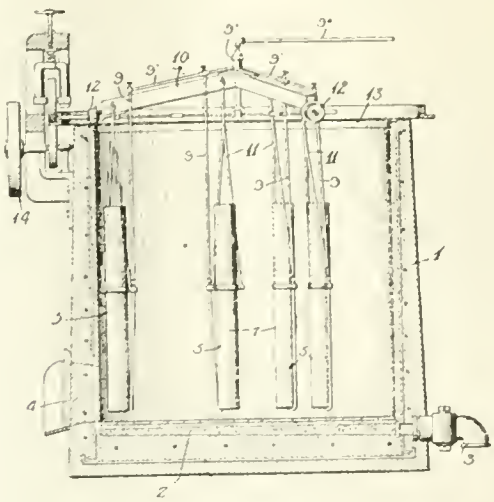
1,175,966.—Machine for Reducing Ores, &c. Thomas J. Lovett, Chicago, Ill., assignor to Copper Process Company, Chicago, Ill., a Corporation of South Dakota. Filed May 28, 1914.



1. In a machine of the character set forth, the combination of a plurality of suitably-spaced rotary members disposed one above the other, co-acting reciprocable pressure-members comprising floating-plates resting upon said rotary members, and means for reciprocating said second-named members in opposite direction.

2. In a machine of the character set forth, the combination of a frame, a vertical shaft journaled therein, rotary members supported by said shaft and fixed to rotate therewith, a reciprocable pressure and distributer-member co-acting with each rotary member and comprising floating-plates resting upon the rotary member, and means for shifting said reciprocable members with relation to the rotary members.

1,177,396.—Desulfurizing Method for Treating Refractory Ores. Edward Hale Dickie, Goldroad, Ariz. Filed Jan. 25, 1915.



The method of treating refractory ores consisting in mixing the finely ground ore with a solution of caustic soda and potassium acetate, agitating the mixture in the presence of a metallic value precipitant, and finally removing the solution.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

LEADVILLE, COLORADO

Labor and Wages at Mines and the Smelter.—Sale of the Robert Emmet Mine.—The Zinc Smelter.

At a meeting of mine managers and operators held here on April 12, all men employed in Leadville mines were voted a 10% increase in wages, to take effect from April 1. The increase is based on the price of spelter, and will remain in force while that metal is quoted at 10c. per pound or more. It is conservatively estimated that 1500 men will receive the benefit of the advance. For years Leadville has been a $3 centre, miners, shovelers, and trammers all receiving the same pay. This wage has been maintained during periods of depression as well as times of prosperity, with apparent satisfaction to employers and employees alike. The recent advance in the metal markets brought about a change in conditions which made it necessary to adjust wages. The great copper districts of Nevada, Utah, Arizona, and Montana commenced a sliding wage-scale, greatly increasing the pay, and miners from all parts of the country flocked to these places in search of employment, with the result that many other mining areas were left short-handed. Leadville experienced a noticeable lack of efficient men, and conditions were gradually growing worse when it was decided to increase wages 10% all around, although many of the companies that accepted the advance were in no better condition than they were years ago. At present Leadville is a heavy producer of zinc, the greater part of the district's tonnage being that kind of ore. The majority of the men employed in the district are working in zinc-producing mines, which for some time have been making fine profits due to high prices for the metal. There are, however, many properties here that are not producing any zinc ore. Copper, lead, silver, and gold ores are mined extensively. The first two metals command high prices, while silver is steadily advancing, so that companies producing these ores can easily afford to raise wages. Gold properties are the exception, however, and for the first time we find these following, instead of leading the other branches of the mining industry. The companies represented at the meeting are the Western Mining Co., Down Town Mines Co., Star Consolidated Mining Co., United States S. R. M. & E. Co., New Monarch Mining Co., Yak Mining, Milling & Tunnel Co., Iron Silver Mining Co., Ibex Mining Co. and lessees, Garbutt lease, Louisville mine, Dinero Mining Co., George E. Cramer & Co., Porter lease, Mikado mine, Highland group, Burton leases, Robert Emmet, Denver City, Fortune, Luema Mining Co., and the Bowden leases.

Following the recent strike at the Arkansas Valley smelter of the A. S. & R. Co., the company voluntarily increased wages in the plant, taking effect on April 1. The announcement of the advance as posted in the various departments is as follows: "Beginning April 1, 1916, and continuing while there is a sustained price for lead in New York of 6c. or over per pound for the preceding month, the following additions to the present daily wage scale will be paid: on wages up to and including $2.25 per day, 15c. per day; over $2.25, up to and including $3 per day, 20c. per day; and over $3 per day, 25c. per day." The advance in wages will affect 800 men employed at the plant, which is now operating at full capacity.

However, in spite of the fact that the mines and smelter here have voluntarily raised wages, there is much discontent among the men, especially the miners, who consider that the increase is not as great as it should be under existing conditions. They argue that with the present strong metal market, mine and smelter operators are in a position to pay labor a higher scale of wages. The miners want $3.50 a day, and $4 for machine-men. The local branch of the Miners' Union is holding open meeting for the discussion of the wage question, but as yet nothing definite has been decided upon.

The purchase of the Small Hopes-Boreel property by the Empire Zinc Co. for a sum exceeding $500,000 is one of the largest mining transactions closed here for several months, and is the cause of renewed activity at other mines in that section. The Small Hopes company, operating through the Robert Emmet shaft, has opened one of the largest bodies of zinc sulphide ore that has ever been found in the district. During the past three or four months the property has been shipping from $40,000 to $50,000 worth of ore each month. In addition to the zinc, several shoots of lead have been uncovered, all above water-level at the 600-ft. level. When the Robert Emmet was one of the big mines of the district, a large pumping plant drained the property to the 1300-ft. level. Huge deposits of sulphide ores were uncovered in the lower workings, said to be larger than those now being worked above. Until recently, the ore in the Emmet was not commercially valuable, and the property has been allowed to fill up with water to the natural level. High prices for zinc and lead ores have brought about a change in conditions that make the Emmet one of the richest mines in the district, and the price paid for the ground is stated to be very reasonable. By the transaction, the Empire Zinc Co. secured title to the Robert Emmet, Result, Forest City, Gonabrod, and Ranchero claims in Stray Horse gulch. This tract is surrounded by such mines at the Wolftone, the largest zinc producer in the State; the El Paso, formerly one of the richest silver mines here; the Greenback, said to be worth $1,000,000; and the Ponsardin, now shipping $20,000 of zinc sulphide per month. Mining men who are familiar with the Emmet and other claims in the purchase, state that although the orebodies opened in the Emmet are the greatest ever developed here, those known to exist in the Gonabrod are even greater. There are millions of tons of ore opened, and when the Empire people take active charge, a large output will be maintained. The Small Hopes company will continue to operate the property for 90 days, until its contracts for ore shipments are canceled. During that time it is estimated that $150,000 of ore will be extracted.

Extensive pumping operations are being planned for the territory surrounding the Emmet. George O. Argall and associates have formed a $10,000,000 company for draining east Carbonate hill, and have secured leases and options on the R. A. M., Pyrenees, Mikados, Cyclops, and other adjoining ground. This project will unwater a large area of rich territory and will lower the water in the ground purchased by the Empire Zinc Co. It is also reported from authoritative sources that the Western Mining Co. is preparing to unwater its holdings of Carbonate hill, including the Wolftone, Adams, and Mahala. The Wolftone is now 1300 ft. deep, and pumping will be done through this shaft. This undertaking will also affect the Emmet ground, and it is thought that the Empire Zinc, instead of installing a pumping plant at the Emmet, will pay these other companies draining royalties.

The Western Zinc Oxide Co. is now preparing to enlarge the

smelting plant for the manufacture of zinc oxide, which has been in operation here for two years. At present, the plant has a capacity of 50 tons per day, but owing to various causes has never reached beyond 35 tons. Another block of four furnaces is to be added as soon as men can be secured to carry on construction work. This will give the plant a capacity of 75 tons per day. James A. Whittington, formerly in charge of a large plant at Depue, Illinois, has been secured to direct the building and to manage the plant. The Midland Chemical Co. of Chicago, manufacturer of lithopone, has purchased a 25% interest in the local concern, and has contracted for the output of the plant. The process for the manufacture of zinc oxide used by the Western company has proved a success. During the two years' operation the plant has been able to treat a quantity of low-grade carbonate ore that could not otherwise be marketed. It has turned out on an average 50 tons per week of oxide that contains from 75 to 90% zinc. This product has commanded a great price, and at present is much in demand. Following the addition of another block of furnaces, a roasting plant will be installed for treating zinc sulphide.

MEXICO CITY, MEXICO

NEW MINING LAW.—GENERAL CONDITIONS.—PACHUCA AND EL ORO.—MONEY.

A decree is soon to be issued by Carranza making effective the new mining law. An important feature is said to be the discouragement of large holdings of undeveloped ground, compared with the present law which does not limit the number of claims that may be 'denounced.' The new taxes will be based on minimum and maximum precious-metal holdings. The small company, with nine or less claims, is to pay yearly P6 Mexican gold for each claim; from 10 to 50 claims the tax is P12; from 50 to 100 claims P18; and all over 100 claims P24 each. More liberal terms are offered to base metal properties. The export duty on bullion is raised from 7½ to 10%.

Mail from the United States is coming through to Mexico City in about 6 days. Traveling by rail is somewhat uncomfortable, due to difficulty in getting meals and crowded trains. In spite of the poverty-stricken reports there are many people moving about. As most of the freight-cars have been destroyed or are being used as traveling homes for soldiers and their families, it is difficult to get in supplies to mines or ship concentrate. If the latter went out of Mexico like bullion, more speed would probably be shown, as there is an export duty payable in gold. When goods enter the country, duty is paid and companies take chances in getting them forwarded. Graft is rampant along the railroad. At Pachuca the Real del Monte company has over $1,000,000 of concentrate on hand. It secured some locomotives and cars to haul the product to the smelter, but only one train a month was possible. It seems as if there was only one crop grown around Mexico City, namely, *maguey*, from which *pulque*, *mescal*, and other fiery liquors are made. The product is forbidden in the City, but there must be a large demand for it. The rate of exchange has been 50 to 1, but at present P25 are only worth $1 U. S. currency. All the present 'money' is to be withdrawn and replaced by new paper, which the authorities claim will be more difficult to counterfeit.

Regarding conditions at El Oro it might be said that everything has been quiet for a long time, but things are looking so good today (April 18) that it seems at least two of the companies here will be operating before the end of another week. There has been no trouble with labor here of late, but when work is started it is likely that the mines will be shorthanded, as the majority of the *gente* have gone to their *tierras* to look after planting and growing crops.

Carranza entered Mexico City in triumph on April 17, and had the pleasure of riding through the numerous triumphal arches that have been under construction for eight months.

GUADALAJARA, MEXICO

MONEY, MINING, AND CONDITIONS GENERALLY

From Mexican refugees whom I met in New York I gathered that the Mexican peso had not declined as rapidly in purchasing power as it had in exchange value, and I find this to be the case. Take railroad fares as an extreme instance: from Vera Cruz to Mexico City a ticket costs 28 pesos, from Mexico City to Guadalajara it costs 37 pesos. The Mexican peso at the present rate of exchange is worth slightly less than 4 cents in gold, so that the trip from Vera Cruz to Guadalajara requires $2.60 gold. An additional $1.50 gold pays the fare to Manzanillo. A ride across the continent therefore will cost about $4.10. The journey from the American border to the Guatamalan frontier costs about $6.50, I have been told. As a consequence of these low rates the cars are crowded to a point where they resemble subway trains during the rush-hour. This side of Queretaro a peon woman, as a result of this crowding, fell off the roof of one of the box-cars ahead of the car I was in. We were going at a pretty fair clip and didn't stop to pick her up. Upon arriving at Guadalajara Mr. M., the treasurer of a local company and a prominent citizen, his wife, and myself climbed out of our car-window as the easiest way of leaving the train. It is hard to imagine one of the socially prominent matrons in a city of 125,000 people in the United States climbing through a car-window upon arriving at her native city, especially if she were verging on portliness.

When I arrived at Guadalajara the street-cars were charging ½ cent gold for a ride first-class. I am paying 35 cents gold for room and board at one of the best hotels here. The landlord's monthly rental, which is 600 pesos, has shrunk from $300 gold to $24. Cigars cost only 2.4 cents each and an extension of my visitor's card at the club cost 8 cents for two weeks. The place is a veritable paradise for an impoverished and obscure engineer like myself.

The Mexican government has virtually prohibited dealings in exchange and also prohibits the transfer of real estate from Mexicans to foreigners. This last prohibition is, I believe, in a measure justified as real-estate values have dwindled to a point far below their pre-revolutionary figure. In some instances improved property has sold for as little as a fifth of what it would have brought before the revolution.

The *bil-im-bique* or paper peso is a *forzoso* currency, which fact has enabled debtors who incurred obligations when exchange was 2:1 to discharge their obligations at four cents on the dollar. A ranch near here sold for $1,000,000 during the pre-revolutionary epoch and payments were distributed over a long term of years. The buyers have recently met their notes with 4-cent pesos.

Difficulty in securing exchange has produced some curious effects. Merchants realizing on their stocks are unable to replenish them. They are granted no credit in the United States and freight-cars in Mexico being scarce, they must be personally conducted and cannot be secured unless *gratificaciones* amounting to several hundred dollars gold per car are paid to the proper parties. Merchants are not renewing stocks, and being unable to secure exchange are investing their accumulating paper money in real estate or in anything that holds promise of ultimate, tangible, pecuniary return. Promoters have taken clever advantage of the frantic psychology of a rapidly falling exchange and have organized all manner of mushroom oil companies. In their prospectuses they state that a peso in paper invested today will be worth a peso in silver tomorrow. As to mining, it is impossible except in the older and established camps. In Jalisco, Cinco Minas and El Amparo are the only properties operating.

At this juncture a loan would, I believe, save Mexico; but with a steadily depreciating currency and the printing presses working over-time I can't see what is to hold the army together and prevent it from disintegrating into brigandage. At present there is, however, a slowly crystallizing military autocracy, judging by recent work by Gonzales and Dieguez.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

The U. S. Geological Survey has issued Water-Supply Paper 372, 'A Water-Power Reconnaissance in South-Central Alaska,' by C. E. Ellsworth and R. W. Davenport, with a section on south-eastern Alaska by J. C. Hoyt. The publication covers 173 pages, including illustrations and maps. The areas discussed are Controller bay, Copper river, Prince William Sound, Kenai peninsula, Willow creek, and others.

Fairbanks

It is estimated by local authorities that the Fairbanks region will produce over $4,000,000 this season, an increase of $500,000. The Tolovana district may yield $650,000. Antimony, tin, and tungsten ores will help swell the returns.

Juneau

A suit has been started at Juneau over 11 claims on Sheep Creek mountain between the Alaska Gold-Belt and Alaska Taku companies. Both claim the property. At a depth of 2500 ft. the Gould and Curry vein of the Gold-Belt company has been cut by the diamond-drill. The hole is in 1575 ft. horizontally, which is claimed to be a record for such a flat hole. The rods are greased continually. There is danger of water forced through the rods to the bit being frozen. The work was done by Lynch brothers, in charge of A. B. Dodd, the superintendent.

ARIZONA

Gypsum is discussed in Bulletin 19 of the State Bureau of Mines, by Frank L. Culin, Jr. The best deposits in Arizona are in Navajo, Cochise, Pinal, and Pima counties; those in the Santa Rita mountains are of considerable extent.

Mohave County

At 500 ft. depth in the Gold Ore mine, at Gold Road, the shoot is 200 ft. long and 6 ft. wide. A stope above this level has given high assays in gold and silver. Of the 60 tons broken each day, 25 tons is sent to the mill, on account of shortage of trucks.

At 110 ft. from the shaft, on the 485-ft. level, the Big Jim has cut the shoot opened above. So far, it is 26 ft. wide, assaying $12 per ton. On the 400-ft. level the vein was 46 ft. wide of $7.44 ore.

At the Tennessee mine at Chloride steam has superseded gasoline. The daily output of ore sent to the Needles mill and smelter is 300 tons.

Development at 665 ft. in the United Eastern is highly satisfactory. The north drift is out 200 ft. The vein is 40 ft. wide, assaying $21 per ton. In other places the vein is wide and of high value. The new three-compartment shaft is being sunk on one shift. Good progress is reported on grading for the mill.

Yavapai County

This county's mines are being operated at high pressure. In the last week of March, 114 carloads of ore and 11 carloads of copper bullion were dispatched.

The Crown King district is growing busier. Three mills are working, while the fourth soon will be. The last will treat tailing by flotation.

Rich silver ore, containing some copper, has been opened for 50 ft. in length and 4 ft. in width in the Tuscumbia mine, in the Bradshaw mountains. The ore is similar to that of Tonopah, Nevada.

The quicksilver claims in Copper Basin of Ross, McNary, and Hall are under option to Bowler and Pell of New York. A large quantity of good ore is said to be ready for the large reduction plant proposed.

CALIFORNIA

Considerable activity is reported from the districts containing chrome-iron ore deposits. Near Stony creek in Amador county a large quantity is to be mined to fulfill a contract. Fifteen auto-trucks are to carry ore from Dickey and Diesbach's mine at Woodleaf in Butte county. The first shipment has been made from Pentz. San Franciscans are developing the Negro Hill deposits in Sacramento county. From Lowrey, in Tehama county, the Noble Electric Steel Co. has let a contract to haul ore to Red Bluff, then on to its smelter by rail. Near Wildwood, in Trinity county, a large deposit is being investigated.

Amador County

Some good ore has been opened at 2800 ft. in the Central Eureka. Twenty of the forty stamps are dropping.

Steady progress is reported from the South Eureka, where 175 men are kept busy. The company is unwatering the Oneida mine nearby. A dividend of $20,990 was paid last week.

The Argonaut and Bunker Hill companies have distributed $15,000 and $5000, respectively.

Calaveras County

(Special Correspondence.)—T. M. Lane is now arranging with Collins brothers of Jenny Lind to allow them to commence operations, as lessees, on the Plymouth Rock or Jenny Lind mine. The property was last worked, in a small way five years ago. It is now intended to install a steam hoist. The ore, which contains copper, gold, and silver, will be hand sorted and shipped to a smelter for treatment. Mrs. Charles D. Lane is owner.

The Nugget Queen or Egan mine has been bonded by L. Estelle Sibbald of Denver, Colorado. The shaft has been unwatered and an examination of the underground workings has been made by Fred G. King of San Francisco, who has left for that city with samples. After his report is received a definite plan of operations will be decided on. The property is supposed to have an extension of the Hodson vein, lying in a westerly direction from there.

Copperopolis, April 18.

It is reported that Sacramento people are to dredge old hydraulic tailing in Chili gulch near Mokelumne Hill.

Inyo County

Tungsten claims 8 miles west of Bishop are to be actively worked this summer. The property of L. E. Stevens and F. M. Townsend is said to contain 50,000 tons of ore available by quarrying. A 200-ton mill is contemplated.

Plumas County

At the Engels copper mine near Taylorsville an adit has been started to open the vein at a depth of 750 ft.

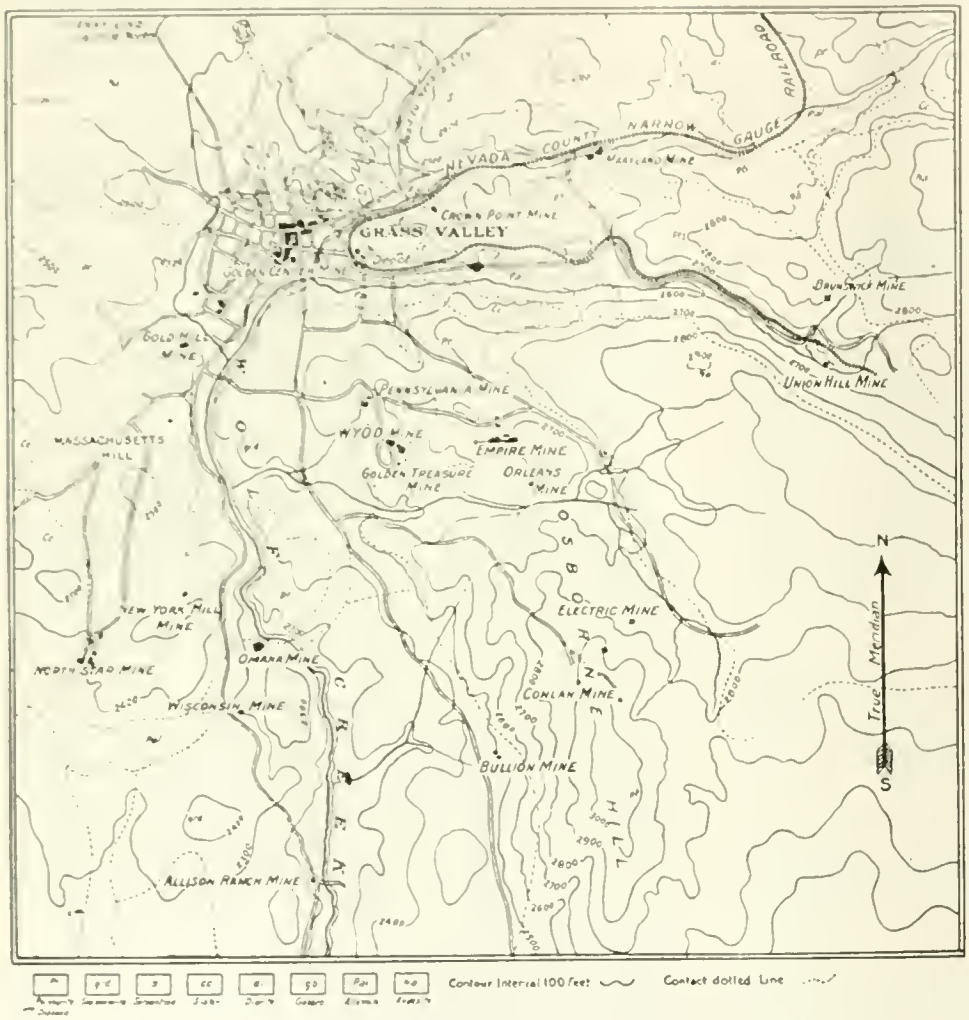
A syndicate is being organized by G. O. Dowden at Portola to operate an option on eight copper claims between the Engels and Walker mines.

Shasta County

The Herbault property of 126 acres on Cottonwood creek, near Gas Point, has been bonded to J. Brower and C. H. Mitchell of Alaska, who will construct a dredge at an early date. At Heroult the Noble Electric Steel Co. has started one electric furnace producing ferromanganese.

Nevada County

The Grass Valley Consolidated Gold Mines, a new company of 500,000 $1 shares, composed of Golden Center company's directors and others, has purchased the Allison Ranch mine, south of Grass Valley. The property has been closed since



MAP OF THE GRASS VALLEY DISTRICT, CALIFORNIA. (After the U. S. G. S.)

July 1902. It will be unwatered and re-opened in charge of C. A. Brockington and a complete plant is to be erected.

The Pennsylvania Consolidated Mining Co. distributed a final dividend of $5.775 per share on 51,476 shares last week, being the last payment due by the Empire Mines Co., which purchased the property for $500,000. The Pennsylvania company is to be dissolved at an early date.

The Empire company during the past few months has acquired 430 acres of ground, including the Town Talk placer mine, and the Bogue and Manian ranches.

It is said that the Union Hill mine may come under the control of the company, which has an option on the South Idaho mine.

Tuolumne County

(Special Correspondence.)—It is understood that the Alabama and Crystalline mines, situated north of the Harvard, are to be re-opened soon. The properties have been taken over under bond by C. S. Young, for many years identified with oil in southern California. The Alabama has a 300-ft. shaft and an adit of considerable length, the Crystalline has been opened to 600 ft., and according to reliable information has produced $250,000.

The shafts on what is known as the Ranch mine are being unwatered to lessen the danger to the miners employed in the Springfield Tunnel & Development Co.'s long adit, now almost up to the old shafts. The adit, which is to be 6000 ft. long, already exceeds 3000 ft. The Ranch mine property was acquired by the Springfield company several years ago. The company has cut one of the subterranean channels that traverse its property, and the gravel washed gave encouraging gold returns, but the main channel, from which the best results are expected, will not be reached for some time yet.

A prospect on the Burns ranch, near Soulsbyville, that gives promise of developing into a mine of merit, is being worked by Benjamin Addis and others. A shaft has been sunk and at a depth of 75 ft. a drift driven, revealing some high-grade ore.

The Hope mine, near Sonora, is employing 14 men. It is a pocket-milling vein and has yielded well during the past year. Two or three pockets of generous size were taken out, besides a large tonnage of good milling ore.

Sonora, April 14.

COLORADO

The public sale of the property of the U. S. Reduction & Refining Co. at Colorado Springs was postponed to April 25. The Court has fixed a minimum of $250,000 for the following: All right, title, and interest of the defendant company in the Standard plant, near Colorado City; the Union plant near Florence, in Fremont county; the Metallic cyanide plant at Cyanide, in Fremont county; the interests of the company in the Cripple Creek Sampling & Ore Co.; the property situated in the Cripple Creek mining district, Teller county; all interest in the plant and site of the United States Smelting Co. near Canon City in Fremont county; the National plant near Florence, in Fremont county; the National Sampler site near Cripple Creek; all mining claims owned by the defendant company in Summit county; the Brush Hollow ranch of 200 acres in Fremont county, together with all water rights, reservoirs, pipe-lines, franchises, contracts, etc.

Clear Creek County

(Special Correspondence.)—The French Flag mine in Gilson gulch is to be equipped with a 50-ton mill. The manager, C. H. Ripley, states that ore treatment will commence within 60 days.

The Argo Leasing Co., operating the Doctor Town mine in the Daily district, will construct a 50-ton concentrating mill early this summer. In the mine is a shoot of lead, zinc, and iron ore that is 1000 ft. long. A. Hanson of Empire is manager.

Every mill in the Idaho Springs district is operating full time: The Newton is treating 80 tons daily; the Jackson, 50;

the Hudson, 75; the Argo, 150; the Stanley 25, and the Ronaldson, 25 tons. Shippers are experiencing difficulty in having their product treated.

Contractors on the Big Five adit are advancing it at the rate of 150 ft. per month. The heading is now nearing the Gilpin County line.

Idaho Springs, April 10.

Ouray County

Work has been resumed at the Mountain Top and Wanakah mines.——Rich tungsten ore has been opened in the Dunmore claim, four miles from Ouray.——The Adams tungsten mine, said to be one of the best in the county, is tied-up in a law-suit.

Summit County

Gold worth $7000, the first of the 1916 dredging season, was shipped from Breckenridge by the Tonopah Placers Co. two weeks ago.

Teller County

The flotation plant at Stratton's Independence mill is doing good work. In March 14,900 tons of $2.63 ore was treated. The capacity will be increased gradually to 1000 tons per day.

IDAHO

Lemhi County

(Special Correspondence.)—At the Queen mine, 8 miles north of Salmon, work has been resumed at the mine and mill with 20 men.——R. E. Wickham and others who have been blocking-out ore in high-grade gold claims 10 miles north-east of Salmon are erecting a stamp-mill.——The Musgrove property near Forney is being sampled; it probably will be sold. William J. Hoffman has just finished delivering 18,000 ft. of lumber for the Bohanan Dredging & Hydraulic Co.——As the season advances several mine-owners contemplate resumption of operations, which were suspended on account of deep snow and bad roads.

Salmon, April 5.

Shoshone County (Coeur d'Alene)

With a capital of 5000 $10 shares, the Idaho Railroad Co. has been incorporated by Herman J. Rossi, W. H. Herrick, and C. F. O. Merriam of Wallace, and W. W. Papesh of Kellogg, to construct a railway up Pine creek from Pine Creek station, on the O.-W. R & N. company's Wallace branch, to the Constitution mine, a distance of 10 miles, and probably extensions into surrounding territory at a later date. The line will provide transportation for a number of promising mines in the Pine Creek region, including the Highland-Surprise, Naboh, Little Pittsburg, Constitution, Douglas, Amy-Matchless, Coeur d'Alene Antimony, and several others, and undoubtedly will encourage development of many prospects that now are practically dormant. The new company is understood to have secured right-of-way concessions for practically the entire distance, and a preliminary survey has been made.

During the period ended April 2, 1916, the Highland-Surprise Consolidated Mining Co. in the Pine Creek district received $44,123 from the sale of zinc and lead concentrates ($27,214) and treasury shares, etc. The cash balance is $4820; also ore in bins worth $16,200. A good tonnage of ore is broken in the stopes. The mill will resume when roads are in good order for hauling.

During 1915 the Success Mining Co., in the Nine-Mile district, made a profit of $898,936, and paid $555,000 in dividends, against having a deficit of $92,825 at the end of the previous year. The income was $1,255,802. Development covered 1375 ft., and other work. Reserves are sufficient to supply the mill for 18 months with zinc ore.

According to the report of J. F. McCarthy of the National Copper Mining Co. of Mullan for 1915, there is enough ore above the 1200-ft. level to supply the mill for two years. When this property was equipped with mill, electric railway, etc., the engineer on whose recommendation the improvements were made, estimated 545,000 tons as available above the 1000-ft. level. When the mill was equipped and in operation, an unexpected barren shoot was found in the mine, which reduced this tonnage, according to the same engineer, to 170,000 tons. The mill was operated in April and May 1914, and the disappointment in mine developments together with the low price of the metals made a suspension of operations seem wise. During this suspension a winze was sunk 200 ft. to the 1200-ft. level. There was an opinion held by those familiar with the property, that the hanging-wall side of the vein contained better ore than any other portion. There was first milled 1200 tons from a drift on the hanging wall of the 1200-ft. level; then 2700 tons from the 1000-ft. level stopes. These tests proved that the ore is disseminated throughout the vein and that there is no segregation of value in either wall. During January was milled 4243 tons of ore from all parts of the mine. This was a stormy, cold month. Daily automatic samples were taken, giving 0.83% copper and 1.99 oz. silver. The mill produced 105 tons of concentrate, containing 22% copper, 52 oz. silver, and 0.05 oz. gold, worth $10,815 net. This will show a loss of approximately $1300 above operating expenses. Transport of ore from mine to mill cost 24c. per ton. It is recommended to work the mill two shifts; purchase more mill supplies, another locomotive, and 20 ore-cars, costing $11,000; and sink to 1400 ft. If development is satisfactory an 8000-ft. adit would have to be driven, costing $175,000.

KANSAS

Cherokee County

New zinc smelters are being constructed at Weir and Fort Smith. Galena people are largely interested.

MICHIGAN

The Copper Country

The official figures of the Calumet & Hecla and subsidiaries' output in March are as under, in pounds:

Mine	March	Three months
Ahmeek	2,175,930	4,951,270
Allouez	1,028,054	2,332,294
Calumet & Hecla	6,234,418	18,364,404
Centennial	252,428	563,109
Isle Royale	1,112,206	2,817,911
La Salle	108,321	343,783
Osceola	1,633,711	4,661,033
Superior	296,380	755,875
Tamarack	594,991	1,751,406
White Pine	345,641	1,036,830

MISSOURI

Jasper County

Owing to the large quantity of ore shipped and high prices for same the Missouri-Kansas-Oklahoma region's output in the week ended April 15 was a record, namely, $1,433,827. A year ago the value was $369,937. The yield was 11,495 tons of blende, 997 tons of calamine, and 1207 tons of lead, averaging $107, $81, and $100 per ton respectively. For 15 weeks the total is $12,833,717.

MONTANA

Of the total of 440 miles of railroad to be electrically operated, the Chicago, Milwaukee, and St. Paul has 226 miles worked by electric locomotives, between Harlowton and Deer Lodge. The remainder of the distance, Deer Lodge to Avery, Idaho, is being constructed, that is, fitted with electrical apparatus. The new system is entirely satisfactory, with lower costs than steam, and larger loads.

Broadwater County

The Black Friday gold claims, credited with several hundred thousand dollars worth of high-grade ore shipments, two miles

southwest of the famous Keating company's properties at Radersburg have been taken over for a reported price of $250,000 by E. N. Breitung & Co. of New York. The deal was negotiated through Sidney Norman of Spokane, and the purchasers were represented by Harry B. Barling, the firm's chief consulting engineer. The mine has been opened to 700 ft. depth. The 50-ton mill is to be enlarged.

Lewis and Clark County

Eight properties, totaling 180 acres, have been consolidated in the Marysville district, and will be operated by the Marysville Gold Mining Co. The arrangement was perfected by L. S. Ropes, O. M. Lanstrum, and M. L. Hewett. Adjacent to the ground are the Drumlummon, St. Louis, Belmont, Bald Mountain, Gloster, Empire, Bell Boy, Penobscott, Shannon, and Bald Butte mines, all well known.

Lincoln County

The Snowstorm Mining Co., which operated the Snowstorm copper mine at Larson, Idaho, has been acquired by the Snowstorm Mines Consolidated, to work the Banner and Bangle claims near Troy. A 250-ton mill will be erected a mile from Troy, also one mile of standard and six miles of 36-in. gauge railways, and a 1500-hp. hydro-electric power-plant, the whole to cost $500,000. Over 400 men are to be employed. The mine, in charge of R. E. Walters, has a long shoot of lead-zinc ore.

Silverbow County (Butte)

In the second first-aid contest between the Anaconda company's mines held once a week, the winners were the Original, Anaconda, and Poulin teams.

Native copper has been found at 600 ft. in the Tropic mine of the Anaconda company.

NEVADA

Esmeralda County

Treating dump ore the Nevada Metal Extraction Co.'s flotation plant at Goldfield is recovering well over 90% of the gold and copper. The daily tonnage of $6 ore is up to 150, and costs will be around $2.25 per ton. The Florence dump contains over 50,000 tons. Janney machines are used. Concentrate is worth $70 per ton.

Humboldt County

Twenty-two miles from Lovelock are the Ragged Top tungsten claims of L. E. Beeson, Makedon brothers, and E. Henning, which have been optioned for a large sum to Eastern people. The scheelite contains from 1.5 to 3.5% tungsten.

Lyon County

According to the annual report of the Mason Valley Mines Co. its smelter at Thompson will be started when a steady supply of ore is assured.

Mineral County

To operate the Golden Pen and other claims at Rand, Jesse Knight of Utah will organize the Gold Pen Consolidated Mining Co. Rich ore has been recently extracted.

Nye County

Two miles south of Belmont are the tungsten claims of Humphrey brothers, P. O. Harris, and M. J. Keely, which have been sold to A. B. Call of Pasadena for $100,000 on terms.

In the vicinity of Round Mountain there are 60 men engaged in mining tungsten ore. The hills are full of prospectors.

White Pine County

To haul tungsten ore from the Independent mine to Ely, a distance of 26 miles, auto-trucks are to be used.

Tungsten placers are reported to be of importance in the Snake range, and sluicing has already commenced where water is available.

NEW MEXICO

Grant County

Last week the new mill of the Burro Mountain Copper Co. commenced work, two weeks ahead of the scheduled date.

OREGON

Baker County

The holdings of the Cougar Mining & Milling Co., 17 miles from Sumpter, one of the oldest developed properties in the district, have been taken over under an 18-month lease and bond for $300,000 (on terms) by the United Gold Mining Co., recently organized by Spokane men. The new corporation is capitalized at 1,000,000 shares at $1 each, of which 400,000 are issued. The officers are Arthur B. Lee president, C. F. Elkenbary vice-president, and Chester C. Robbins secretary-treasurer, who are prominent in Spokane business and professional circles. The largest shareholders in the Cougar company are D. A. Evans and John W. Larkin of Spokane. E. C. Brain of Helena, Montana, is general manager. Development has been done to a depth of 500 ft., and ore exposed is worth $750,000. A 200-ton mill is in good order, but tube-mills and a cyanide plant are necessary.

SOUTH DAKOTA

Lawrence County

Disagreement among the Rattlesnake Jack owners has resulted in a shut-down. In February 1800 tons of ore yielded gold worth $9800, with a profit of $5200.

UTAH

Juab County

Iron ore amounting to over 100 tons daily is being mined at the Dragon Consolidated and sent to the International smelter in Tooele county. This ore occurs between the 400 and 800-ft. levels. The mine is also producing lead-silver ore for the Knight-Dern mill at Tintic.

A dividend of $1 per share is to be paid by the Centennial-Eureka company, a subsidiary of the U. S. S. R. & M. Co., the first since September 1913.

Salt Lake County

The Tar Baby's adit is in 2130 ft., a vertical depth of 1200 ft. The country is mineralized. The limestone-black rock formation contact is expected to be cut at an early date.

The Michigan-Utah company will have 100 men at work within 60 days. The Triangle Leasing Co. is extracting 50 tons daily.

The Alta Tunnel & Transportation Co.'s adit is in 1950 ft., about half way, with a daily progress of 5 ft. Eventually the adit will enter numbers of mines and solve the ore-transport problem.

Summit County

On May 15 the Big Four Exploration Co., which is treating old tailing at Atkinson, 7 miles from Park City, will pay 5c. a share, equal to $20,000. The 250-ton plant is being enlarged to 750 tons, by adding 27 Wilfley, Overstrom, and Deister tables. Steam-shovels are to dig the tailing-dumps.

From royalties, ore and silver sales, etc., the Ontario Silver Mining Co.'s revenue last year was $72,683. Cash assets amount to $312,574, an increase of $12,000. From the 900-ft. level to the surface the mine is under lease, employing 70 men. The shaft has been unwatered to 1700 ft., and a centrifugal pump installed.

WASHINGTON

Stevens County

A third lead furnace of 300-ton capacity is being installed at the Northport smelter. The other two are reducing Hercules and Tamarack & Custer ores.

In northern Washington, particularly in this county, highway officials are assisting the mining companies to finance construction of connecting links with the State roads, and are offering every inducement within their power to encourage development of the mineral resources of the region. For the first time in the history of the State, public officers are beginning to recognize mining as an industry worthy of being fos-

tered, and the outlook in this regard is particularly promising, according to the Northwestern Mining News Service of Spokane.

The Norman Mines Co., which is operating the Great Western and Last Chance mines near Northport under lease and bond, has contracted 3000 tons of zinc carbonate (29% metal) ore to the Kusa Spelter Co., Dewar, Oklahoma, delivery to be made at the rate of 500 to 1000 tons monthly.

WISCONSIN

There is a shortage of shovelers in the southern zinc centres of the State. Shovelers and can men are earning $2.75 to $3 per shift. Fully 500 more men could easily find employment, and operators claim this shortage is responsible for about one-third decreased output.

CANADA

British Columbia

On April 10 the Standard Silver-Lead company paid 2½c. per share, or $50,000, making $200,000 for 1916 and $2,000,000 to date. The mine is opened by seven adits, with No. 8 being driven. Crude ore shipments average 50% lead and 85% silver, and milling ore 10% lead, 18 oz. silver, and 10% zinc.

The Hope district is fairly quiet at present, but a revival is expected this season. Some rich gold ore has been sacked by M. Merrick for shipment to the Selby smelter. There is a large area of gold-bearing country unprospected, extending from Ruby creek in the state of Washington through Lillooet and Bridge river to the Chilcooten country. It is not easy ground to prospect. Capital is wanted. A few placer miners are working on the Coquahalla river.

Ontario

A steel head-frame at the Hollinger's Acme shaft is almost complete. The large hoist will not be ready at the manufacturers for 10 weeks. Considerable work is being done at a depth of 1250 feet.

At the McIntyre mine the 1000-ft. level station is finished. A 50-ton Callow flotation plant is to be built at the Sable River Mining Co.'s copper mine, between Sudbury and the Soo. The mineral is chalcopyrite.

A 50-ton Callow flotation plant is to be erected by the Penn-Canadian company.

During March 144 tons of high and 6698 tons of low grade ores at the Nipissing yielded $169,999. Including custom ore the refinery produced 551,921 oz. silver. A winze sunk 150 ft. below the 490-ft. level of No. 73 shaft cut Keewatin and several faults. Further work in this area cut three 4 to 5-in. veins assaying from 500 to 2500 oz. per ton. At shaft 81 Keewatin is expected at 535 feet.

KOREA

The Seoul Mining Co., operating the Suan concession in Whanghai province, Chosen, reports the following for March:

Bullion produced	$ 65,090
Concentrates	75,455
Total recovery	$140,545
Expenses	$ 55,000
Operating profit	$ 85,545

Copper is figured at 12c. per pound.

PHILIPPINE ISLANDS

The annual meeting of the Benguet Consolidated Mining Co. was held at Manila during February. The new mill near Baguio commenced work in September last, yielding a net profit of ₱42,010 in the past four months. The first half of February produced gold worth ₱27,294. The average output will be over ₱40,000 per month. The present 60-ton plant is to bo enlarged.

PERSONAL

Note: The Editor invites members of the profession to send him particulars of their work and appointments. This information is of unquestioned interest to our readers.

Jas. W. Neill is in town.

P. B. McDonald is at Ely, Nevada.

R. A. Kinzie has gone to Globe, Arizona.

Edgar A. Collins is at La Crescenta, California.

C. B. Kingston has left London on his return to Rhodesia.

W. De L. Benedict is expected in San Francisco, from New York.

T. J. Jones has left London on his return to Kyshtim, Siberia.

L. D. Ricketts, on his return from South America, has gone to Arizona.

Forbes Rickard was at Lovelock, Nevada, last week, going thence to Chicago.

E. A. Wallers has been elected president of the Transvaal Chamber of Mines.

Victor C. Alderson is manager for the Winnemucca Mining & Milling Company, Nevada.

Newton B. Knox has been appointed consulting engineer to the Minas de Phoenicia in Spain.

J. A. Burgess has been appointed manager of the United Eastern mine at Oatman, Arizona.

A. B. Hall has been appointed consulting engineer to the Aurora Mines Co. at Aurora, Nevada.

Henry M. Payne has been lecturing at several mining schools; this week at Rolla, Missouri.

S. W. Cohen, general manager for the Crown-Reserve Mining Co. at Cobalt, is touring in California.

C. Erb Wuensch has obtained an appointment on the staff of the Butters Salvador company in Salvador.

Edward E. Carpenter has been promoted from mill superintendent to manager of the Nevada Wonder mine at Wonder, Nevada.

F. W. Sperr addressed the Gogebic Range Mining Association at Ironwood, Michigan, April 22, on 'The Block Caving Method of Stoping Large Orebodies.'

William Thomlinson, representing British Columbia, has joined W. D. Dalglish and F. H. Mason on the mineral department of the Canadian Commission at San Diego.

H. P. Wherry, superintendent of the Fields Mining & Milling Co.'s mines, has resigned to become the head of a new organization to operate the Brown-Level mine, in Wisconsin.

R. B. Lamb has moved his office to 25 Broad St., New York. He is now consulting engineer to the Oatman Southern Mining & Milling Co. and the Pittsburg Mining & Milling Co., both operating mines at Oatman, Arizona.

Hunter B. Supplee, a well-known mining man in central Idaho, died at Philadelphia on April 6 of heart failure.

A. L. Horner, general manager of the Springfield Tunnel & Development Co. of Columbia, Tuolumne county, California, died last week after an illness of five months.

The Montana Society of Engineers is arranging a big meeting at Helena on June 6, 7, and 8. Trips are to be made to the lead smelter at East Helena, the power-plant of the Montana Power Co. at Hauer lake, and the Scratch Gravel mining district.

On May 2 the Chamber of Mines and Oil of Los Angeles holds its annual meeting and dinner. Address will be given by Seeley W. Mudd, Warren C. Kennedy, and Theodore Martin, while Edward L. Doheny has charge of a long film showing the Cerro Azul No. 4 oil-well, brought-in on February 10, 1916. Over 1,000,000 bbl. gushed-out before the well was under control.

THE METAL MARKET

METAL PRICES

San Francisco, April 25

Antimony, [illegible] per pound	12
Electrolytic copper, cents per pound	31
Pig lead, cents per pound	$8.00—$8.80
Platinum, soft metal, per ounce	$85
Platinum, hard metal, 10% iridium, per ounce	$89
Quicksilver, per flask of 75 lb	$125
Spelter, cents per pound	22
Tin, cents per pound	50
Zinc-dust, cents per pound	30

ORE PRICES

San Francisco, April 25.

Antimony 50% product, per unit, of 1%, or 20 lb	$2.25
Chrome 40% and over, f.o.b. cars California, per ton	12.50
Manganese 50% metal, 8% silica, per ton	12.00
Tungsten 60% WO_3 per unit of 20 lb	70.00

A drop in antimony ore is expected.

A further recession in the price of tungsten is looked for by the Foote Mineral Co. of Philadelphia in June and July, as a surplus will be thrown on the market. This firm is paying $58 per unit for 60% product, and a bonus of 25c. per unit for each unit over 60%, and a penalty for each under that percentage.

New York, April 19

Dealers report that the situation with regard to South American antimony is exceedingly difficult, inasmuch as there are buyers of the ore in New York, but the shipping difficulties are almost insurmountable. The freight-rate has been doubled, and still it is difficult to find cargo-space. The result is that sellers only offer on the basis of f.o.b. South American ports. The nominal quotation is $2.60 per unit.

The demand for tungsten is good and the market is firm. Small quantities have changed hands at $85 per unit, but larger buyers are unwilling to pay over $80. Tungsten also is adversely affected by the costly and inadequate freight service from South America, from where a large shipment arrived last week.

EASTERN METAL MARKET

(By wire from New York.)

April 25.—Copper is strong and active; lead is dull and independents quote lower; spelter is quiet and weak.

COPPER

Prices of electrolytic in New York, in cents per pound.

Granby Consolidated produced 3,555,411 lb. in March, an increase of nearly 1,000,000 lb. over February.

Braden in 1915 yielded 36,397,398 lb. The net profit was $1,647,776, against a deficit of $13,523 in 1914.

SILVER

Steadiness, then strong upward movements are features of the market. There is strong demand for English and Continental coinage and to some extent for India. American supplies for export are moderate, sellers being reluctant, and as long as this is so, further strength is expected in London. Late in March 6,000,000 oz. was transferred from China to India suggesting buying by the Indian mint. An April 22 silver worth $126,362 was sent from San Francisco to China. A report on trade between China and Japan in 1915 shows a remarkable change in value due to the fall in silver last year.

Tin is quiet at 49.50 cents.

Eastern Metal Market

New York, April 19.

The big buying of copper has subsided, leaving prices firm and producers pretty well sold-up for the next four months. Sales of fairly prompt metal have been made at 30c. It is estimated that 300,000,000 lb. is under contract. The zinc trade paused to digest the figures of the U. S. Geological Survey on the 1915 production and notes for 1916, but it is not thought that the increased production indicated will depress the market in the near future. What will happen after the War is another story. Lead has been dull on all sides; the crux of this metal situation lies in foreign demand. If it is renewed on a large scale prices will advance again, whereas domestic consumption alone is insufficient to hold them up. Tin is easier because of larger arrivals. Antimony is easier for the same reason. Aluminum is a trifle lower.

Exports of war munitions of all kinds—iron, steel, and metal products, are at their height, and likely to continue at full flood for some time. It is to be noted, however, that E. R. Stettinius, of the firm of J. P. Morgan & Co., fiscal and purchasing agent for Great Britain, on his recent return from London, brought no war orders with him and, when interviewed, stated that England and France were working at full capacity in making shells and he doubted that further orders for shells would be placed here. There is, however, heavy enquiry for steel rounds wherewith to complete orders in hand. The metal-working machinery line is quieter, although there is a good volume of scattered buying on the part of domestic manufacturers. Pig-iron is strong, but not especially active. Steel rails have been advanced $5 per ton. Strike troubles are cropping up in many directions. To forestall trouble, apparently, the U. S. Steel Corporation has announced a general wage advance of 10%, effective May 1.

COPPER

For the present the large transactions are about over, not only because buyers are satisfied, but as producers have no metal to offer in quantities of important size this side of September. They are sold up for the next four months. It is estimated that during the big movement contracts were written for about 300,000,000 lb. Domestic consumers have continued in the market since the heavy purchasing subsided last week, and for prompt lots are paying premiums of 1½ to 2c. per lb. Electrolytic for September delivery is quoted at 28.50c., cash, New York. Lake for the same delivery is nominal at 28.75c., cash. May, June, and July electrolytic are quoted at 29 to 30c. A large quantity for June and July was taken on April 18 at 29.50c., and some May, June, and July at 30c. In fact 30c. copper is closer than it has been since the War started. Nearby positions are scarce. Lake is practically unobtainable this side of September, its nominal price for later deliveries being about 28.75c. Sales of high-grade Lake for nearby delivery are reported at 31c. The London market is strong at £138 for spot electrolytic. Cabled statistics show that stocks in Great Britain and France made a gain in the first half of April. On the 15th in the two countries stocks totaled 6807 tons, against 5528 tons on March 31, and 7988 tons on March 15. Exports in 18 days of April amounted to 14,273 tons. The domestic market continues remarkably firm despite the lessened activity.

ZINC

Last week there was some heavy buying, but it has tapered off, leaving quotations firm at higher levels. The New York quotation for prompt or April spelter yesterday (the 18th) was 19.25c., and that at St. Louis 19c. May delivery was quoted at 18.50c., St. Louis, and June at 17.75 to 18c. St. Louis. Third quarter can be done at about 16.50c. St. Louis. A moderate business is now being done. The trade is intensely interested in the report on 1915 production made by C. E. Siebenthal of the U. S. Geological Survey, particularly in the figures bearing on the number of retorts to go into operation this year. At the beginning of 1916 there was under construction or contemplated 26,992 new retorts, whereas the number now is 49,612, making a total in operation, building, or contemplated no less than 206,270, capable of producing about 825,000 tons per annum. To this quantity must be added about 60,000 tons which, it is expected, will be produced in electrolytic plants. There are rumors of other zinc smelters. These figures, in the eyes of the trade, constitute a bear argument when the distant future is considered, but it is not thought that they will have any considerable effect on nearby prices. For one thing, the producers are well sold-up for this quarter, and a big demand is expected to develop for the third and fourth quarters. As for the future it is not expected that the market will hold to its present levels, although supporting influences will be consumption by the galvanizers whose buying has for months been far under normal. Until the War ends it cannot be forgotten that the United States is supplying the bulk of the spelter used in the world. The German and Belgian supply is confined to those countries. Great Britain is encouraging smelting in the United Kingdom, but a plentiful supply of ore, which must come from Australia and Mexico, cannot be had. The upset shipping conditions, and the troubles in Mexico are practically prohibitive. Exports in 18 days of this month totaled 1279 tons. The London quotation for spot on the 18th was £103. Sheet zinc is unchanged at 25c., f.o.b. mill, 8% off for cash.

LEAD

The market has continued dull, and the prices of independent producers show an easier tendency. The situation in lead may be summed up briefly as follows: All depends on export demand; if it is heavy it would not be surprising to see prices advance, if it does not materialize, prices certainly will recede. The domestic demand alone will not maintain present levels, let alone send them higher. In the past few days the export demand seems to have disappeared, and domestic consumers have shown themselves to be unwilling to pay the prices asked by independent producers, all of which has brought about a dull market. The A. S. & R. Co. continues to quote 7.50c., New York, and 7.42½c., St. Louis, but these quotations merely serve as a basis for averages. Independents ask 7.75c., New York, a price which probably could be shaded, and 7.62½c., St. Louis. The leading interest has booked some business, but not much has been done elsewhere. Exports in 18 days of this month were light, amounting to only 747 tons. The London quotation for spot on the 18th was £35 2s. 6d.

TIN

The quotation for spot tin yesterday (the 18th) was down to 51c., in a quiet market. In fact the market has been dull almost continuously, the only business of importance being last Friday (the 14th) when 300 tons changed hands. Consumers are well supplied for their current needs, and fairly large arrivals in the past few days have cleared-up apprehension on that score. Up to April 18, 1345 tons had arrived this month, and 5464 tons was afloat. A good part of the tin afloat is coming direct from the Straits Settlements, and will not be held-up at London or Liverpool.

ANTIMONY

Some fair-sized arrivals from Japan are offered and these, with the absence of buyers, have created an easier market. Spot Chinese and Japanese is offered at 41 to 42c. New American producers continue to be reported.

COMPANY REPORTS

EL PASO CONSOLIDATED GOLD MINING CO.

During 1913 and 1914 this Cripple Creek company made no profit, but last year that from 24,418 tons of company ore and royalty from 9991 tons of lessees' ore was $37,133. Debts were reduced from $70,000 to $17,500. On April 1, 1916, the treasury contained $1973. Sixteen leases are in force to the 700-ft. level. The company did 4230 ft. of development, and has 7000 tons of ore broken and 12,000 tons ready for breaking. Low-grade ore in the mine and on dumps may be treated by flotation, either on a royalty basis or by the company. Joseph J. Darnell is superintendent.

TONOPAH MIDWAY MINING CO.

During 1915 lessees worked from No. 1 shaft, there being 40 men at work at present. The company sank No. 2 to 1330 ft. depth. At 1265 ft. a vein 15 ft. wide of $3 to $15 ore was cut. When opened from the 1300-ft. level this vein was flat in faulted country. At 137 ft. north from the shaft at 1330 ft. a vein 70 ft. wide was passed through, worth from $2 to $6 per ton. A winze opened $10 to $12 ore, but water was found, and work temporarily suspended. A total of 1057 ft. of work was done at $7.60 per foot. Shaft-sinking cost $42.79 and winzing $26.94 per foot. Total expenditure was $25,789. Revenue, including $33,401 from assessments, and $11,089 from royalties, totaled $54,126. A balance of $12,070 remains for 1916. W. J. Douglass is superintendent.

YUKON GOLD CO.

This company operates in Alaska, California, and Yukon territory. Results may be tabulated as follows:

	Cubic yards	Gold recovered
Alaska (Iditarod)	926,956	$845,998
California (American, Butte, and Feather rivers)	3,818,126	437,852
Yukon (dredges at Dawson)	5,041,075	2,456,597
Yukon (hydraulicking at Dawson)	3,031,647	412,535
Total	12,817,804	$4,152,982

Expenditure in each district was $358,407, $172,118, $1,333,908, and $243,247, respectively. The profit was $2,121,031, about $200,000 less than in 1914. Dividends totaled $1,050,000. Additional ground was purchased in Alaska and California, in the Ruby and Trinity regions.

Recoveries and costs were as follows:

	Gold saved Cents per yd.	Cost Cents per yd.
Dredging in Alaska	91.30	38.70
Dredging in Yukon	48.73	26.46
Dredging in California	11.46	4.51
Hydraulicking	13.60	7.00

INSPIRATION CONSOLIDATED COPPER CO.

During one day early in April this company's mine at Miami, Arizona, produced 18,000 tons of ore without any effort; a year ago the experimental mill was receiving 600 tons a day. This comparison should indicate the progress made during 1915. The report of the general manager, C. E. Mills, includes the following for the past year:

No attempt was made to develop additional ore, so reserves remain as before, namely, 97,143,000 tons averaging 1.63% copper. Underground work preparatory to mining totaled 109,546 ft., and 337,130 ft. to date. With the caving system of ore extraction it will be possible to make a large output with relatively small labor force and at a low cost.

The first unit of the new mill started work on June 29, 1915, the last in February 1916. Twelve were operating at the end of December. There was treated 778,851 tons of 1.702% ore, yielding 20,067,310 lb. copper, with 79.95% recovery. Oxide ore sent to the smelter added 378,360 lb. to the mill total. The cost was 8.136c per pound of copper for all departments. Of the 20,445,640 lb. produced, 6,134,355 lb. was delivered, realizing $1,138,878. Including the metal on hand the profit was $600,062. An initial quarterly dividend of $1.25 per share was paid on May 1, 1916.

PLYMOUTH CONSOLIDATED GOLD MINES

Companies operating on the Mother Lode of California would profit by reading the report of this company for 1915, as it shows how a report should be published for shareholders and the public. Although signed by the general managers, Bewick, Moreing & Co., the superintendent at the mine is James F. Parks.

Development covered a total of 4517 ft. The main shaft was sunk 296 ft. on the incline to a vertical depth of 2360 ft. Ore-bins were cut-out at 950, 1065, 1200, and 2300 ft. A new level has since been opened at 2450 ft. At 1200 ft. depth an east cross-cut was driven 77 ft., and from 40 ft. to that point 73 in. of ore averaged $9.60 per ton. On the 1400-ft. level a north drift off the raise advanced 191 ft. in $9.60 ore for a width of 113 in. A raise south, extended 158 ft. in ore, averaged $11.04 over 85 in. A south drift opened 70 in. of $6.72 ore over a length of 86 ft. At 1500 ft. is 123 in. of $4.32 ore; at 2000 ft. 60 in. of $4.08 ore between 37 and 202 ft. north. At 2150 ft. the main north and south drifts opened 65 and 90 ft. of $10.56 and $12.48 ore over a width of 62 and 138 in. respectively. At 2300 ft. there is 90 ft. of $5.04 ore across 67 in. in the north drift. The south opening is in ore of irregular value. There was mined from 8 levels a total of 129,500 tons.

The mill recovered 22,098 oz. gold and 5925 oz. silver by amalgamation, while concentration saved 9095 oz. and 2727 oz. respectively. The average yield was $4.95 per ton.

The cost was as follows: Development, 46c.; mining, $1.59c.; milling, 38c.; bullion and concentrate, 25c.; maintenance and general, 32c.; a total of $3 per ton. The net profit was $188,000, of which $173,000 was paid in dividends. The balance for 1916 is $12,000, against $1060 brought forward to 1915.

FEDERAL MINING CO.

This is a subsidiary of the American Smelting & Refining Co., and operates mines and mills in the Coeur d'Alene, Idaho.

A comparative report for the past two years is as follows:

	1915	1914
Operating earnings	$2,782,658	$2,200,777
Total deductions	2,326,719	2,011,684
Operating profits	$ 455,939	$ 189,093
Other income	352,662	702,463
Total income	$ 808,601	$ 891,556
Charges	498,234	339,160
Balance	$ 310,367	$ 552,396
Preferred dividend	479,443	599,304
Deficit	$ 169,076	$ 46,908
Previous surplus	1,388,614	1,435,522
Total surplus	$1,219,538	$1,388,614

Cash on hand December 31 amounted to $548,703.

There was mined at all properties 461,252 wet tons of ore, of which 29,371 tons was first class. There was milled 408,315 dry tons, an average of 34,026 per month. Reserve milling ore on January 1, 1916, amounted to 1,107,600 tons; 131,370 tons of concentrate, and 68,108 tons of first-class ore. There was

produced 66,610 tons of lead concentrate, and shipping ore averaging 40.20% lead and 14.77 oz. silver per ton; 8839 tons of zinc shipping ore and concentrate containing 42.46% zinc; of this amount 29,338 tons was first-class shipping lead ore which carried from 22.95 to 52.25% lead and averaged 30.43%.

GOLDFIELD CONSOLIDATED MINES CO.
AURORA CONSOLIDATED MINES CO.

As the first named controls the other, the report of these two Nevada companies may be considered together. J. W. Hutchinson is general manager for both, and the following notes are from his report for 1915. At Goldfield the mine and mill superintendents are J. B. Kendall and J. B. Lain, respectively, while at Aurora, R. A. Hardy is the general superintendent.

Development amounted to 34,603 ft. at a cost of $5.73 per foot. No discoveries of unknown orebodies were made during the year, but exploration was directed toward ground in which there are chances of finding extensions of known shoots. Reserves of measurable ore amount to 105,000 tons, but it is safe to say that 250,000 tons can be counted in addition. Some ore was extracted by lessees. There was one fatal accident in the mine due to carelessness of the miner. The copper-gold ore is to be treated by flotation. This ore occurs below the 750-ft. level, and little development has been done there of late pending final results of testing. There was extracted 335,553 tons of milling ore by the company, and 11,162 tons by lessees; also 4154 tons of copper-gold ore for the smelters. The Mohawk mine contributed 193,802 tons of ore. Stoping cost $2.67 per ton. Square-set stopes produced 81.19% of the total.

The mill treated an average of 1057 tons per day, a total of 385,900 tons, averaging $10.37 per ton. Of this, 43,339 tons of $5.99 ore was from dumps. The recovery was 90.45%, at a cost of $1.414 per ton, a reduction of 22 cents. The net cost in all departments was $5.02 per ton, a decrease of $1.03. The total bullion saved was $3,621,269. Smelter settlements, etc., brought the net revenue to $3,515,834. The operating profit was $1,558,308. One dividend of 15c. and three of 10c. each were paid, a total of $1,601,617. Cash at the beginning of the year was $655,703; at the end $573,370.

Total production to date is 2,506,139 tons of ore for $67,323,101, an average of $27.06 per ton, and $28,999,832 in dividends, or $8.15 per share.

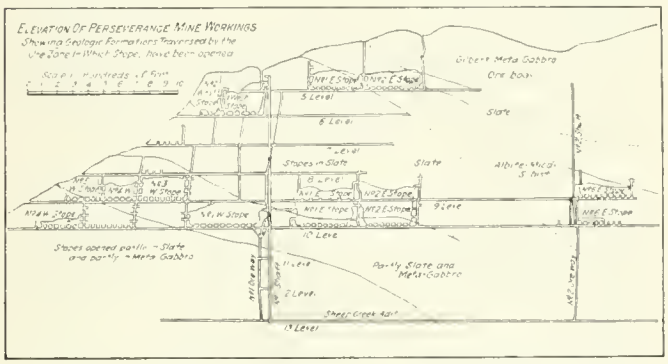
Owing to treatment troubles the Aurora Consolidated mill was idle in February and March of 1915, when new filters were installed. There was treated 138,399 tons of ore, averaging $4 per ton. The operating profit was $32,984, but new construction turned this into a loss of $22,377. Costs totaled $3.216 per ton, excluding new plant. The company's debt is $400,000.

Development amounted to 4900 ft., at a cost of $8.10 per foot. Ore reserves are estimated at 414,000 tons, 365,000 of which are in the Humboldt vein. Neither the quantity of ore nor the grade thereof has checked the original estimate, so it is probable that the investment of the Goldfield Consolidated company in the Aurora may not be profitable. However, there is much unexplored ground with possibilities.

ALASKA GOLD MINES CO.
ALASKA GASTINEAU MINING CO.

Accompanied by plans and photographs the report of this company for 1915 is of special interest, in view of the scope of operations and criticism that has been leveled at the undertaking generally. The managing director, D. C. Jackling, reported that the year was one of particular interest. In July 1912 it was estimated that the general program would admit of part of the plant being operated by the first of 1915; this actually commenced on February 12. By November the mill was treating 6000 tons per day. To supply power for 12,000 tons daily, the Annex scheme of 4000 hp. was partly finished. Operations have shown that the mill is capable of dealing with 10,000 tons in March 1916. At the mine another 3000-cu. ft. compressor was installed, a concrete dry-room erected, machine-shop re-arranged, the Sheep Creek railway improved, snow-sheds built, the whole being able to handle 12,000 tons per day.

Development totaled 17,346 ft. of openings, and 5943 ft. of diamond-drilling. Actual operation and stoping divulged new and important facts relative to the distribution of gold. The highest grade ore occurs in the schist body opened in No. 2 east stope on No. 5 level, and No. 6 east on No. 9 and 10 levels, this schist having a strong 'rake' to the east, appearing farther away from the central shaft and workings on deeper levels, until at No. 10 it is first encountered east of No. 2 shaft. The ore from this section averaged $2 per ton by sampling and mill runs. The slate orebody is the lowest grade so far de-



veloped, particularly west of No. 1 shaft, where the vein widens to 140 and 210 ft. East of the shaft below No. 5 level the slate orebody is narrower and higher grade. West of the shaft below No. 9 and down to the Sheep Creek level the deposit is of meta-gabbro and slate. Sampling has shown better ore than in the slate body. It had been decided from sampling, etc., that if a mixture of ore of 25% of schist, 25% of one slate, and 50% of another slate, the mill could be supplied with ore of average grade. This was proved true, but as mining progressed, it was found, due to the rake of the schist orebody, that No. 6 stope east on No. 9 level rapidly passed out of the schist into lower grade slate; and No. 1 stope east on No. 5 level, lying under the schist, did not supply as high grade ore as was expected, because the underlying slate caved away and prevented any mining in the schist at all, thus giving poor ore, whereas high-grade ore had been counted on. Later on this schist orebody will contribute such ore when attacked from another direction. This resulted in less ore being sent to the mill and the grade dropping to nearly $1 per ton, details of which have already been published. Ore broken in stopes at the end of 1915 totaled 1,400,984 tons, an increase of nearly a million tons compared with the quantity at the beginning. The cost of ore-breaking was 17.22c. per ton, plus 5.25c. for preparing new stopes. Underground tramming cost 4.997c.; and on surface, 3½ miles to the mill, 3.641c. During November, the month of maximum tonnage, ore was delivered to the plant for 28.499c. per ton.

The mill treated 1,115,294 tons of $1.1569 ore, with 81.06% recovery. Tailing assayed 21.91c. The average cost of milling was 30.496c., but on 6000 tons a day it was down to 25.699c. Every cost made a total of 69.039c. per ton. The year's results in all departments were uniformly satisfactory, and more than confirmatory of estimates, except the grade of ore delivered.

Of the gold recovered worth $1,046,104, the profit was $251,848, plus $26,923 miscellaneous.

Operating officials at the mine are B. L. Thane, manager; G. T. Jackson, assistant manager; B. B. Nieding, superintendent of mines; H. L. Wollenburg, chief engineer; and E. V. Daveler, superintendent of metallurgical department.

BOOK REVIEWS

Six Place Logarithms. By Horace Wilmer Marsh. P. 155. John Wiley & Sons, Inc., New York. For sale by the Mining and Scientific Press. Price, $1.25.

This is a well printed book of six-place logarithms arranged in the usual way. The table of logarithms of numbers has the first three figures of the number in the margin. Columns across the page give the fourth figure. The tables of logarithmic sines and tangents are figured for ten-second intervals. Proportional parts for interpolation are given in the tables for both the numbers and the trigonometric functions. There is also a seven-place table of lengths of circular arcs and a few miscellaneous mathematical tables. There is a short chapter of instruction for the use of the tables, which is entirely correct as far as the tables themselves are concerned, but which might give the novice the impression that logarithms must necessarily be to the base 10. The book will be of value both in the class-room, drafting-room, and office, rather than in the field. Since four-place tables are usually sufficient in the field, this is not a matter of importance.

The Mining World Index of Current Literature. Vol. VIII, last half year of 1915. By Geo. E. Sisley, Associate Editor of *Mining & Engineering World*. P. 288. Index. Published by the Mining World Co., Monadnock Bdg., Chicago. Can be obtained through the Mining and Scientific Press. Price $2.

An index of engineering articles sounds attractive to a neophyte. He imagines that by consulting such an index it is possible to immediately find exactly what he wants. It must be admitted that occasionally this works out nicely, but most indexes are an introduction to a Chinese puzzle. As to the Mining World index it can be said that a good deal of credit is due to the compilers not only for the assiduous scanning of a tremendous array of publications in half a dozen languages, but for the policy of giving more importance to the author than to the title of the article indexed. Titles are delusions, authors are remembered. For the rest, the Mining World index is sufficiently well known to need no introduction. The chief criticism has been that an index published by a paper of the same class is likely to give unmerited attention to the articles appearing in its own columns.

U. S. Bureau of Mines, Washington, D. C., 1916:

How a Miner Can Avoid Some Dangerous Diseases. By A. J. Lanza and Joseph H. White. Miners' circular 20. P. 26. Illustrated. Practical notes on an important subject.

Economic Methods of Utilizing Western Lignites. By E. J. Babcock. Bulletin 89. P. 73. Ill., index. The largest workable deposits of this kind of coal are in North Dakota, Montana, Wyoming, Colorado, and Texas, the first named being the greatest. Their importance has not been appreciated nor have they been adequately utilized.

Graphic Studies of Ultimate Analyses of Coals. By Oliver C. Ralston, with a preface by Horace C. Porter. Technical paper 93. P. 14. Ill., charts.

Abstracts of Current Decisions on Mines and Mining, May to September, 1915. By J. W. Thompson. Bulletin 113, law serial 6. P. 122.

Manufacture of Gasoline and Benzene-Toluene from Petroleum and Other Hydrocarbons. By W. F. Rittman, C. B. Dutton, and E. W. Dean, with a bibliography (41 pages) by M. S. Howard. Bulletin 114, petroleum technology 29. P. 268. Ill., index. This important publication should be secured by all interested in oil and gasoline, especially at this time when so much is being said about gasoline.

INDUSTRIAL NOTES

In the April 'Leschen's Hercules,' among other interesting matter is a brief description of the plant that manufactures Leschen wire rope at St. Louis, Missouri.

'Roebling Wire Rope' is the name of the bulletin of John A. Roebling's Sons Co., Trenton, New Jersey, giving information of service to wire-rope users. Special articles are written by engineers of the company, citing examples of good wire-rope practice. Particular attention is given to the care and proper use of wire rope in service.

On and after April 17 the Los Angeles office of the Pacific Tank & Pipe Co. will be at rooms 910-912 Trust and Savings building, north-west corner of Sixth and Spring streets. The company has just erected a new and larger plant at East Wilmington, which is near the harbor of Los Angeles, and is equipped to complete business in better ways than before.

Bulletin No. 56 and others (48 pages) of the Byron Jackson Iron Works, Inc., of San Francisco, are all about the pumps that this firm manufactures, including the following: Belt-driven centrifugals for irrigation, direct-connected centrifugals, single-stage centrifugals, dredging gravel and slime pumps, improved deep-well turbine-pumps, and multiple turbine and series centrifugals. All kinds of mine pumps are described and illustrated. Useful data are also given.

'Waterproof Graphite Grease' is the title of a new 16-page booklet published by the Joseph Dixon Crucible Co., Jersey city, New Jersey. This useful little book explains concisely and clearly how many difficult lubricating problems have been overcome. It also deals with the care and up-keep of heavy, slow-moving machinery and parts that are exposed to unusual wear. Some of the subjects treated are lubrication of elevator plungers, the best way to handle wire rope, open gearing, dredge machinery, and rolling-mill lubrication, the lubrication of sugar-rolls, pulp, and paper machinery.

It is usually the case that a man interested in one line of goods does not care for anything except that particular line, and it means a saving to the firm which he purposes to patronize to send out the catalogs to a much larger list of consumers and give each one more complete data on the particular lines in which he is interested.

Such a catalog has just been published by the Smith-Booth-Usher Co. of Los Angeles. Instead of issuing one complete catalog containing all of its lines, there has been issued a catalog on the unit basis, namely, a separate catalog for each line of goods. For instance, one catalog covers pumps, engines, motors, and irrigation supplies; another contains garage machinery; while others contain pipe and fittings, valves, wood-working equipment, contractors' supplies, elevating, conveying, and power-transmission machinery, belting and pulleys, mining equipment, street contractors' supplies, etc. By furnishing separate catalogs in this way the firm is enabled to give much more complete data on each particular line than would be possible if all was combined in one book.

The Meese & Gotterfied Co. has adopted the sectional form in issuing its new general catalog, and section No. 1 of 9th edition Catalog has just been received. This first section is one of the best publications of its kind. It treats of a portion only of the firm's line of conveying, elevating, screening, and mechanical power-transmitting machinery; that is, pulleys, couplings, shafting, etc., but is full of important data making it of permanent value to the engineer or plant superintendent. Of special interest is the descriptive matter it contains on 'short-centre' belt-drives, a departure from the usual methods of belt-driving, which makes it possible to install belt-drives under conditions where heretofore high-speed chains alone were considered practicable.

EDITORIAL

T. A. RICKARD, Editor

SILVER at 74⅞ cents is the highest since 1892; it compares with the low price of 46¼ on September 1, 1915. Gentlemen of Tonopah and Cobalt, shake!

UNDER 'special correspondence' we give our readers an interesting letter from Johannesburg. It is written by an engineer 'in the know' and contains some frank—and therefore useful—comment on Rand affairs.

TO Mr. Courtenay De Kalb we are indebted, in this issue, for a scholarly article on the origin of nitrate. The conditions under which this chemical deposit is produced in nature have been the subject of previous discussions in our pages; this time Mr. De Kalb finds an interesting analogy—incomplete as it may be—between New Mexico and Chile. If the Rodeo valley were five times more arid it might have compared with the Andean plateau as a place for the natural accretion of nitrate.

AMONG the resolutions passed by the Republicans of Boulder county, Colorado, was one demanding a tariff of $50 per unit on tungsten, in order to kill competition from Australia and Portugal. This was unnecessary. The Australian government has placed an embargo on the shipment of tungsten anywhere exeept to England and her allies, and has fixed a price of $11.50 per unit of 65% product at seaboard. As to Portugal, we think it unlikely that any tungsten ore will come from that country to the United States, all the output being commandeered for use in England and France, at least for the duration of the War.

STRAIGHT TALK on metallurgical practice is of the greatest value to smelter-men: it is rarely possible to obtain information that has not been censored by authority or bowdlerized by convention. The roasting of lead ores just now is a subject of timely interest by reason of the starting of new lead-smelting plants in the North-west. It is difficult to obtain an unvarnished record of experience in this branch of technology, therefore the description, analysis, and criticism of the practice at East Helena should prove useful. The author's name is not given, but it will be obvious from the reading of the article that he is 'on the spot' in more senses than one.

THAT old yarn about Carrie Everson and the discovery of flotation is being revamped, with a Californian setting. That erudite newspaper *The Evening Howl* publishes a eock-and-bull story about a Miss Harriet Everson who discovered the process while on a visit to her brother at Kennett, in Shasta county. The cleaning of some pans, the spilling of kerosene on a copper-gold ore, and laughter at the absurd floating of the valuable minerals furnish the chromatic details for another myth. The lady is said to have obtained a patent, but she was obstructed by the numerous other patents taken out by "some Italians in California." Shades of Froment! Finally, her case is said to illustrate "how a fortune was missed by a hairbreadth." No; it illustrates how wilfully ignorant the daily press is, and nothing more.

ONE good feature of the rise in metals is that it is enriching a number of small operators; for instance, in southern Missouri the rise in zinc has doubled the number of persons paying income-tax this year as compared with the year before; and in the same way the exploiting of tungsten deposits on lease, in Colorado, Arizona, and Idaho, for example, has given a lot of men without capital the chance to win a fortune. Similarly the demand for quicksilver, magnesite, and manganese in California and Nevada has enabled many small operators to make a handsome turn by aid of the simplest equipment. Honest digging of mineral from the ground is prospering so greatly just now that the stock-market game has lost much of its attractiveness. The uncertainty as to metal prices gives sufficient speculative zest.

CONSIDERING the lavish publicity given by the *Boston News Bureau* to the Kenneeott agglomeration, we are surprised pleasantly to see that interesting and enterprising paper giving a warning in regard to the huge capitalizations of copper companies and suggesting that speculators should not neglect to make enquiry into the number of shares issued against a given property. The Chile Copper and the Kennecott have 4,400,000 and 2,754,625 shares, respectively. This affords a violent contrast, for example, with the 100,000 shares of the Calumet & Hecla company, which has paid $131,000,000 in dividends. Indeed, at one time the State of Michigan forbade an issue exceeding 100,000 shares against any copper mine, indicating how archaic old ideas have become in this branch of industry.

OUTCROPS and their story will always interest the miner, for by them he is guided in his search for the hidden ore. We take pleasure in publishing the first of a series of artieles on 'Surficial Indications of Copper,' prepared by Mr. Frank H. Probert, Professor-designate of Mining in the University of California. The author

has had an experience fitting him to treat the subject from the economic point of view, that is, from that of the mining engineer. The first photographic illustration is an example of the kind of evidence most desired by the prospector, namely, the presence of rich ore. The mass of nearly pure copper sulphide in the limestone forming the crest of a snow clad range in south eastern Alaska has proved to be the top of a great bonanza, now being exploited by the Kennecott Copper Company. The more subtle signs of mineralization that led to the uncovering of the immense masses of enriched porphyry and schist, constituting the disseminated chalcocite deposits of Utah, Nevada, and Arizona, will be described in the later articles of this series. The subject is much to the point: for, after all, the first act of mining is to find ore. We must confess that the finding is usually less scientific, more accidental, than the mining and metallurgical operations that follow the discovery. Hitherto the mining engineer has had to follow in the tracks of the unsophisticated prospector, exploiting what his nomadic friend first explored. Only in recent years has the science of ore deposits achieved its economic purpose in furnishing an intelligent explanation of the processes whereby ore concentrations, particularly of copper, are formed underground. Even now, the amount of confident knowledge on the subject is small; all the more reason for making the most of it and of testing it as we proceed.

WHERE the zinc has gone is shown in recent statistics published by the Geological Survey. From these it is seen how the export of domestic spelter was 987 tons in the first 7 months of 1914, as compared with an exportation of 63,820 tons in the last 5 months of that year, and 70,349 tons in the first 7 months of 1915. Then the rate slackened so that in the last 5 months of last year the total exported was 47,447 tons, making the total for the year, 117,796 tons, as compared with 64,807 in the whole of 1914. Production rose from 353,049 to 489,519 tons, or at the rate of 39%, while domestic consumption increased from 299,125 to 364,382 tons, equivalent to 22%. The difference between these two increases was more than compensated by the exportation, which increased 82%, as shown above. Meanwhile the smelter capacity has been increased from 115,114 retorts at the end of 1914 to 156,658 at the close of 1915, and it is estimated that a further addition of fully 50,000 retorts is assured during the current year, bringing the total capacity to over 200,000 retorts, equivalent to an output of 825,000 tons. Taking into account the output of secondary and re-melted spelter, the United States will be in a position, at the end of 1916, to produce 900,000 tons, or nearly three times the probable domestic demand. In 1913 the world output of zinc was 1,102,456 tons. Obviously, the ending of the War will puncture this inflation of American productivity. The Geological Survey bulletin suggests that the smelting of the Australian output in this country would obviate a collapse, but we know already that most of the Broken Hill companies have arranged for the treatment of their product in Australia on the basis of long-time contracts; and that of the two companies not included, one has a smelter in England and the other will make similar arrangements as soon as it can. Therefore no help is to be expected from Australia. In short, the present price for spelter is linked with the duration of the War.

MEXICAN affairs continue in a state of flux. The conference at El Paso between General Alvaro Obregon and General Hugh L. Scott, representing the military establishments of the two countries, has not been definitely concluded at the time of this writing, but it is clear that President Wilson will not consent to a withdrawal of the American expedition under General Pershing. If that expedition can remain where it is without provoking war with the Carranza government, it will be a consummation as unexpected as it will be satisfactory; for, once established in Northern Mexico, the American troops will be able to restore order and set an example that may lead to the final pacification of the country. The position is ticklish and forecasts are dangerous, but there is a good chance of our being able to avoid war. If on the other hand, Obregon insists on the withdrawal of General Pershing and his command, there will be nothing for it but to stand pat. We refuse to imagine that Mr. Wilson will indulge in another veracrusade; a retreat would invite attack and create the idea among the Mexicans that the American troops had been repulsed, whether by Villa or Carranza will be immaterial—it will be quite enough to encourage sniping and cutting of lines of communication, to be followed, of course, by counter-attack on the part of our men, and so to organized warfare. In short, the conference at El Paso will decide whether the United States is to remain a friend or become an active enemy of the Mexican government.

RESUMPTION of work at the Bishop Creek mine, in Inyo county, is mentioned as a possibility, if Mr. Gaylord Wilshire, the promoter of the enterprise, can collect adequate funds for the purpose, which includes the enlargement of the mill, now one of 10 stamps only. This mine has been the subject of some curious finance, in which Mr. Wilshire, Socialists, and British Guiana have featured at various dates. It appears that the promoter has been backed by several thousand Socialists; we know of no reason why they should not make good stockholders, but we can see that theoretically it is all wrong for a Socialist to draw the unearned increment of a productive gold mine. However, that is a detail. We see better reason why stockholders in a Californian mine should not be dependent for dividends on a property in British Guiana, by exchange of shares and interlocking of interests. That also may be said to be an academic objection, because no dividends did accrue. Then followed 'Safety First' $55 notes, and 'Convertible 10% bonds.' All this was spread over six years. Now, Mr. Wilshire proposes to consolidate the wreckage

of all these past promotions, forming a Consolidated Wilshire Mining Company to be launched on an assessment of 6 cents per share wherewith to double the size and capacity of the mill at Bishop Creek. Whether the mine will earn more money with 20 stamps than with 10, we do not know. Doubling a mill does not always turn a losing operation into a profitable: sometimes it increases the loss as well as the tonnage. Mr. Wilshire, we believe, has not had sufficient experience in gold mining to pass judgment on a technical question of such immediate importance to 6000 shareholders. We suggest, in his own interest no less than in that of his supporters, that good professional advice be taken before the financial position is further complicated.

Quicksilver

Quicksilver has dropped to a nominal price of $100. Last week an auction sale of 192 flasks in this city ended in a fiasco, the two lots being 'bought in' by the seller at $100 and $105. In the middle of February the price was $300 per flask. The sudden break was due to unexpected shipments from Europe. The British government, on behalf of the Allies, had placed an embargo on export, so that quicksilver on the London market has remained steadily at £16½, or $80, per flask, but when the scarcity in this country caused the price to soar, a protest was made by the Du Pont works, the chief manufacturer of fulminate for the Allies. Whereupon the British government gave permission to the Rothschilds, controlling the European production of mercury, to make some shipments to the United States, most of it going to the Du Pont works, but some of it to the California Cap Company, which manufactures fulminate for industrial uses only, that is, for blasting caps. When therefore a shipment of 1900 flasks arrived at New York from Spain, followed by 1100 more from Italy, and altogether fully 5000 flasks were sent across the water in about two months, the market broke with a suddenness that astounded many who had begun to speculate in the metal, more particularly in San Francisco. Moreover, the boosting of the quotation to six or seven times the ante-bellum price did have the effect of attracting the metal from a variety of places, for example, the stock held in reserve by sundry gold-mining companies and the 'quick' stored at silver mines in Mexico that had substituted cyanidation for pan amalgamation. Again, at $300 it paid to apply rough water-concentration to many old dumps and extract small amounts, which, cumulatively, had an immediate effect on the market. After all, the normal annual production in the United States is only 20,000 flasks, so that a small increase lowers the price, unless the War demand is more than enough to absorb the new supplies. Concerning that, it would appear that production can be stimulated greatly by high prices and the War demand would have to last for several years before the easily accessible sources of supply were exhausted. In short, quicksilver is not likely to rise above its present quotation.

A World View

In one of those periodical pamphlets of useful information issued by the National City Bank of New York we found the statement that "obviously, Americans in business life who will lead in the future will be men of broader outlook than in the past—men with the 'world view'." That means, presumably, that the American of the future will try to understand foreign peoples preparatory to engaging in trade with them; that he will study historical geography in order to obtain guidance in his commercial expansion; that he will learn languages instead of fencing himself in a Monroe doctrine of linguistic incapacity. There is a distinct movement in this country toward a better comprehension of the ideas of foreign customers and a more intelligent appreciation of the ways of alien markets. Classes in Spanish, for example, are symptomatic of the belief that opportunities for enterprise are likely to offer themselves in South America. The notion is spreading that the industries of the United States are outgrowing domestic needs and that expansion abroad will prove profitable at an early date. For much of this the Great War is responsible; it has shattered the provincial egoism of our people, making it clear that no pronouncement of our own —whether by President Monroe or President Wilson— can ensure that avoidance of entangling alliances which was the avowed aim of the founders of this republic nor the splendid isolation that was the dream of doctrinaire statesmen, say, two years ago. The logic of events is incontrovertible. A condition, not a theory, confronts us. Facts are stubborn teachers. The American of the future will recognize them, lest he become a thing of the past. He will get "the world view," says the energetic New Yorker. What is that? We have mentioned some of the things it means, but a deeper significance is to be found in the phrase: it means leaving the parish pump and climbing the hillside; it means abandoning the valley road and ascending the snowy range; it means that a parochial self-sufficiency is to be discarded in favor of a wider mental horizon and a broader human outlook. Can we, as a people, reach that nobler altitude without the discipline of a great experience? The preceding generation passed through the trial of the Civil War and emerged, sobered and strengthened, ready for the development of this continent. When Bleriot crossed the Channel seven years ago he destroyed the isolation of Britain without decreasing the insularity of the British; but two years ago the flame of a great sentiment consumed that insularity amid the smoke of battle and beckoned the peoples overseas with a light of enthusiasm that is one of the fine things in a pentecostal calamity. Can we learn the lesson without undergoing the experience? Then let us watch Europe in deep seriousness and with intense sympathy. The great belligerents on both sides are fighting for big ideas; it is for us at least to respect the sacrifice of industrial welfare and personal comfort, nay, life itself, ungrudgingly, for something that is not measured in dollars and cents. Let us not,

like the Pharisee, give thanks that we are not as other men are. The self-complacency that congratulates the American people on being outside the dread conflict is not in the least admirable. When we feel grateful for having escaped the horror, so far, let us thank the Atlantic, not our superiority over the gallant men who are dying for a principle and a purpose, and if we are spared to get the wider outlook from the high peak of success without being overwhelmed by the storm gathering on the farther summits let us learn that "the world view" begins at home: in the house, in the office; in the State; and in the United States. "That man's the best cosmopolite who loves his native country best" not merely proud of it, or boastful concerning it, but willing to surrender his comfort, his property, even his life, for it. The young man who wants to "have the world view" had better begin by being a good American before he ventures to sigh for new worlds to conquer. The first is no inconsiderable achievement, particularly in these days when hyphens have provoked a political appendicitis that threatens to require a surgical operation.

Leaving thin ice and proceeding on firm ground, it is a noteworthy fact that the War has stimulated enquiry in new directions and furnished information of an unexpected kind. The movement of Russian troops, for example, whether the mythical passage through Scotland or the recent landing at Marseilles, has made most of us better informed concerning the geography of a country that is 7000 miles in extent from east to west. We have learned that a people of 170 millions has no ice-free port, that Archangel in the White Sea, facing the Arctic, has been made open to navigation a few months longer by the use of a Canadian ice-breaker, and that recently a new port and railway terminal has been established at Alexandrovsk, or Katerina, on the estuary of the Luta river, on the coast of Lapland, just round the corner from the northern end of Norway, where a warm current from the Atlantic ensures open water throughout the year. Again, take the activities of the sea-raiders, from the *Emden* to the *Moewe*; everybody has had to consult the atlas in order to follow their movements, learning incidentally what trade-routes were affected and how coaling-stations are distributed over the seven seas. Even more informing has been the interference with trade in various commodities, causing us to learn the sources of supply of many things in common use. More particularly, the War has been the means of causing the average man to become interested in mineral products, the supply of which has been stopped or rendered abnormally expensive. The man in the street has taken an interest in the production of the metals and the technical man has studied the statistics of production with keener insight than heretofore. All of this has enlarged the mental horizon of the ordinary citizen and given him a little of that world view that distinguishes the man of education. For real education, by drawing out the better faculties, tends always to a larger sympathy and a better understanding. The time will come when the thickness, not the color, of the human skin will be deemed decisive, when the spread of a common language will enable men of diverse countries to discover that the barriers of prejudice are lowered by the ability to exchange ideas; when at last there will be developed a world citizen, as able to reconcile loyalty to his native land with goodwill to other countries as he is now able to combine civic duty with devotion to home.

Mining Geologist

Should a special degree be created for proficiency in geology? This question is now being ventilated in the pages of *Economic Geology*. In its current issue we find letters on the subject from nine engineers and geologists competent to express an opinion. Mr. Robert Peele thinks that a good training in mining engineering is essential to a man intending to specialize in mining geology. Mr. F. Leslie Ransome remarks that "academic degrees in this country have very little significance," because they do not indicate the institutions by which they have been conferred. Mr. Ralph Arnold is heartily in favor of granting a degree in mining geology, but not until the candidate has obtained a bachelor's degree in geology, plus one year of practical experience. Mr. E. G. Spilsbury points to the lack of uniformity in geological curricula and agrees with Professor Peele that the proposed degree should involve a post-graduate course after mining engineering. Dr. A. R. Ledoux suggests 'economic geologist' as a proper title, to be granted after post-graduate study. Mr. J. Parke Channing recognizes the need for specialization and is not unfavorable to the granting of a special diploma, but he realizes that the multiplicity of degrees in technology has become confusing. Finally, Mr. R. V. Norris considers that the description 'mining geologist' has been so often abused by incompetent men that it may prove dangerous to use it as a university degree. These opinions have their personal interest and taken together they are likely to be representative of professional attitude on the matter. It would seem essential that any such degree should be supplementary to training and experience in mining engineering. We have 'geologists' and 'mining engineers;' if we are to have 'mining geologists' as specialists endorsed academicaly, they must combine the training of both their predecessors in professional practice. No geologist is competent to advise upon the exploratory or development work of a mine unless he is familiar with the technique of mining. Lack of such familiarity has caused many geologists to make sad blunders. Mining geology is essentially economic, that is, it deals with the making of money by the exploitation of ore deposits: therefore a familiarity with the operations of mining and metallurgy, more particularly the cost of such operations, is a pre-requisite to advice that is worth having. The geologist studies rocks and minerals, their origin and relations; the mining geologist applies that study to the business of making money by extracting metals out of those rocks and minerals. To do that he must understand mining engineering.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

Cyanidation of Flotation Concentrate

The Editor:

Sir—In your discussion department of the 11th inst., I note an answer by Mr. E. M. Hamilton to your question as to whether flotation concentrate could be successfully cyanided. While a refugee in the States two years ago, I did some work along that line, and am at present engaged in a similar investigation with the ores of the El Oro district.

Herewith is a brief summary of some tests made on a low-grade ore from Lower California. The ore in question carried only 0.16 oz. gold and 0.25 oz. silver; the silver content being so low, I took no account of it in the concentration tests. Quite a number of small half-kilo tests were run with an M. S. machine to obtain sufficient concentrate for the cyanide work. The first composite concentrate obtained carried exactly one ounce of gold. This sample, ground to 200-mesh, was then treated with a 0.11% cyanide solution containing 20 lb. lime and 200 grams lead acetate per ton of ore. The ratio of solid to liquid was 1:3. Time of treatment was 91 hours. After 24 hours the cyanide had dropped so low that it was necessary to make up to strength again. The total consumption of cyanide was 20 lb. per ton of ore. Total lime consumption, 40 lb. approximately. The final residue assayed 0.03 oz. gold. Extraction, 97%.

The excessive consumption of cyanide was undoubtedly due to the presence of flotation-oil, although the amount of oil used in any test did not exceed one pound per ton.

Another test was run with the idea of removing the oil before cyanidation by a preliminary treatment with caustic soda. The composite concentrate in this case carried 0.50 oz. gold and was ground to 200-mesh and then treated with caustic soda solution (0.49% NaOH Solid: Liquid, 1:3). After 20 hours contact the effluent liquor carried 0.34% NaOH which represented a consumption of 9 lb. per ton of ore. The pulp was then charged to a small filter-press, the liquor was filtered off and the cake given a wash with clean water. The pulp was then charged to an agitator-jar and cyanide solution added: 0.15% KCN, 20 lb. CaO per ton of ore. The total consumption of cyanide in terms of KCN was 3.6 lb. per ton of ore. The residue assayed 0.07 oz. gold. Extraction, 86.1%. The lower extraction was possibly due to the fact that no lead acetate was added and that the time of agitation was so short as 24 hours. Nevertheless, it proves that the oil can be removed economically if it is found to act as a cyanicide, as in the first experiment. A table-concentrate of this same ore had about the same cyanide consumption as the flotation concentrate after preliminary treatment with caustic soda.

In some cases, I believe, a very light calcination of such a concentrate would be sufficient to drive off the excess of any volatile oils that might be cyanicides. This step would be quite inexpensive, and cyanidation could afterward proceed in the usual manner.

Although it may be found in some instances that the extraction is not affected by leaving the oil in the ore, still I believe it may cause other serious difficulties when the amount of oil has increased sufficiently by re-use of the cyanide solution. I have particular reference to the difficulties that may arise in the precipitation end of the plant. This opinion is based on an experience obtained here, when, due to accidental causes, we had a large excess of oil in our gold-precipitation circuit.

It seems that a combination of oil, alkali, cyanide, and zinc-dust bring about the precipitation of a gelatinous compound that clogs the zinc-press cloths, causing the pressure to rise to dangerous limits. This occurred whenever we used air for displacing solution in the slime-presses. We found that the air carried considerable oil—a lard oil in the one case investigated. On the surface of the gold-tanks an oily scum was always present and the solutions never appeared very clear when using the air as previously mentioned.

The oily compound that formed in the zinc-presses was removed with iron scrapers in order to make the cloths permeable again. The following is an analysis of this compound removed from the cloths when we were having considerable trouble.

	%
Hydrocarbons, by ignition	88.95
Residue ash (by difference)	11.05
Fe	0.16
Zn	4.82
CaO	5.00
Insoluble	0.70

Au, 72.5 grams; Ag, 377.5 grams.

A qualitative examination of a gummy substance similar to the above showed a small amount of oil, and it contained lime, zinc oxide, small amount of lead, amorphous slime, and precipitate.

These two substances appear to be crude soaps, made by the saponification of the oils by the caustic alkali. I called the compound a 'crude soap' for lack of a better word. Raising the strength of the cyanide solution tended to lessen the trouble, but did not wholly stop it.

The above case is cited to show what might be expected to happen if certain flotation oils are not removed before cyanidation takes place. The same reaction would take place in a zinc box, no doubt, for zinc is zinc whether thread or dust. A nasty oily precipitate might finally accumulate, causing a decrease in flow and a drop in the precipitative efficiency of the zinc.

PAUL W. AVERY.

[We invite further correspondence on this important subject.—EDITOR.]

The Metric System

The Editor:

Sir—In your editorial note on page 538 you ask your readers to consider a new unit of measurement, which is to be 60 inches long, to be called *ur* and to be adopted by the Pan-American countries. Nothing is said as to the size or names of the standards for either weight or volume.

In response to your request, I have considered the above suggestion and find it to be absurd and superfluous, and I wish to record my protest against such an erratic proposal. What the world needs at present is the universal adoption of the metric system, now used by all the so-called civilized nations with the exception of the English-speaking countries and Russia. The metric system has been legalized in the United States since 1866 but has never come into extensive use except in chemical laboratories and assay-offices. An effort is now being made to hasten the inevitable adoption of the system. This effort is the Dillon bill, now before the House Committee on Coinage, Weights, and Measures; this bill declares that in four years from its passage the metric system shall be the sole standard of weights and measures in the United States and Section 4 of the bill states:

"That any person, corporation, company, society, or association who shall use, or offer and attempt to use, in any industrial or commercial transaction in the sale or purchase of any commodity any other weights and measures than those of the metric system on or after July 1, 1924, shall be guilty of a misdemeanor, and upon conviction thereof in any court of competent jurisdiction shall be punished by a fine of not more than $500 or by imprisonment for not more than three months, or by both such fine and imprisonment."

In the opinion of those engineers whom I have consulted the passage of the Dillon bill will prove of great benefit to our trade and industry and will relieve our children of the painful task of learning a confusion of tables. Dr. J. V. Collins, of Wisconsin estimates that the annual saving to the country by the introduction of the metric system will be $315,000,000. Probably this is an excessive valuation of the saving, but it is certain that the saving will be very great and the need for the adoption of the metric system is only equaled by the need for the reform of our chaotic spelling.

Therefore all engineers should lend their support to the Dillon bill. The change from our present system to the metric will cause some trouble, but that will be speedily forgotten as soon as the system is in force. This was the experience in Germany, where its compulsory adoption was strenuously combated and where the newspapers were filled with violent articles against it. But after a few months all were satisfied and the same result will be reached here.

And I hope that you and your readers will not be led astray by specious arguments as to the fancied superiority of the duodecimal system in practical life, but will work for the speedy adoption of the metric system and to that end will write to your congressmen and senators in favor of the Dillon bill.

W. H. SHOCKLEY.

Palo Alto, April 16.

Treatment of Slime-Residue

The Editor:

Sir—In your issue of January 1, Mr. W. Motherwell refers to the tipping of slime-residue on the sand-dump at the Occidental mine, near Cobar, New South Wales.

The dump was about 50 ft. high, and the prevailing wind drove the sand in the direction of the leaching-plant, encroaching to such an extent that it was found necessary to remove it repeatedly.

With the erection of the Moore filter-plant in 1905, the slime-residue was tipped around the edge of the dump, and practically stopped further encroachment. At this time water was not available for discharging this residue, but when the mine had reached a greater depth sufficient water was supplied from this source to enable a pumping scheme to be adopted. The Moore filter discharged its load into a hopper, which fed the residue onto a screen, made of parallel ¾-inch bars one inch apart. Below this screen was a cone-bottomed tank, to which the suction of a 3-inch Morris centrifugal pump was attached. The delivery-pipe, at a point three feet above the screen, had a T-piece fitted. Into this was screwed a short piece of pipe, with a 3-inch plug-cock and bend attached delivering onto the screen. To operate the mixer, the tank was half-filled with water, and the pump started with the 3-inch cock wide open. The slime-residue was allowed to slide onto the bars, where it was cut up, and forced through the screen. In a few minutes the whole charge was disintegrated successfully. The cock was then closed and the residue pumped to the dump.

A. J. CHAPPLE.

Canbelego, N. S. W., March 23.

RAILWAY LINES to the extent of 1000 miles are owned and operated by Phelps, Dodge & Co. The El Paso & Southwestern Ry. connecting the Bisbee district of Arizona with El Paso, and including a branch to the Mexican mines of Phelps, Dodge & Co., is stated to be one of the best constructed and operated railways in North America, with modern locomotives and cars. The El Paso & Southwestern Ry. has been but little affected by the recent border troubles.

Origin of Nitrate

By Courtenay De Kalb

THEORIES advanced by investigators to account for the origin of sodium nitrate in Chile were reviewed in the Mining and Scientific Press (June 13, 1914) by Lester W. Strauss, following discussions of this problem in a series of papers published some years earlier in the Boletín de la Sociedad de Minería de Chile. These theories include (a) the action of static electricity liberating oxides of nitrogen, forming nitric acid in contact with the moisture of the air; (b) accumulation of nitrates in soil through the action of certain micro-organisms; (c) decomposition of sea-weed during an earlier marine epoch of the inter-Andean valley; (d) oxidation of nitrogen in vegetal matter in the soil, a calcium nitrate being first formed that, reacting with sodium chloride, would produce sodium nitrate, setting calcium chloride free; (e) æolian deposits of guano dust, reacting with the soil constituents; (f) nitrogen-bearing volcanic waters. The outcome of the discussion, as Mr. Strauss says, is to leave the ultimate source of the nitrogen an unsolved problem.

The physical conditions in Chile consist of a coastal range about 5000 ft. high, between which and the high wall of the Andes lies an elevated plateau, sloping from the Andes toward the Coast range. The region is practically free from rains. It is recognized that a season of heavy precipitation would leach and ruin a great part of the nitrate field. Mist and fog, however, are of nightly occurrence during the winter months, and it is observed that some connection exists between these mists and the nitrate deposits. Whether this is an accidental or a genetic relationship is still a moot point. It should be noted that enough rain falls to produce, in the course of centuries, a downward migration of any salts formed along the higher slopes, but not enough to leach the lower soils. The tendency would thus be gradually to enrich the deposits along the western or lower side of the plateau or pampa.

A well known occurrence of nitrates near Rodeo, in south-western New Mexico, offers a hint of another probable mode of origin for the Chilean deposits. If the rain-fall at Rodeo were less than one inch per annum, and were confined chiefly to precipitation upon the mountain ranges bounding the Rodeo valley, it is practically certain that commercial deposits of nitrate would exist in this region. The rain-fall is above five inches, however, and the result is a valley possessing soils of extraordinary nitrogen content, famous for the production of beans by dry-farming.

The Rodeo valley trends north and south, bounded on the west by the lofty Chiricahui mountains, a range of igneous and metamorphic rocks, while on the east it is flanked by the Peloncillo range, consisting of rhyolite tuffs, overlaid by thick rhyolite effusives. Block-faulting on a splendid scale has lifted the tuffs, with their lava-caps, into great scarps which have been eroded into fantastic architectural shapes. In places later faulting has tilted the beds so that the flow-planes of the lava-capping stand in a nearly vertical position.

The nitrate occurs as an incrustation upon the faces of the cliffs of tuff. It is more abundant where the rock has been recessed by æolian wear, or protected by overhanging cornices of the sculptured surface, but it is present in some degree wherever the tuff is exposed. It forms in the parting-seams of the rock, layer after layer being found to a depth of many inches. In places the enriched seams extend to a depth of several feet. The highest concentrations do not exceed 6% of sodium and potassium nitrate, and for the most part the outer shell will not yield over 1.5%.

In the 'washes' along the drainage-line leading from the Peloncillo range into the valley the detritus shows cemented zones gray with salt that generally carries from 1% to 2.5% of nitrate. Thus the migration of the salt toward the valley is conspicuous.

Very noticeable is the fact that where the tuff beds with their lava-caps have been faulted into a vertical position the amount of nitrate formed on the surface of the tuff is insignificant. The richer incrustations occur where the beds of tuff dip slightly toward the valley. It is also interesting to observe that the lava-capping possesses a rudely columnar structure, so that the precipitation to a large extent finds its way through the jointure into the underlying tuffs, which consequently are always moist at a depth of a few inches from the surface. Where the tuff forms the crest of the mountain no such phenomenon is seen, the rocks being peculiarly free from moisture.

The evidence is abundant that the nitrate is formed in the tuff, and is exuded toward the surface by seepage, which is mainly capillary.

The alteration of the tuff has been extreme, so that fresh specimens are difficult to obtain. Kaolinization has gone forward, with the formation of many hydrous aluminum silicates. Also the amount of magnetite in the altered tuff is most noteworthy, which may be connected with the series of reactions resulting in the generation of the nitrate.

Tuffs represent a product of volcanic outburst of explosive violence. At Mt. Pelée the inflammable gases in the *nuée ardent* were held in the ash-cloud, which as a whole possessed sufficient weight, despite its high temperature, to roll down to the sea, the gases lighter than air being held in this mantle of lapilli, and prevented by interference of particles from diffusing at once into the

atmosphere. It would seem not improbable that extraordinary outbursts of lapilli, producing widely extended deposits of tuffs, must carry down large quantities of gases, both 'entrained,' to borrow a term from the steam engineer, and perhaps also occluded in the particles themselves. The latter, as shown by M. Le Brun,* would be held tenaciously until liberated by alteration of the mineral constituents of the rock. In either case the gases would be evolved slowly, though long periods of time might be required for thick and deeply buried tuffs to part with their primary gas-content. Where hydrogen constituted part of the occluded gas the conditions would favor the direct formation of NH_3 in contact with the nitrogen of the air. Also nitrogen and hydrogen in the volcanic emanation might form ammonia within the tuff itself, which would oxidize to nitric acid either by contact with dissolved oxygen in later infiltrating waters, or on being brought by seepage into contact with the oxygen of the air.

Finally, to revert to a possible rôle of magnetite in the genesis of nitrates, attention may be called to the production of this compound from the ferrous iron in decomposing silicates, in accordance with the following reversible reaction:

$$3FeO + H_2O \rightleftharpoons Fe_3O_4 + 2H$$

This reaction is uninfluenced by changes of pressure, the direction of the reaction being determined by variations of temperature. The production of Fe_3O_4 being strongly exothermic, the action would soon be halted. Lowering of the temperature favors the formation of the magnetite. Nascent hydrogen, evolved in this reaction, would unite directly with nitrogen, present from dissolved air in infiltrating water, or as primary gas-content:

$$3H_2 + 2N = 2NH_3$$

Oxygen, similarly present in solution, would yield:

$$2NH_3 + 8O = 2HNO_3 + 2H_2O$$

Free alkali, present from processes of alteration in the rock, would then produce:

$$2HNO_3 + \begin{Bmatrix} K_2O \text{ or} \\ Na_2O \end{Bmatrix} = 2 \begin{Bmatrix} KNO_3 \text{ or} \\ NaNO_3 \end{Bmatrix} + H_2O$$

A well-known German process for the commercial fixation of nitrogen, developed within the last few years, depends upon the direct combination of nascent hydrogen with nitrogen to form ammonia.

LARGE numbers of English sovereigns (£1 or $4.80) are being melted throughout India to make good the falling-off in imports of gold bullion. The effect of this has been to create a decrease in the circulating medium which may have to be made good by the end of the year by the increased coinage of rupees (28c.). It is estimated that about 20,000 to 25,000 sovereigns are being melted in India every day for the last 18 months. This must have created a fairly large gap in the amount of money in circulation. This constant melting of sovereigns has told on the supply of this coin.

Rapid Assay of Lead

By Gregory Torossian

*The following method for the approximate quantitative determination of lead may be of value to metallurgists, mining engineers, prospectors, and others who have occasion to estimate quickly and with reasonable accuracy the lead content of certain lead compounds and minerals. The method is based on the reduction of lead compounds by nascent hydrogen.

An aluminum plate 2 in. wide, 5 in. long, and 0.03 in. thick is used. About ½ in. from each end of the plate concave cups are formed by placing the plate over one of the thumb-holes of a crucible-tong, or over a suitable ring, and striking it with a pestle. The diameter of the cup need not be more than 1 in. and the depth $\frac{3}{8}$ in. Before using, the aluminum plate is rubbed with emery-paper or sand so as to clean the surface from the aluminum oxide coating that hinders the action of acids. Each cup will serve for 15 determinations.

From 0.15 to 0.2 gram of the finely powdered sample is placed in the cup on the aluminum plate (it may be weighed directly on the plate in the cup), and moistened with a drop or two of dilute (1:3) hydrochloric acid. More acid is added, drop by drop, until its action on the aluminum is well started. The sample is subjected to this treatment for several seconds, or until the original color of the sample almost disappears or is changed markedly. By this time the sample becomes spongy, may be turned over by a pointed glass rod or gently stirred and more acid is added drop by drop, if necessary. After a minute or two the contents of the cup are stirred with a pointed glass rod for 5 min., or until all indications point to the completion of the reaction. In the case of lead sulphide the fact that sulphuretted hydrogen is no longer evolved is a good indication for the end of reaction. With colored lead compounds the disappearance of the color is indicative that the reduction is over. In my experiments the reductions took 5 to 10 minutes.

When the reduction is complete, a little pure water is added to the cup and after gentle stirring the liquor from the cup is decanted: this operation is repeated 4 or 5 times, or until the wash water shows no acid reaction (litmus test or 'tongue touch'). Now the spongy metallic lead in the cup is pressed together with a glass rod so as to make it solid and compact, then a filter-paper is pressed over the lead to dry it as completely as possible. Finally, one drop of water is placed near the cup on the plate, which is now warmed above a small flame or a lighted match, or any convenient small source of heat until the water is evaporated; this also dries the lead metal in the cup. The dried lead is now detached from the plate by a pocket knife and weighed, and the percentage of lead is calculated on the original sample.

This method is simple and quick, and sufficiently accurate to be of value in many instances of rapid estimation of lead in minerals and compounds.

*Abstract from *Jour. of Ind. and Eng. Chem.*, April, 1916.

Surficial Indications of Copper—I

By Frank H. Probert

BIG OAKS from little acorns grow, so too all mines were at one time the merest prospects with nothing but the outcrop as Nature's advertisement of her hidden treasure. Inasmuch as the outcrop is the surface expression of an orebody, a correct understanding of the significance of surficial signs is of paramount importance in the search for the mines.

At the Washington meeting of the American Institute of Mining Engineers, in February, 1900, the absorbing topic of secondary enrichment of ore deposits was presented for discussion. It has been discussed ever since. The literature of the subject has assumed library proportions and still there is, and must be, a wide diversity of opinion among equally competent men as to the sequence of sulphides in particular. In the effort to fathom these deep problems, higher horizons have been overlooked. Are we not trying to look from the bottom up rather than from the top down? Is it not high time that the outcrops of the veins and the surface indications of the enormous disseminated deposits were carefully investigated and critically studied? Mineralized districts, productive mines and prospects in all stages of development have been severally described from time to time, either in the publications of governmental bureaus, the transactions of learned societies, or in the columns of technical journals, but few attempts have thus far been made to assemble the scrappy and widely scattered information and from it develop, if possible, some helpful hints to guide the prospector's pick and enlighten the engineer in the examination of undeveloped properties.

The history of the past is the prophecy of the future: beautiful theories are often killed by ugly facts; analogy is a dangerous weapon in the hands of the incompetent; nevertheless, the application of knowledge acquired, not from textbooks, but from the school of experience, can alone be the guide to fresh discoveries.

I am prompted and emboldened to write on this subject of surface signs by the many requests I have received since lecturing to the mining students of the University of California, for a transcript of my notes. This implies a lack of systematized study of the subject, or rather, an awakening to the appreciation of the importance of the outcrop as the sign-post to direct the miner where to dig. I claim no originality or finality in the presentation of my notes; I have culled liberally from the technical literature on the subject and acknowledge indebtedness to many engineers and publications. Direct recognition of their work in foot-notes would make this series of articles needlessly cumbersome. I would however express my appreciation of the work of W. H. Emmons in piecing together pertinent information on the subject of secondary enrichment and presenting it as Bulletin 529 of the United States Geological Survey. This is to be supplemented by Bull. 625 now in the press. I commend it to all those interested in the study of outcrops.

The results of the exhaustive work of the 'Secondary Enrichment Commission,' under the direction of L. C. Graton, will be awaited with keen interest, for in that monograph the physical and chemical forces combining to produce commercial orebodies will be competently discussed.

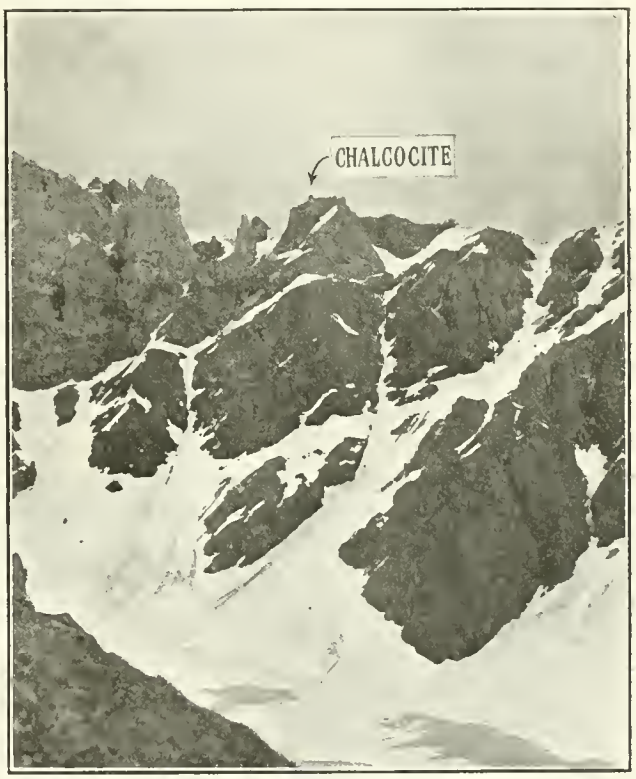

FIG. 8. OUTCROP OF THE BONANZA OREBODY OF THE KENNECOTT COPPER MINE, ALASKA.

I submit the following data, not with any idea of anticipating the views of others, but in the hope that a lively discussion of the subject will ensue, so that the profession at large may be benefited. I maintain that the study of surface indications is of the greatest importance and that it is perhaps a greater accomplishment to be able to anticipate, by virtue of correct diagnosis, the birth of a mine than to dissect the tissues of the internal organs of a healthy productive mine and establish their relationships.

It is imperative that the examination of new districts must be approached with an open mind. Many a good

district has been turned down because of a 'hunch,' an involuntary preconception that this or that is N. G. or O.K. It is surprising what an effect a tiresome trip, poor accommodations, an unfriendly greeting, a sick stomach, or other unfavorable factor, has on the prospective value of an ore deposit. Again, many an attractive prospect has been hopelessly spoiled by a little digging. It is advisable to attack new problems with the hope that they will justify endorsement—equally necessary to be a Missourian. Theories must be tested by analytical observation and conclusions built by synthetic reasoning.

Before going into the discussion of the life history of the outcrop, it is advisable to outline the conditions under which mineral deposits are formed and the areas most favorable for their surface expression.

Prolonged and intermittent volcanism is most favorable to the formation of ore deposits. Igneous rocks are enormous reservoirs of energy and the vapors from intrusives are pre-eminently favorable to chemical reactions. The distribution of mining districts can only be explained by the distribution of igneous rocks intruded under circumstances favorable to vein formation. Successive intrusions of igneous rocks may cause cumulative mineralization, or bring about such changes in the original mineralized rock as tend toward concentration or enrichment. The emanations, gaseous or aqueous, from one cooling magma, may develop certain minerals, such as pyrite or some other metallic sulphide, which will act as a nucleus of crystallization or as a precipitant for the mineral vapors from later volcanics. In the Ray district, Arizona, the latest intrusive rock of economic importance is granite-porphyry, cutting both the schist and diabase. Both intrusives are mineralized and in places so enriched by later processes as to constitute ore. S. F. Emmons attributed the Cananea deposits to the influence of three distinct eruptives.

Most of the copper deposits are genetically related, primarily, to either an acid-porphyry or monzonite, or to a more basic diabase.

American geologists assert that the copper mines of North America occur in greatly decomposed altered acid-porphyries, whereas, there is a marked tendency in Europe to affirm an intimate dependence on basic rocks. The presence of copper in small quantity in most ferro-magnesian rocks is definitely established, especially in diabase. This is instanced in the Lake Superior region, in New Jersey, Virginia, and in the Globe district of Arizona. In Chile the silver-copper veins occur in basic plagioclase-augite rocks. The large low-grade deposits of Bingham, Metcalf, Burro Mountain, Ely, and Chino, show a persistent connection with monzonite rocks.

The original deposits formed directly from molten magmas are seldom of commercial value. Nearly all the workable orebodies are the result of concentration and enrichment brought about by the agency of meteoric water, often repeated.

Von Cotta stated that "ore deposits are in a general way formed in regions of older rocks." A few copper deposits are of pre-Cambrian age, but by far the larger number are post-Palæozoic and were formed during early Tertiary time. This was a period of great volcanic activity, of dismal uplift, mountain building, adjustment of the earth's crust, with induced faulting, folding, sheering, and fracturing. It changed the topography and initiated new physiographic conditions.

There are several types of copper deposits: fissure veins, contact metamorphic deposits, the so called 'porphyry coppers,' or low-grade masses of disseminated mineral, magmatic deposits, replacements, and others. Each has its peculiar characteristics of surface expression, of metal and rock associations. Fissure-veins occupy faults or fractures in the earth's crust caused by the adjustment to and equalization of internal forces. The nature of the enclosing rock frequently influences the outcrop. Faults wholly in limestone have a tendency to heal, like a wound, leaving a more or less inconspicuous scar on the surface. Quartzite faults show as ragged brecciated outcrops, weathering in sharp relief, while those in igneous rocks may or may not be prominent (Fig. 1). As a rule, the sedimentary are more resistant to erosion than the igneous rocks, except when the latter have been shattered and silicified. Veins are indicated at the surface either by ridges or depressions, according to the relative hardness, and consequent resistance to erosion of vein-filling and wall-rock. Few veins apex with the little end up, and inasmuch as the mineral content is frequently concentrated within the comparatively narrow confines of the fracture, the zone of oxidation, in its surface aspects, is likely to be quite conspicuous. Limonitic and hematitic outcrops are common (Fig. 2). We must not, however, attach too much significance to the attractive coloring; a little copper may stain a wide area, and a little iron a whole mountain. Many worthless veins show large gossans. The great veins of Australia, Butte, and Morenci have no iron-capping to speak of, but are indicated by silicified and disintegrated rock. The width of a gossan is apt to be greater than the vein itself on account of the permeation of oxidizing waters into the wall-rock.

Contact metamorphic deposits are generally found in stratified rocks, and were formed under the influence of invading masses of deep-seated volcanic eruptives. The most important criterion is their mineralogic composition, since they present a distinctive mineral grouping. Garnet, epidote, and wollastonite are indicative of contact metasomatism. There is generally a complete change of form and structure due to contact and chemical metamorphism; the rocks are re-crystallized and intensely resistant. Areas of limestone, altered by the fluids escaping from intruded igneous magmas, are particularly favorable to ore deposits of this type. At Morenci, Metcalf, Bisbee, Silverbell, all in Arizona, at Cananea, Mexico, at Mackay, Idaho, and at Bingham, Utah, large contact metamorphic deposits have been successfully exploited. At Bisbee, the garnet area is but sparingly developed, and the characteristic outcrops of this type are not conspicuous, but in the other districts mentioned, the peculiar surface exposures cannot fail to attract attention. Acid porphyries were forced into the limestones and shales. The vapors from the cooling mass

changed the sediments to a compact, hard, relatively impervious rock mass of garnetiferous epidote, carrying metallic sulphides. Later the porphyry was subjected to contractional strains, which permitted of the release of further magmatic emanations. They mineralized both the intruded and intrusives with low-grade disseminated ore, accompanied by intense alteration of the

FIG. 1. FAULT SCARP, OLD DOMINION VEIN, GLOBE, ARIZONA.

porphyry. J. B. Umpleby is making an exhaustive study of the contact metamorphic deposits of the United States. I gather from conversational remarks that he recognizes two distinct periods of mineralization, the first of the nature of marmorization and re-crystallization of the intruded sediments with development of complex silicates, the second that of metallization due to the escape of metallic vapors from the cooling magmas. The garnetiferous limestones are peculiarly resistant to weathering and their outcrops appear as iron-stained rugged masses above the eroded and decomposed porphyry (Fig. 3). Secondary enrichment of sulphides is uncommon in orebodies of this type, although surface concentration of silicates, carbonates, and oxides of copper are found. The copper in the oxidized caps of this type of deposit seems to be locked up as chrysocolla, 'copper pitch,' or allied salts. It does not migrate to deeper zones. This may be due to the texture of the highly altered sediments. Such sulphides as do exist are nearly always primary, but most of the available ore is of the direct smelting oxidized class. The orebodies are not related to systems of faults or fissures; the rocks are tough and do not fracture readily; moreover, because of the calcite or lime content, oxygenated waters are robbed of the contained copper. Chalcopyrite or cupriferous pyrite are the primary minerals of greatest economic importance that by oxidizing processes have formed ore. While all these districts are notable because of these contact metamorphic deposits, the bulk of the ore mined comes from the porphyry areas and is of the disseminated enriched type.

The 'porphyry coppers' constitute a type that came into public favor about ten years ago. The success of the Utah Copper Co. stimulated a search for other deposits of the same type the world over. Chino, Ray, Ajo, Miami, Inspiration, Ely, and the Siberian deposits have all been developed since that time and today contribute the bulk of the world's copper supply.

With the development of these enormous deposits, mining and milling methods have changed and the science of the mechanics of mining has taken a big step forward. Steam-shovel and caving methods have been elaborated successfully, and wet concentration is now followed by flotation.

The low-grade disseminated deposits are the result of secondary enrichment of lean sulphides scattered throughout highly-altered porphyritic or schistose rocks. Weathering, erosion, and oxidation have combined to concentrate the metal into definite horizons and the ore deposits may represent the net results of two or three generations of enriching processes (Fig. 4 and 5).

The deep-seated magmatic deposits seldom find expression on the surface, so that chances for oxidation and enrichment are remote. Blind veins have no outcrop: they may be blind because of faulting near the surface, or they may have been buried by later formations, but meteoric waters may have oxidized and enriched them before the time of the rupture or burial. At Jerome, Arizona, there is an overlying mantle of

FIG. 2. MASSIVE HEMATITE OUTCROP, BLACK HAWK VEIN, GLOBE, ARIZONA.

post-mineral sediments, several hundred feet thick, that effectually masks the presence of copper except where, by faulting and erosion, isolated exposures have resulted. Fully 90% of the surface located as mineral land is covered by rocks having no connection whatsoever with the ore deposits (Fig. 6).

Let us first consider briefly the Lake Superior lodes

and the copper deposits of the 'Red Beds' of the Trias and Permian. The Upper Peninsula has produced about 15% of the world's copper for many years, nor are the amygdaloid or conglomerate lodes exhausted. The average yield per ton of rock does not exceed 18 lb., but improved metallurgical practice is fast changing discarded waste from mine and mill into 'ore.' The Copper Range of Lake Superior has a northeasterly trend; it is 70 miles long and from three to six miles wide, in crescent shape. The ore is associated with basic igneous rocks, between 60 and 70% coming from the amygdaloid lodes. Mineral-laden waters have replaced certain beds in the uptilted conglomerates, forming orebodies persistent to great depths. The lodes are not characterized by conspicuous outcrops. The whole country has been base levelled by glaciation so that the present topography has no recognizable relation to the ore deposits. The surface is covered by drift or soil, so that an intimate knowledge of the local geology is essential to intelligent prospecting. Usually the amygdaloid weathers more rapidly than the trap-rock enclosing it; hence the infrequency of outcrop. The copper-bearing conglomerate beds are more resistant and occasionally show at surface. Such outcrops as have been found show slight carbonate and oxide stains, enveloping nuclei of native copper. The element of chance discovery has entered largely into the development of the Lake Superior copper mines.

The deposits of copper in certain sandstone beds of Triassic and Permian age have also added largely to the copper supply and, as developments both in the United States and South America show, are increasingly worthy of attention. They are widely distributed geographically; the most productive beds being at Mansfeld, in Germany, but similar deposits are found in the Ural region, Russia; in Alsace-Lorraine; at Corocoro in Bolivia; in the Appalachian system from Nova Scotia to New Jersey; in Texas, in New Mexico, and in many parts of the Colorado plateau from the Uncompahgre valley to the Grand Canyon. It is of importance to note that in no one of these deposits has any positive genetic connection been established between the copper beds and eruptive rocks.

Louis M. Richard, in describing the copper deposits in the 'Red Beds' of Texas, says: "The great linear extent of the exposures and natural outcrops, as compared with the narrow width, suggests that the arrangement of the deposits has been dependent upon the topography at the particular period in which the deposit was formed."[1] The surface is conspicuously altered by oxidation. The clays are stained a bluish-green. The ability of kaolinitic material to absorb copper from pregnant solutions will be referred to later, as the outcrop not infrequently exemplifies this condition. Richard states that "the copper is associated with carbonaceous matter, especially carbonized and fossilized wood, plant stems, and grasses." This confirms the observations made in the Perm district of Russia by W. H. Twelvetrees and Thomas Rickard, 40 years ago.[2] In the *kupferschiefer* of Mansfeld, distorted skeletons of fish have been entirely replaced by both native copper and silver. The general principles that govern the surface expression of nearly all other types of copper deposits are not found here, and intimate knowledge of the stratigraphic geology, coupled with chance discovery, must be relied upon to add to the further development of this type.

Before we can understand the complexities of copper outcrops, we must be conversant with the general structure of the earth's upper crust. The crust of the earth is divided into two zones, a zone of fracture and a zone of flowage. The division is based upon changed conditions of temperature and pressure with depth. Chemical reactions, which take place in a certain way under ordinary conditions of temperature and pressure in the zone of fracture, are reversed in the lower zone where high temperatures and great pressures prevail.

We are concerned only with the zone of fracture. The rocks contain many openings, major and minor faults, slips, cleavages, joints, areas of sheering and brecciation, and a maze of microscopic channels. They are porous and admit of the free circulation of meteoric waters. The chemical reactions that take place in this zone are governed by chemical affinity. The zone of fracture is subdivided into the belt of weathering and the belt of cementation, or, to use the terms as first intended, the zone of oxidation and secondary enrichment.

The belt of weathering extends from the surface to the level of ground-water. Its thickness is therefore very variable. The reactions that take place in this belt are those of hydration, oxidation, absorption of silica, and losses of material by leaching. It is a region of low pressures, low temperatures, and great porosity. The complex silicates and metallic sulphides are broken down into simpler compounds, from which, within the belt, they are rarely regenerated. In the belt of cementation, or in the ground-water zone, re-deposition rules. There is a marked contrast in the rock-mass above and below ground-water level. Below, the rocks are less porous, temperature and pressure increases, dehydration takes place, oxidation gives way to reduction, carbonates are decomposed, and silicates regenerated. The belts or zones cannot be rigorously delimited. They shade into and inter-penetrate each other.

In the upper zone, chemical reactions are exothermic and are accompanied by increase of volume. Physical forces, by the accumulation of sediments, may, in periods of geologic time, so bury the surface that it is subject to the conditions of the deeper zone. Again, the erosive factor may bring to the surface deep-seated rocks.

Water is the chief agent of chemical metamorphism. It moves freely in the upper crust, less freely below.

[1] *Economic Geology*, Vol. X, No. 7, December, 1915.

[2] For this note I am indebted to T. A. Rickard, who also states that he recalls clearly the fact of seeing, as a boy, the replacement of plant remains by copper in the Permian sandstone of the Kargalinsky mines, east of the Ural mountains, while, on the other hand, animal fossils apparently had not precipitated the copper from the permeating solutions.

In the belt of weathering there is a generous transfer of material, both mechanically and chemically, from place to place.

In the anatomy of the zone of oxidation, we are confronted with the work of physical and chemical forces, acting at times together, in many instances separately, but their effects are closely related, and the condition of the outcrop is dependent on the far-reaching influence of both. The present topography may be vastly different from that of the early days of a mineral deposit; the surface of the earth is always changing, and the forces that change the sky-line influence an orebody. Mineral deposits, particularly those of copper, generally find expression on the surface, either by striking coloring or topographic relief. Physical and chemical forces combine to denote, in some way or other, the presence of ore.

FIG. 5. LOWER PICTURE. SURFACE EXPRESSION OF RAY CONSOLIDATED OREBODY.

Copper deposits are characteristically confined to mountainous regions, either in the sections of marked relief today or in the remnants of former ridges, so that physiographic conditions and topographic details have a decided value as indicators of surface concentration.

H. Foster Bain has stated recently: "the physiographical history of a region in which an orebody is found frequently influences and often determines its character. This history must be read and interpreted if geology is to be of full service in the development of the deposits." Both the miner and the petrologist have at times lost sight of the fact that the study of ore deposits—their occurrence, form, and extent—is a complex problem requiring analysis from many viewpoints. Given a favorable receptacle, a likely structure, and the necessary minerals being present, the occurrence or non-occurrence of ore rich enough to ensure profit from working, is determined by the geological history. It is the recent geological history, which can be read in the surface of the land, that is usually a determining factor in economic exploitation of ore deposits. H. H. Knox and A. W. Stickney, at Kyshtim, and other careful observers elsewhere have called attention to the importance of a study of physiographic conditions to ore deposits. L. C. Graton, assisted by W. W. Atwood, is making elaborate investigations along these lines, whereas a number of observers have, perhaps, taken too much for granted in determining the true character of the chalcocite in the Bonanza mine of Alaska.

The climatic conditions, nature of the rocks, size of openings, and proximity to water determine the topography and influence erosion. Rapid changes of temperature cause uneven expansion and contraction of the upper part of the crust as a whole and of the individual constituents. Scaling, flaking, crumbling, and disintegration are the result. Extremes of heat and cold are potent factors. The expansion of water on freezing is a force sufficiently strong to split asunder the hardest rocks. A line of weakness once initiated may never heal, each succeeding frost makes it weaker, other planes of fracture develop, and soon boulder structure results (Fig. 7). Joints, cleavages, and bedding-planes will act in the same way; the rocks become porous and in consequence present larger surfaces for the more corrosive attacks of oxygenated or acid waters.

High temperature facilitates chemical change by heating the solutions, by increasing their solvent powers, by assisting vegetal growth; it hastens the decomposition of organic matter; it generates gases and furthers rock disintegration by the unequal expansion of component minerals. Heat promotes chemical action; freezing prevents solution. Horace V. Winchell has given[4] some interesting data on the relation of climate and latitude to bonanza ore. In commenting on the possibilities of the great North-west, he says: "the region generally looks more attractive to the prospector than to the student of economic geology." There are a few principles based upon chemical facts that have a universal application, and should be remembered in connection with the surface indications of mineral deposits, either now or formerly covered by great ice-sheets. There is a vast difference in the surface appearance and mineralization in different isotherms. As Winchell says, "Where the rocks are exposed in Northern latitudes, they are fresh, hard, and unoxidized. There are no superficial areas of kaolinization, no gossan, nor even iron-stained surface rocks. Even crevices or other minor structural details are rare. The accumulated débris left in the wake of glaciers and glacial streams will often show an abundance of unoxidized pyrite and associated sulphides. The surface of the country-rock is sometimes covered with a thin layer of iron and copper sulphides." This condition has many times warped the judgment of the prospector and extravagant stories of 'mountains of ore' have vanished into thin air almost before the first round of holes has been blasted. Even in favorable spots, where rocks are more permeable or filled with more readily oxidizable minerals, there is but a shallow envelope of enriched ore. For the most part, sulphide ore comes immediately to the surface and is seldom high-grade to any depth. These are broad generalizations, the result of observations made in British Columbia, Alaska, the ice-bound areas of Eastern and Central Canada, and the northern countries of Europe, particularly Norway and Sweden. Numerous exceptions, of course, exist. On passing from the Arctic regions of perpetual frost to the Equator, the zone of oxidation and enrichment seems to increase from zero thickness to one thousand feet or more. The destructive effect of the continental ice-sheet has not removed the dissipated oxidized ore deposits of the same magnitude as those occurring south of the ice planation.

In the temperate zone, deep superficial alteration and complete oxidation of vein-matter are common; they indicate high-grade ore below. Ore deposits are more abundant in the warm and temperate zones. They are not so likely to terminate suddenly or change rapidly in depth. It might be said that these are self-evident facts, but they are frequently forgotten when the opportunity arises to apply them in practice.

The higher latitudes are not only the coldest parts of the earth today, but the rocks, when exposed, show the glacial grooving of former geologic periods. The important orebodies of the northern countries are mostly of primary origin, although the famous Bonanza mine of the Chitina copper belt, Alaska, is a mass of chalcocite and bornite carrying silver, in a fractured limestone. Moffit and Maddren are non-committal in their diagnosis of the genesis of this ore, but imply that meteoric agencies have been at work. C. F. Tolman, Jr., in a recent paper,[5] describes the chalcocite as a replacement of original bornite, probably in part if not wholly due to meteoric agencies. This implies a long erosion interval, and possibly different climatic conditions than those which exist today (Fig. 8). In the Vermilion mine of Sudbury,

[3] *The Mining Magazine*, February, 1916, p. 72.

[4] *The Mining Magazine*, December, 1910, pp. 436, 438.

[5] Bulletin A. I. M. E., February, 1916.

Ontario, native copper, a final oxidation product of original chalcopyrite in this case, is found 900 ft. below the surface. The St. Eugene mine, in British Columbia, has secondary chalcocite. On the other hand, secondary sulphides are not always present in tropical regions. In the Sable Antelope mine of the Katue district, Rhodesia, only 13° south of the Equator, copper sulphides show at the surface and there is no superficial alteration.

It should, however, be remembered that great climatic changes have taken place in many regions and that temperatures have been by no means constant throughout geologic time. It does not follow that because processes of weathering are slow today that similar conditions existed always.

The effect of glaciation on outcrops of ore has been mechanical rather than chemical. Wholesale erosion of the rocks has ensued, mountains have been base-leveled, possibly a large part of the vein or deposit has been removed. A moving glacier, with its ammunition of entrained boulders, will destroy anything in its path. The base pressure is enormous on account of the weight of the superincumbent mass; hence, it is possible that in traveling over an orebody it will have a tendency to tear it apart, developing a series of fractures either in the mineral mass or in the encasing rock. Flowing water always escapes from the lip of a glacier; and it is probable that this water, charged with oxygen as it must be, seeps into these induced fissures and causes alteration to shallow depth.

R. W. Brock, when describing the copper deposits of

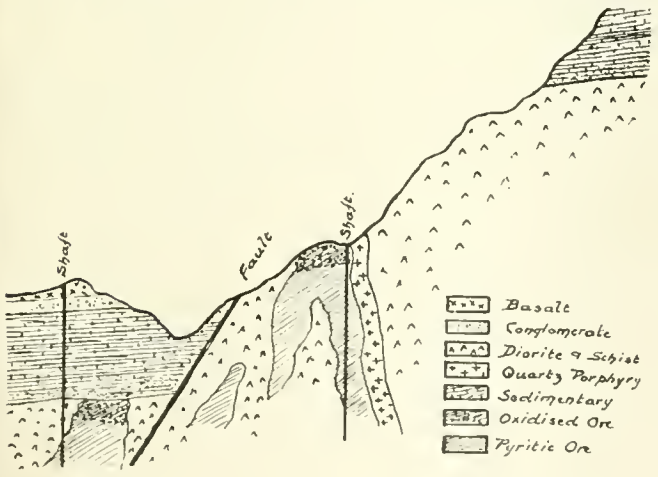

Fig. 6. Cross-section of the United Verde mine.

the Boundary Creek district of British Columbia, comments on the lack of oxidized material in the upper zone, but notes an important exception: at the King Solomon mine all phases of oxidation and enrichment are presented in the orebody, which occurs at the contact of porphyry and limestone. He attributes this to the local topography. The contact was a natural watercourse in former times.

The more recent the deposit, the less chance there is for extensive or great enrichment. The effect of oxidizing water is directly proportional to the time the deposit is exposed to weathering. If the rain-fall is slight, erosion is slight. The dew may bring about surficial oxidation in the main fractures of the rock, and local concentration of oxidized products. Where the country is widely shattered and altered, with mineralization along the fractures, or pyritic casts appear, and where there is moderate rain-fall, the chances are good for concentration in a relatively shallow zone. If the outcrops

Fig. 7. Typical boulder weathering of Butte granite. Pyritisation takes place along joints.

are strong and the rainfall is moderate, there is every probability of extensive concentration. If the contour is uneven and rain-fall is heavy, erosion will be rapid, oxidation shallow, and the zone quickly removed.

In dry sections with steep hill-slopes, the changes may be incomplete. A zone of mixed oxides and sulphide will form near the surface, but incomplete oxidation may be deep owing to the low water-level. In areas of much weathering, the re-distribution of the minerals will depend upon their solubility.

The leasing system as a means for working old mines has much to recommend it. There is a considerable difference between operating a mine by a corporation, including highly paid officials and overhead expense, and a leasing scheme where these functions are performed by one or two men. The mines of the Cobalt district, it is pointed out by the *Northern Miner*, are rapidly approaching the leasing stage. At Cripple Creek in Colorado, the 'split-check' leasing system, which has given such satisfactory results at large and small mines, provides that the company furnish the power and hoisting, while the lessee furnishes the labor, the net returns being divided equally.

Anthracite production of the United States in 1914 was 79,459,876 tons, averaging $2.32 per ton. Compared with 1914 this was a decrease of 2% and 1.9% respectively. Employment was given to 176,552 men, who produced 1.96 tons per man-day. These are final figures.

The Double Roasting Process at East Helena

By X

Preliminary Roasting on Sintering Machines

Condition of the Feed. The material to be roasted has been crushed and concentrated previously, so that the feed going to the Dwight-Lloyd machines ranges from ¼-inch size to the finest flotation-slime. It was found at East Helena that a more effective roast could be obtained by crushing through a ¼-inch screen, but this practice is not followed in the sampling-mills, because the decrease in size so hampered the mill-capacity that the management deemed it advisable to sacrifice better roasting conditions for larger output. After the screens are worn, the largest particle passing them is slightly greater than a quarter of an inch.

Mixing of Charge. The bedding method is adopted for the mixing of the Dwight-Lloyd charge. This is done in a series of bins situated in front of, and in close proximity to, the roaster-building. After the bins have been filled, according to calculated charges, the mix is loaded by hand into small tram-cars (capacity about 1½ tons of roast), which are pushed direct to the roasters. This system is costly and inefficient. In bedding the different constituents of the charge are not as thoroughly mixed as when handled by one of the several automatic mixing systems now in vogue. Of course, this bad feature is lessened to some extent by the dropping of the charge from one conveyor-belt to another, through the rolls and into the hoppers on its way to the roasting-machines. (At the present time the East Helena management is trying to secure an appropriation from the New York office for the installation of one of the mechanical-mixing systems.) Open or exposed bins, such as are necessary for bedding, are subject to weather conditions, making the present man-handling of the charge more cumbersome and expensive. The frozen chunks in the charge, composed mostly of vanner and flotation slimes, ranging in size from fine to pieces a foot in diameter, give considerable trouble in the roasting-department. In the first place, they do not permit of an even distribution of the slime-products throughout the charge, so that in the course of feeding the Dwight-Lloyds pieces of slime up to 1½-inch in diameter fall on the grates, and when the slime becomes slightly plastic, owing to thawing, large flattened pieces are fed to the sintering machines. Both of these conditions lean toward poor roasting inasmuch as the sulphur elimination is then cut down. At East Helena these difficulties have been partly overcome by passing the feed through a ½-inch trommel, the oversize from which is crushed in a jaw-hammer crusher through a ¾-inch screen. While this has proved most successful on frozen slime, I doubt if it will serve the purpose on wet, sticky, flotation-slime; and it is the general opinion around this plant that a dryer, preferably of the drum type, will have to be employed; after drying the charge should be mechanically mixed and the moisture content brought up to the desired point.

Moisture in Charge. This is not subject to close limitations; by some authorities 10% is said to give the best results, but at East Helena the moisture-content of the mixed charge rarely exceeds 8%. The upper limit should be when the material balls in the hand. Too little moisture leads to excessive dust in handling, leakage through the grates into the pit and wind-box, and too rapid combustion on the grates, producing a fused coating over the surface of the ore particles and an incomplete roast at the centre.

Sulphur in Charge. It is well established that the Dwight-Lloyd machines work most efficiently when the sulphur content is from 15 to 16%, but fairly good work can be obtained with sulphur as low as 11%. With rich lead mixtures the upper limits can only be reached by diluting with one or more of the lighter metallic sulphides, but this necessarily reduces the lead output of the machine. At East Helena it was found that the additional cost was no greater when roasting a charge carrying 15% sulphur down to 3½% than when reducing from 12% to 3½%. Where the percentage of sulphur is less than 12, a higher tonnage and smaller sulphur elimination is preferable, say from 11% to 5 or 6%. This is the fundamental working principle of the 'double roasting' process. At this smelter the first increase in capacity was from 110 tons per Dwight-Lloyd to 131 tons, and at the present writing to 230 tons. When the charge contains more than the maximum sulphur (16%) it should be diluted by adding non-roasting ores, preferably fine. The possibilities presented by the addition of slacked coal to the feed, to compensate for the lack of heat-units caused by too low a sulphur content, suggest an interesting experiment. The sulphur elimination and tonnage vary inversely, tonnage being heavily sacrificed to reach the lower sulphur proportion (3½ to 4%), especially if the original sulphur is less than 12%.

The Addition of Lime to the Dwight-Lloyd charge met with considerable opposition at first on the ground that on slaking it caused a disintegration of the sinter. In 'double roasting' this objection is of no importance, as the Dwight-Lloyd product is now crushed before treating in the Huntington & Heberlein pots and the breaking-up due to slaking only lessens the amount of crushing necessary. During former operations with these machines, when the tonnage was 110 to 131 tons per day, the average lime percentage was 2.6 on the feed, which was increased to 2.9% on the sinter. In the present-day practice the lime content of the feed has been raised to 8 or 9%, or 10 to 12% by bulk of limestone, with corre-

sponding increase of lime in the final sinter. This limestone is milled and crushed to ¼-inch size and mixed with the charge by bedding. Formerly the limestone was used as grate-dressing, a half-inch layer being placed between the grates and the ore-charge. While this method allowed the sinter to break free and clean from the grates it has been supplanted by mixing the limestone equally throughout the charge, as it affords more desirable blast-furnace conditions.

Lead in Charge. The average lead in the East Helena Dwight-Lloyd feed is 39 or 40%, increasing in the sinter to 41 or 42%. This lead is mainly in the form of sulphide (galena) with smaller amounts of carbonate and sulphate. There is little effort made to form sulphate of lead in this preliminary roast, because capacity with a fair reduction of sulphur is the main aim at this step in 'double roasting.' The principal difficulty encountered in roasting a charge high in galena is the premature fusing on the surface of the ore particles, thus preventing the roasting reaction from penetrating to the centre. Tonnage is favored by a high lead charge. Where the proportion of lead is 40% or over, the Dwight-Lloyd gases can be turned safely into the bag-house without endangering the bags. Enough lead oxide, together with small amounts of zinc oxide, are sufficient to neutralize most of the SO_3 gas.

Average Analysis of Feed. The following is the average analysis for the feed and sinter on the Dwight-Lloyd machines at East Helena during 1914 and 1915:

	SiO_2	Fe	S	Zn	CaO Former	CaO Present	Pb	Cu
	%	%	%	%	%	%	%	%
Feed ...	15.0	15.2	11.6	4.1	2.6	8 to 9	39.0	0.1
Sinter ..	16.8	17.2	4.5	4.0	2.9	8.5–9.5	41.7	0.4

At the present writing the initial sulphur in the charge is from 9 to 10% (at times even less), and the final sulphur for the Dwight-Lloyd sinter is from 5 to 6% for 'double roasting.'

Operation of Sintering Machines. The charge as trammed from the mixing-bins is dumped into a small hopper feeding directly to a conveyor-belt, which discharges into a ¼-inch trommel. The oversize from this trommel is passed through a crusher, of the jaw-hammer type, in order to reduce all oversize to ¼ inch (see statement under Mixing regarding handling of flotation-slime). The crushed feed is then conveyed, by a bucket-elevator discharging onto a conveyor-belt carrying a tripper, and the feed is thus distributed to the six storage-hoppers, as is required by the operating machines. Each Dwight-Lloyd receives its charge from individual hoppers, so constructed as to allow the coarser lumps in the mix to roll first on the grates, thus forming a bed for the fine and lessening the filling up and sticking of the charge to the grates.

The speed at which the grate moves is varied according to the tonnage and sulphur elimination desired. At 28 inches per minute the standard machine makes one revolution in 35 minutes. On Coeur d'Alene ores 16 inches per minute gives 131 tons, and 28 inches per minute gives 230 tons of sinter. These capacities are volumetric and are based on a 40% lead charge.

Wyoming crude oil is used to ignite the charge, and is delivered at the burners at a pressure varying from 20 to 35 lb. per square inch, the pressure being controlled by rate of travel and character of feed. In 1912, an 80 lb. pressure was used on gasoline fuel with a vacuum under the blanket of about 4 ounces. The vacuum used at the present time, with crude oil, varies from 7 to 8 oz. The main objection to the crude oil is that it requires a burner that gives too wide a zone of ignition, thereby keeping the charge under the flame for too long a time, resulting in the fusing of the surface of the charge and thus not permitting of a free passage of air through the blanket. The life of the fire-box is short when using this fuel, being burnt through in about three weeks. The roaster foreman claims that better work was accomplished with the narrow ignition zone of gasoline and the low vacuum.

The wind-boxes are cleaned weekly. Recent design favors a bottom of such shape as permits a screw-conveyor to remove the leakage of fine into a closed hopper, which should be emptied about twice per shift.

Cast-iron grates were found not to last under the East Helena conditions; they have been replaced by malleable iron. This failure in grates was due, I think, not so much to the class of material used as to the spraying of water on the sinter just before dumping, thus chilling the iron and re-crystallizing it. The sinter is now wetted in the cars instead of on the grates. All break-holes in the grates should be filled with waste-paper before charging to prevent excess leakage into the pit and wind-box.

The East Helena plant is equipped with six (only three in use for two blast-furnaces) 42 by 264-in. straight-line Dwight-Lloyd sinterers. The herring-bone type of grate has been replaced by straight-slotted grates, as these are easier barred out and permit of a cleaner discharge of sinter from the machines.

For three roasters the following working force is employed:

	Per shift
1 foreman (also handles H. & H. department)	$4.65
1 machine-man	$3.75
6 grate-punchers, each	$2.70
1 oiler	$3.15
2 laborers in pit, each	$2.50
Charge and sinter wheeler, as necessary, each	$2.70

Care of Machines. When one or more machines are driven in battery (as at East Helena) from a main shaft, they should be started consecutively and care should be taken to see that the grate-wheels, sprocket-wheels, and rails are well lubricated. Two men should be placed in the pit to bar the grates along in case they should stick at any point, and so avoid open spaces between grates. Dust and grit should be removed from movable parts at least twice per shift. Grates should be punched clean to allow free passage of air through the charge. As soon as the ignition-box is burned through it ought to be replaced in order to cut down the width of the ignition zone.

Statement of Performances. The foreman claims that even under the most favorable conditions the sulphur reduction on the Dwight Lloyd is rarely under 4% final, and in the 'double roast' often as high as 8%.

Year	Tonnage	Sulphur— Initial %	Sulphur— Final %	Remarks
1912	110	12	3½ to 5	Gasoline at 80 lb.
1913	110	11	5	
1915 (single)	131	11 or less	6	Crude oil at 20 lb., little CaO
1915 (double)	230	11 or less	6 to 7	Crude oil at 20 lb., much CaO

Character of Dwight-Lloyd Sinter. The management claims many advantages for the Dwight-Lloyd product over the H. & H., for example, its coke-like structure entails less fuel on the blast-furnace charge (2% less coke for the Dwight-Lloyd than for H. & H. sinter). Excess fuel means diminished furnace speed with a tendency to over-fire, causing poor reduction in the slag and matte. Hot tops mean hot gases for the bag-house, and the peculiar cellular structure of the Dwight-Lloyd sinter allows the reduction of the gases to be carried on over a maximum area of contact. To offset these advantages, the fact remains that even under the best operating conditions the Dwight-Lloyd product retains 4% and more of sulphur, and to reduce below this point requires a big sacrifice in tonnage. High sulphur on the blast-furnace charges at East Helena is objectionable on account of the high zinc-content of the feed.

Handling of Dwight-Lloyd Product. The sinter-cakes are jarred off the end of the machine into tram-cars (capacity about 1½ tons). These cars stand under hoods that carry off most of the gas and smoke coming from the roasted sinter. Any sinter sticking to the grates is barred loose by hand. The loaded push-cars are hand-trammed (2 men) for about 500 ft. to the railroad-track, where they are dumped into open 55 ton railroad-cars. During the course of loading these cars, the sinter is thoroughly wetted with a 2-inch hose. The loaded and moistened sinter is held for 24 hours, during which time it cools and partly disintegrates due to the slaking of the lime. The loads are then brought to the sampling-mill, where the sinter is re-crushed to ½-inch and re-loaded into railroad-cars.

From this point the 'double roasting' process passes to the Huntington & Heberlein or 'H. & H.' department.

Secondary-Roasting Pots

Description of Plant. The H. & H. pots are contained in a large corrugated iron building, open on three sides and ventilated throughout the entire length of the roof. Too much emphasis cannot be placed on the necessity for properly ventilating this department, as the men tending the pots are subjected to excessive amounts of fume and steam. At East Helena, the pots are situated at a considerable distance from the Dwight-Lloyd department, necessitating costly handling, in railroad-cars, of the 'single roast' before charging into the pots (see Conclusions). There are 12 cast-iron pots, the empty weight of each being 12,700 pounds. Six extra pots are kept in reserve in case of a break-down. These extras are also used in charging the operating pots. The roasted charge varies from 15,000 to 19,500 lb., depending upon the class of feed treated and also upon the height to which the charge is piled up in the pot.

Two electric-driven traveling cranes are employed. One operates in the pit, loading and changing the pots; the other carries, dumps, and assists in breaking the roasted sinter on the floor. The last is accomplished by dropping an iron weight on the larger pieces of sinter. After this preliminary crushing the sinter is conveyed, by means of a scraper, to a crusher breaking to 6-inch size. The crushed material is elevated in a skip and dumped into storage-bins, and from there taken direct to the blast-furnaces.

Priming Pots. The bottom of the empty pot is covered with several (3 or 4) inches of dead clinkers from the boiler-room. A good wheelbarrow-load, per pot, serves amply. Over this, with the blast slightly on, is charged two or so inches of small coal, ignited in a Godfrey fire-box. This coal is drawn, while incandescent, into a charge-car. The best plan is to draw one fire completely and to distribute its coal to several pots simultaneously, by aid of the crane. A level wheelbarrow-load is enough for each pot. The coals should be spread evenly over the layer of clinkers, and the blast turned on slightly to get a good heat.

Charging Pots. After the priming has been completed, the blast should be stopped almost entirely and the full charge of sinter dumped into the pot. The charge should be well heaped, as after blowing it shows a shrinkage of about one-third. The pot is now ready; the hood is put in place and the full blast is turned on. The charge is made up from the 'single roast' from the Dwight-Lloyd sinterers, rather rich in lime and carrying from 6 to 7% sulphur. Up to January 1, 1916, this product did not receive a second crushing before treatment in the H. & H. pots, breaking-down due to the slaking of the lime content being entirely relied upon to prepare the charge. With the present practice, crushing to ¼-inch, it is found that a more thorough roast can be obtained, owing to the even distribution of the blast throughout the charge.

Moisture. In preparing the sinter for the roast it should be saturated with water; the best way would be to wet it down in bins and allow it to drain. If there is an excess of water in the wetted sinter, so that it adheres, say, like soft concrete, the blow will be inferior. The burn will come to the top in large blow-holes and the agglomerated charge will keep the hole open. In this case the sides should be broken down and green sinter hoed into the opening until it is brought up to the level of the

charge in the pot. However, the main thing to avoid is having the charge too dry, in which case the roast goes on at too high a temperature, causing excessive volatilization losses, lowering the production of lead sulphate and endangering the life of the pot. When the charge packs tightly, not allowing a free passage of the blast, it should be barred through in several places. When the charge is too dry, wholly or in part, water should be added to reduce combustion (through a 1-inch pipe, sparingly).

Operation of Pots. After the blast has been on for about an hour the pots should receive attention; this is essential when the sinter is fed to the pots uncrushed and when the wetting-down conditions are as crude as at this plant, since the charge is apt to burn unevenly. The proper burn, when conditions are reasonable, first indicates itself by the pots sinking in the centre. In this case the material around the edges should be pushed in and the surface made level. If the burn is uneven, elsewhere than in the centre, green sinter should be hoed over that portion burning fastest. All blow-holes ought to be treated as described above. When a pot smokes so badly that it cannot be dressed, the blast should be turned almost off until the dressing is completed; if turned off entirely, the fire is apt to flare back and burn up the tuyere-bags.

During the early part of the roast much steam rises; this condenses against the doors and hood-walls, leaving a reddish liquid deposit that is probably rich in lead sulphate. Then the charge is worried with a hoe in the course of blowing, the little particles that are sintered on the surface becoming covered with a similar coating. The larger pieces show it to some extent, but not nearly so much as the fine. This is one of the arguments given in favor of re-crushing the Dwight-Lloyd product before treating in the pots, as it shows that the fine crushed material serves as a filter for the fume given off during the blow. Care should be taken not to allow the fine to agglomerate too quickly.

When the pots are burned 'dead' the sinter is dumped by inverting the pots, using the crane, over the receiving-floor, and the large pieces of sinter are broken down as described above. The dumpings are quenched immediately with water. I think that if the spraying were put off for several hours after dumping, further reduction of sulphur would be obtained at no additional cost. The wetting-down assists in breaking and cooling the roasted sinter, owing to the slaking and exothermic reaction of the lime, respectively.

Incidentally, the air-chamber at the bottom of the pot should be raked out when tilted and before re-setting in the pocket.

Time and Capacity. The actual time consumed in running this secondary roast varies from 5 to 7 hours, and the 12 pots sinter about 460 tons of Dwight-Lloyd 'singles' per day, or about 38 tons per pot. There is no reason why the pots should not be charged every 7 hours, except the crude equipment and congested dumping-floor at East Helena. The loss in efficiency here is about 12½%.

Sulphur Elimination. This second roast brings down the sulphur from 6 or 7% in the Dwight-Lloyd sinter to 2% in the final product (the management claims as low as 1% at times). Personally, I think that 2½ to 3% would be a fair average for the final sulphur.

Scrap lead that leaks through the grates into the wind-box should not be thrown into the next charge, but fed direct to the blast-furnace.

Blast-Pressure. The blast-pressure on the pots, at East Helena, is 16 oz. per square inch. The pit crew consists of

	Per shift
1 foreman (also in charge of Dwight-Lloyds)	$4.65
1 pit foreman	$3.30
3 pit laborers, each	$2.65
1 crane-man (on pots)	$3.40
3 laborers for outside work, each	$2.85
1 sweeper (for three shifts)	$2.50

Comparison of Single and Double Roasts. From the following table it will be seen that the double roast sinters 50% more charge in the same time, with an additional 3.1 to 4.1% sulphur elimination than does the single roast.

	Number of pots	Tons roasted	Tons per pot	Sulphur Initial %	Sulphur Final %
Single roast	12	300	25	10	5.1
Double roast	12	460	38.3	6	2 to 1

Conclusions

In a custom smelter, such as the one operating at East Helena, having an exceptionally high lead charge and where the zinc content runs near the maximum for good lead smelting, the 'double roast' process seems to be the only available and satisfactory method for the elimination of sulphur. Prior to the adoption of the process, at this plant, the matte-fall had reached a maximum of 22%, and rarely came below 18%. This condition has existed ever since the installation of the flotation system in the Coeur d'Alene region; this increased the zinc content in the product shipped to the smelter and was further aggravated by the high prices of the metals, causing the local shippers to mine ores high in zinc (zinc penalty varies from 5 to 11% according to the shipper and locality). The slag and matte losses were above what was permitted in good practice, and it was not until this new system of roasting was adopted that they returned to the normal. If the plant was in a position to select the ores to be treated, for example, rejecting such shipments as would tend to bring the zinc content of the blast-furnace charge above 4%, then I think the Dwight-Lloyd's would reduce the sulphur sufficiently (3½ to 4%) to hold the matte-fall within reasonable limits (10 to 12%). It should be borne in mind that this sulphur percentage would be further reduced, say to 2 or 2½, when the blast-furnace feed is diluted with non-roasting ores. If a further selection was allowed the smelting company, permitting them to secure definite amounts of auriferous or argentiferous pyritic ores or concentrates, the feed could be mixed into an ideal charge for the Dwight machines; the initial sulphur could be brought

up to from 11 to 16%. Of course, this would necessitate reducing the lead on the charge, but by operating one or two extra machines the lead output could be kept to the standard, and all the good resulting from the coke-like sinter produced from this machine could be taken advantage of, for example, less consumption of fuel on the blast-furnaces, better control of furnace heat, and an even distribution of iron flux in the charge. The lime would have to be cut down on account of its slaking properties, but this could be remedied partly by mixing it with oxidized or non-roasting ores.

From the above considerations it will be seen that many of the advantages of this system are counteracted by poor facilities for handling. The plant should be so designed that the charge from the mixing-bins can be conveyed, either by gravity or mechanically, direct to the Dwight-Lloyds. The sinter from these machines should have a gravity drop to storage-bins or coolers, and tapped from these into a crushing-department and then fall direct to the H. & H. feed-pots. The East Helena plant employs three men to do one man's work, and I consider this a low estimate.

Instead of wetting down the sinter, from both the Dwight-Lloyd and the H. & H. roaster, as soon as it leaves the machines, I think a further extraction of sulphur could be obtained, without additional cost, by allowing the roasted product to stand in the coolers, for 24 hours or longer, acted upon by a natural draft and protected by a hood to carry off the gas and fume.

The roasting costs, at East Helena, are as follows: the 'single roast' costs 50c. per ton of charge fed to the Dwight-Lloyd sinterers. The 'double roast' costs 30c. per ton on the Dwights, 10c. per ton for re-crushing, and 25c. per ton of feed on the H. & H. pots, making a total of 65c. per ton of charge roasted. With proper handling facilities no doubt this could be reduced at least 30%.

The method for preparing the Dwight sinter for the H. & H. pots has been revised. It is no longer run through the entire sampling-mill, but only through a gyratory crusher, which breaks about 75% of the product better than 1-inch size.

Since writing the above report, the management has created the position of assistant foreman to look after the H. & H. department. The general roaster foreman says this is hardly necessary as one man should have ample time to care for both branches of roasting.

Much of the Dwight-Lloyd difficulties could be overcome by installing an ignition system with a narrow flame zone, and also by designing some efficient form of mechanical grate-puncher.

The method for sampling and weighing the feed and products for the roasters are too inaccurate, at East Helena, affording the metallurgist but poor chance to check the work of the department.

GOLD yield of the Rand in January was 787,467 fine oz. from 2,505,232 tons of ore. To reduce this there were 9977 stamps and 328 tube-mills operated for 26.98 and 27.37 days respectively. Of the $6.16 average value of the ore the working profit was $1.88 per ton.

Flotation at Inspiration

In February of this year the full complement of 18 units in the new mill of the Inspiration was in operation. One day early in April there was hoisted from the mine 18,000 tons of ore. During the second half of 1915 the mill treated 778,851 tons of ore. Results were as follows:

	%
Copper content	1.702
Oxide copper in ore	0.226
Copper in tailing	0.373
Oxide copper in tailing	0.18
Table concentrate	13.12
Flotation concentrate	37.63
Average assay of concentrate	32.67
Recovery on sulphide copper ore	88.56
Recovery on all copper ore	79.95

To produce 1 ton of concentrate 24.6 tons of ore was treated. The cost of coarse crushing was 0.113c. per pound; hauling ore to mill, 0.079c.; concentration and royalty, 1.889c.; hauling concentrate to smelter, 0.006c.; smelting, freight, refining, marketing, etc., 3.455c., a total of 5.492c. for treatment.

The following notes are from the report of the general manager, C. E. Mills.

"In the report of a year ago it was stated that the test-mill operations to that date showed a saving of copper present in the ore as a sulphide of 86.7%, and that we might count on doing as well in the new mill. Operation of the new mill for the last six months of 1915 showed a saving of 88.56% of copper present in the ore as a sulphide. During much of this period the flotation units were overloaded, because the grinding units came into service faster than the flotation sections were completed, and the loads on those in service were temporarily doubled-up in consequence. For February 1916, the saving of sulphide copper was 91.1%. The saving of 88.56% of sulphide copper in the new mill for the last six months of 1915 was on an ore that averaged 1.702% total copper, of which 0.226% was in oxide combination. We apparently saved 24% of this oxide copper, and the resulting average saving of total copper contents of the ore milled in the new mill was 79.95%.

"Since August 1914, in the test-mill, and later in the new mill, we have continued to use coal-tar as the chief component in the frothing-mixture. It has seemed the most efficient agent, also the cheapest. During this time we have not experienced the violent fluctuations in recoveries we feared, and which we previously had with some other frothing-agents.

"The test-mill worked from January 3, 1914, to June 30, 1915, and treated 257,272 tons of ore. From the latter date until February 8, 1916, it operated as a temporary unit in the general concentrating process, when it was closed down, having treated a total of 373,705 tons. Contrary to usual experience this test-mill paid the cost of its construction, its operating expense, the present average mining cost on ores treated and something besides, and has been written-off the books."

Operating costs at Inspiration for mining and milling will probably be from $1 to $1.15 per ton of ore.

Heard in the Bunk-House—I and II

By W. H. Storms

I

"DON'T you know there's a lot of luck in mining?" remarked the boss timber-man of the King Solomon mine, one night in the bunk-house.

"That's right," exclaimed 'Swede' Murphy. "Luck's the word. I have knowed a lot of fellows who had plenty of savey, but they never could seem to hit it. Then, there's others that don't know nothin' that go out and strike it the first day."

"That's so," remarked the miner from Arizona. "It makes me think of the old Silver King, over in Pinal county."

"And how was that?" inquired Murphy.

"There was four men at Florence," explained the Arizona man. "There was Regan, Copeland, Mason, and Long. They had a pretty good copper claim 40 miles back of Florence in the mountains. They called it the Globe mine. Pinal county had just been formed and it was the day of the first county election, and Florence was the county seat. All hands was celebrating pretty free. These four men were making arrangements to go down with a pack-train over to their copper prospect, and bring down some ore to have it worked in the new smelter that had just been finished at Tucson. They had a parting jolt at one of the bars of the town and invited a soldier standing near to join them. They had more drinks, and this soldier got quite friendly. He said he knew where they could find a rich mine if they cared to look for it. They didn't take much stock in the soldier, but he was a chummy cuss, so they let him tell his yarn. He said he had a partner named Sullivan who had died, but that before he died he had told him about this rich place. He himself knew nothing of mining, so had never looked for it, but if they wanted it they could have it. 'Now,' says this soldier, 'my pard tells me like this. You will go up the Stoneman grade and you will pass some tanks; then you'll pass old Pickett Post; about five miles beyond you will come to a little basin like, all surrounded by hills, and near the head of this valley you will see a lot of big boulders that have rolled down from the cliffs. They lie by the side of the road: just a bit beyond you will see a little brown hill all alone by itself. In that hill, if my dead pal was right, you will find the richest mine in the world, and,' continued the soldier, 'gents, you are welcome to it.'

"The party started next morning for their Globe mine. On their way they saw the several things described by the soldier—the tanks on the Stoneman grade; Pickett Post; the valley surrounded by high rough hills and the boulders, and, just beyond, was the little brown hill, just as described by the soldier. 'There,' said Regan, pointing to the knoll, 'is our soldier's little brown hill and the richest mine in the world.' Everybody laughed, and the party went on without even stopping to take a look at it. They reached the copper mine, loaded the pack-animals with rich ore and started back.

"When they again came in sight of the little valley, Regan, who was the leader of the outfit, gazed at the brown knoll, meditated a little, and, turning to Copeland, who had more experience than any of the others, said: 'Copeland, I will lead the horse; you go over and just take a look at that little hill, and we will camp in the same place we did on the way up.' Copeland went alone over to the hill, climbed to the top of it and at once saw an outcrop of high-grade silver ore—metal till you couldn't rest. Some of it was worth $20,000 a ton. Selecting a few pieces Copeland went down to camp. Next morning the whole party went and staked all the ground they wanted. The rock was so rich they ran out a bar of silver in their portable forge, so they left the copper ore and took silver ore instead. They took 1500 pounds down to Tucson and sold it for $800 cash. By April 15 they had the shaft started and went on down with it. The ore was rich to 700 ft., but there it gave out. Other shafts were sunk, some of them over 1000 ft., but none of them got much. The Silver King never levied an assessment. It paid its way from the surface to the bottom of the shoot, and produced several millions of dollars worth of silver. It was one of the richest mines ever found in Arizona, or anywhere else."

"An' ye call that luck?" remarked Murphy, at the conclusion of the miner's story.

"Sure, I do," replied the man from Arizona.

"So do I," sententiously added Murphy, "pure, bull-headed luck."

"Suppose they had not taken a look at it, even," ventured one of the miners present.

"That," responded the Arizona miner, "would have been damned bad luck for all of them."

II

"Do you believe in ghosts?" asked the timber-man of the Arizona miner. "Some people do, you know."

"No, I don't," was the reply. "But I have known some people who do—at any rate they go to fortune-tellers and spiritualists, and that kind of people to get information and advice on mines. I don't go anything on them myself though."

"I knew an outfit once, up in the Black Hills," said 'Swede' Murphy, "an' it was a dandy. They was strong for ghosts. They called it the Golden Gravel Mining Company, or some such name. They was none

of them miners, but they had quite a bit of money, an' instead of hirin' somebody that knew somethin' about minin,' these fellows paid a fine salary to a Madame somebody, who was a spiritualist, to steer 'em in the minin' game. Her first break is to advise 'em to buy a big bank of gravel on Castle creek because this gravel was rich in gold, which was news to the people who lived in that part of the country, but the Madame had a straight tip on it from the ghost of an old Sioux Indian chief. She went into a trance, an' this chief tells her the gravel is rich in gold, an' as the Indians had lived in the Black Hills for years before the white men came they ought to know better than anybody. The gravel lay up 50 to 60 ft. higher than the creek, an' the only way it could be worked was by hydraulic. To do this the company had to dig a ditch five miles long. This was done, but while they was diggin' it looked as if they might want more water than one ditch could bring in, so they dug a second one on the opposite side of the canyon. I expect you can see them old ditches yet, about 5 or 6 miles above the place where the South Fork comes into the main stream. When the ditches had been dug, pipelines laid, sluices built, and everything ready, they turned in the water and run the hydraulic night an' day for about a week and then they shut off the water to make a kind of clean-up to see how the thing was going. They found plenty of nice smooth iron-rock and other heavy stuff, but only about four-bits worth of gold. This gold was so fine you could almost blow it away. It took about a million colors to make a cent. The company shut down and ran for Madame. But she did another fit, and when she came to again she said the old Indian had not been quite clear in what he said the first time; that it was not in the gravel, but in the veins of upper Castle creek that big money lay in copper and silver. This satisfied these guys, and they went to work again as cheerful as chipmunks, diggin' open-cuts, sinkin' little shafts, and runnin' tunnels some of them in over 100 ft. This work was done wherever they could find a stain of copper, which was in quite a good many places. The rocks there is slate, an' quartzite, and this bright shinin' silver-lookin' rock the geologists call phyllite—a good name, I expect, though I don't know why. For all their work they only got a few stringers of poor copper ore an' no silver at all—didn't amount to nothin,' so they give up an' went on the run for Madame once more.

"This time she near died in one of her spells, but she got back alive after a while, an' then she told them about a mine of very rich gold ore about two miles from Deadwood. The old lady had got this tip straight from the ghost of old Father DeSmet, himself, who knew the Hills better than anybody. She said the old Indian chief had been givin' her the double-cross, and she would have nothin' more to do with the likes o' him. The ground pointed out by the Madame was bought—I'm thinkin' she must have got a pretty good commission on all of these deals. So they went at it once more. The Madame wasn't only a minin' expert, she put up a bluff at bein' a chemist too, as well as an assayer, an' she got some fine gold buttons from the bum rock they dug out of the hill near-by, though nobody else could get anything more than a few cents a ton out of the stuff. The rock couldn't be worked by any ordinary mill process, the Madame claimed, but this didn't stump her any. She just had another fit when some ghost friend of hers told her how to build a mill that would do the business all right, and the suckers fell for it again. I seed this mill once, when I was a young fellow. I ain't never seen another like it. It sure was a peach. It had a steam-stamp that worked in a round mortar with a screen all round like a drum. Below this stamp was six iron basins 5 ft. across and 8 in. deep. They was painted bright red and reminded me of six red-hot saucers. Besides these there was roasters and vats, and pulverizers, and I don't remember all else. When the mill was finished it had cost over $25,000. Remember it was 250 miles or more to the nearest railroad them days and every bloomin' thing had to be brought into the country by bull-trains or mules. When she was finished they started up and treated 4 or 5 tons of the rock, got nothin' an' quit.

"This discouraged the company. They had spent over a hundred thousand. As they couldn't pay Madame her big salary any more, bein' broke, she quit 'em cold—wouldn't have nothin' more to do with 'em. The old mill stood there for years, at a place called Gayville, about two miles up the gulch from Deadwood, but I expect it is all gone now—for old iron, I suppose."

Operations of the United States Steel Corporation and its subsidiaries in the past two years resulted as follows:

Materials produced	1915 Tons	1914 Tons
Iron ore mined	23,669,676	17,034,981
Coal mined	26,628,482	21,162,293
Coke made	14,500,818	11,173,914
Limestone quarried	5,795,925	4,676,479
Pig-iron, ferro, and spiegel	13,641,508	10,052,457
Steel ingots (bessemer and open-hearth)	16,376,492	11,826,476
Rolled and other finished products	11,762,639	9,014,512
Universal portland cement, barrels	7,648,658	9,116,000

The total value of business was $486,352,054, compared with $380,228,143 in 1914, an increase of 27.9%. Export business increased 122.4%, and domestic 15.9 per cent.

El Paso, Texas, is a well known mining and smelting centre, particularly for the American-owned mines in northern Mexico. An early Spanish explorer, it is stated, forded the Rio Grande in 1598 and named the place El Paso del Norte—the pass of the North. But not until the period of the Mexican war seventy years ago did El Paso change from a ranch to a border town. An old Spanish mission church was built at Juarez, just across the Rio Grande, about 1650.

Coal production of Michigan in 1915 was 1,156,138 tons, averaging $2.05 per ton, a small decrease.

CONCENTRATES

Readers of the MINING and Scientific PRESS are invited to ask questions and give information dealing with technical and other matters pertaining to the practice of mining, milling, and smelting.

Cost of the survey represented on maps sold for 10c. by the U. S. Geological Survey may be as much as $5000.

Cost of hydro-electric power at the Alaska Gastineau mine in 1915 was 0.268c. per kw.-hour, or 4.8c. per ton mined and milled.

Miners applying for work at the Copper Queen, Arizona, are physically examined. This has reduced accidents and sickness, and increased efficiency.

Supplies costing less per pound may cost more per year, because it is necessary to use so much more of an inferior material to accomplish the same result.

Fatal accidents of the Copper Queen company in 1915 were only 1.05 per 1000 men employed, compared to 3.16 in 1914. This decided reduction was brought about by the work of the company's safety department.

Heating pulp for flotation has the effect of minimizing the force of adhesion that tends to surround the mineral particles with water; that is, to wet them and thereby detach the air-bubbles which are instrumental in floating them to the surface.

Searles Lake, in south-eastern California, contains the most valuable potash-bearing brine known in the United States. The exposed surface area is 11 or 12 sq. miles, and an average depth of 70 ft. The brine contains 2.1% potassium, equal to 4% potassium chloride.

Raising oil from wells by air-lifts may be more satisfactory than by using pumps. An air-lift is suited to raising liquid containing sand, mud, or slime. At Bakersfield, California, an air-lift in one oil-well raised oil 1200 ft. with compressed air at 182 lb., submergence 30%.

Auxiliary pumps for emergencies when the regular equipment reaches its limit, at the Old Dominion mine, Globe, Arizona, were replaced by air-lifts, on account of the "much greater pumping capacity, freedom from shut-downs and more or less automatic operation" of the latter.

Graphite grease is used for the lubrication of heavy machinery. It is said to adhere with exceptional tenacity, provided it is applied when the surface is dry. It is recommended for pump-plungers, steam-shovel chains, gears, hoisting, and transmission cables. It washes off with difficulty, so that it resists mine-water, sea-water, or drippings.

Scheelite concentrate containing bismuth is not keenly desired by ore-buyers. Bismuth gives as much trouble as tin and molybdenum. The presence of gold and silver would not enhance the value of tungsten ore to any great extent, as it is difficult to extract the precious metals. Cyanidation of the concentrate before shipment might be suitable.

Metallic magnesium, when added to aluminum castings in the proportion of 2% or less, has the excellent effect of making cleaner castings, doubling the tensile strength, and quadrupling the resistance to shock or jar. The cost of machining is reduced more than 50% and a more clean-cut machined surface results. Magnesium metal is recommended as a substitute for aluminum and copper in the making of alloys. It makes excellent castings, is a third lighter than aluminum, can be made two to four times as strong, is as resistant to corrosion when pure, and has an equal electrical conductivity.

Heating a large building by electricity in a northern climate is exemplified by a new large concrete high-school at Burley, Idaho. Using two of the three stories of the building, the total cubical content of which is 780,000 cu. ft., the heating bill for the year is $1800 with electricity at $1 per kilowatt per month, based on the maximum service during the month. The current is reduced at the building from 2200 to 220 or 440 volts depending on the heat desired. The cost per year seems high, but the labor required is almost negligible, as are space, stack, and coal-smoke. The current is supplied by the Minidoka plant of the U. S. Reclamation Service.

Wire rope wears from four principal causes, namely, abrasion, undue bending, over-strain, and corrosion. Abrasion is caused frequently by faulty grooves on sheaves or from dragging of the rope on the ground. To prevent corrosion, wire rope should be lubricated and kept as free from water as possible. The core of a wire rope is usually hemp saturated with a lubricant; it provides little additional strength, but acts as a cushion to preserve the shape of the rope and helps to lubricate the wires. Standard wire rope, such as for hoisting, is made of six wire strands over a hemp core, each strand containing 19 wires. Ropes with 12 or 7 wires per strand are stiffer, being more adapted for standing rope, guys, and rigging.

Belts are expensive when improperly installed or cared-for, whether they be leather, camel-hair, canvas, cotton, or other material. The endless, jointless belt gives the best service, as joints are always weaker than the main part of the belt. To make an endless belt the joint should be similar to that made by the manufacturers—cemented, or cemented and riveted. If a laced joint is decided on, taking the efficiency of the endless belt at 100, wire-lacing is 95, and rawhide-lacing 80, according to W. F. Schaphorst in *The Iron Age*. Belts should be pliable in all ways, especially longitudinally, so as to wrap close about pulleys. Belts must not be allowed to slip; to prevent this they should be kept at the proper tension or dressed occasionally.

REVIEW OF MINING

As seen at the world's great mining centres by our own correspondents.

JOHANNESBURG, TRANSVAAL

Companies and Their Staffs.—West Rand Development.

The Rand goes on its even way. At the mines and in Johannesburg generally the immediate effects of the War are less felt than in any part of the Empire. Most of the financial groups have been most generous in giving their employees leave to join the forces in Flanders or East Africa. Half-pay for married men and quarter-pay for single is the general rule. I know of cases where men have given their services for a week or two on a mine, and then been allowed to join the forces on half or quarter pay. The groups known before the War as of German origin and control have been particularly liberal. Of course, on any one mine the management can only be allowed a limited number of men who are to receive half or quarter pay. This means that even with the liberal arrangements made, some men are bound to be disappointed, and feel they have a grievance. There is one group, however, where perfect harmony prevails, and no complaints are heard of any kind. That is because, from highest to lowest, all are treated absolutely impartially. Nothing in any shape is being given or promised to anybody, hence there is no discontent or grumbling. It has not, however, prevented a lot of men going to try and do their bit. More power to their elbow!

Well, about the mines, the Far East Rand is the fashion, and the excellent results of the Springs mines development has largely helped to boom this district. Things are going strong, and look like going stronger yet. It is quite certain, of course, that judging by the past, the thing will be overdone. A new formula is being preached, the 50% one. Only have an area big enough, and you are rich beyond the dreams of avarice. Still, prospects out here are brighter than looked at all likely at one time, and many more mines may be opened up to give work to the poor man. And may the plucky firm of Barnato Bros. and the Mines Selection Company have their legitimate reward! It is a pity, however, that the Union government does not follow the excellent example of the West Australian government and make all mine-plans, including assay-plans, free to the public. At present, one has to rely on a carefully edited monthly or quarterly report. Certainly the reports published by most of the groups give far more details than they used to. Still there is a lot to be done before we are anywhere near the West Australian standard. The idea that the shareholder is a young child, and should only be told what his parents would like him to believe, is by no means dead yet. Outside the developments on the Far East Rand, a most important fact, and one that may be news to some of you is that on the Western Rand extensive exploratory work and a lot of mining is being done on two, at least, of the lower-grade but wide reefs lying to the south of the Main Reef series. The Kimberley series is being mined on the West Rand Consolidated, and the Randfontein Estates is extensively mining on what is probably the Bird Reef series. Of course, both of these mines are continuing work on the Main Reef series proper. If these southern bankets continue profitable, there is no reason why they should not do so in the other mines. Little or no intelligent exploratory work has so far been done on these 'reefs,' except on the mines I have mentioned. Now is the time for you American financiers, not perhaps to buy shares, but to come over and see things for yourselves.

JOPLIN, MISSOURI

United States Zinc Smelting Corporation's Activities.—From Poor Prospect to Rich Mine.—Calamine and Lead Pocket Mining.

The United States Zinc Smelting Corporation, which has acquired the holdings of William Kenefick in the Joplin district, reports three drill strikes, two exceptionally good, on a 26-acre lease of the Muskingum Mining Co.'s land, one mile west of Joplin. Construction of a 350-ton concentrating plant entirely new, is to be started early in May. Properties operated by the U. S. Corporation are the Media Mining Co. and the Electrical Zinc & Lead Mining Co., north of Webb City; the Coyote Mining Co., and the Airedale Mining Co., west of Joplin; and the Milan Mining Co., at Prosperity. To this list will be added the new mine on the Muskingum land. This lease adjoins the Coyote mine on the north and practically the same run of ore is to be worked. Drilling on the Muskingum lease showed sheet-ore beginning at a depth of 181 ft., continuing to 195 ft. Assays of the drill clippings gave an average of 3½% blende and lead, from which a mill recovery of almost 3% can be expected. This is about the same saving being made by the company's Coyote and Airedale mines. Formation of the Corporation was perfected at Albany, N. Y., during the latter part of April; 600,000 shares, of no par value, are issued. Included with the Kenefick interests is the Pearlman company, operators of the Clarksburg, West Virginia, Zinc Smelting Co. The officers of the new company are William Kenefick, president; R. A. Cowles, vice-president; and Arthur Day, treasurer. The company claims to operate mines from which 25% of the high-grade zinc-blende of the Joplin district is produced.

Stories of get-rich-quick mining propositions in the Joplin district are frequently grossly exaggerated, especially during the past year or two of record-breaking ore prices; but an occasional instance sometimes arises which is so striking that it proves interesting. The development of a profitable mine, as a rule, covers a period of several years. The opening of the Emperor mine, on a 40-acre lease of the American Zinc, Lead & Smelting Co.'s land, two miles west of Joplin, occupied a period of only a few months, and is now rated as one of the heaviest temporary producers of the west Joplin field. Charles T. Rhodes and W. T. Crane found it a difficult matter to raise $150 when they began prospecting on their lease on July 4, 1915. Their only equipment was an overworked hoist, housed in a fragile derrick. At the end of the first two weeks' work they found it necessary to divide their interests with others in order to provide operating expenses. Five partners were eventually taken in; but even with this co-operation of funds, the regular Saturday night assessments became so irksome that it looked much as though the Emperor lease was to be abandoned through sheer inability to raise enough money to continue the work. At a crucial moment, when prospecting was about to stop, a heading broke into a pocket of rich blende and lead. It became necessary to sink a new shaft because of the bar character of the ground, but with good prospects ahead, the partners borrowed enough money to carry on their work and the new shaft was put down a depth of 75 ft., and started driving. Four drifts were put into the orebody, and the 'dirt' was treated at a custom mill. The first few lots showed the ore to carry more than 20%

blende and some lead, and the cleaned blende concentrate contained over 59% metallic zinc. In a few weeks the partners had the cash in hand to construct a new 150-ton mill, which is now working steadily, producing as high as 14 tons of concentrate per day, and seldom less than 10 tons. While the ore is so rich that it is doubtful if the formation is extensive, still the drifts continue to show the same run of ore, and recent prospecting opened a good stope under the old workings. The five partners are now clearing from $300 to $1000 per week each.

South of Carthage, on the land of Henry Weymann of Joplin, several families are operating on shallow calamine deposits. The word 'families' is used correctly, as a visit to the land proves. Children, men, and women are at work in gouges that are not more than 6 ft. deep. Not only is calamine taken out, but an occasional pocket of free lead is found which places the owner of that particular mine in the 'bonanza' class until his riches have been exhausted. As a rule the ore-pockets are not extensive.

HANOVER, NEW MEXICO

Operations of the Empire Zinc Co.

The Empire Zinc Co. of Denver, Colorado, has been operating its zinc mine here for several years, shipping zinc carbonate direct to the smelter. Now, however, as the mine is being developed below the 150-ft. level, and the orebody is found mainly to consist of zinc sulphide, associated with pyrite, chalcopyrite, and other minerals, the company decided to construct a concentrating plant to make a product suitable for shipment to smelters. Building operations were commenced on November 1, 1915, and it is expected that the mill will be completed and in operation by June 15 of this year.

NEW MILL, ETC., OF THE EMPIRE ZINC CO.

The scarcity of water in this district necessitates dry crushing throughout. The ore is first broken by a Blake type crusher. This product is conveyed to four rolls (manufactured by the Power & Mining Machinery Co.), then to incline screens, the final material obtained by Rowan-Wetherill magnetic type electro-static separators, eight of which are installed in the mill. The total capacity will be 150 tons per day.

Power is obtained from a 250-hp. Snow-Diesel type two-cylinder four-cycle engine, driving one 75-kw. a.c. and one 75-kw. d.c. generator, which supplies all the power required to operate the mill.

A number of comfortable dwellings have recently been built for the employees of the company; in all about 30 structures, including the mill and power-house. The latter two buildings, by the way, have been painted a brilliant vermilion, adding a touch of color to the otherwise dun-colored scenery, making a distinctive land-mark which can be seen for miles in almost every direction.

K. A. Strand is superintendent with C. J. Brown assistant, and C. A. Schmidt in general charge.

TORONTO, ONTARIO

Report on Kowkash.—Flotation and General Progress in the Cobalt District.

The Kowkash gold area is likely to attract many prospectors this season, especially the western section around Tashota, 22 miles west of Kowkash station. The Ontario Bureau of Mines has issued a report by P. E. Hopkins, who made an examination of the area last fall, descriptive of the geology of the locality and the principal discoveries so far made. The formation of the area is pre-Cambrian, the rocks being dominantly of Keewatin age, with some Temiskaming sediments and later intrusions of feldspar-porphyry, granite, and diabase. This formation, similar in character to that of Porcupine, extends over a territory of 600 square miles. While gold is widely distributed, enough work has not been done to prove its occurrence in commercial quantities. Mr. Hopkins regards the district as worthy of thorough prospecting, not only for gold but for iron ore and pyrite. At the King Dodds claim, the original discovery, a 14-ft. pit was sunk, but the free gold disappeared a few feet down, and samples at the bottom of the shaft gave low assays only. What appears to be the most promising discovery was made on the Devanney claim, near Tashota, where a vein averaging 12 in. or more has been traced for 600 ft. It carries fine gold and a telluride in considerable amount, and high assays have been obtained. In all, over 1000 claims have been staked, mainly around Tashota, near the Dodds discovery, and in the vicinity of the railway between Kowkash and Tashota stations. The four Devanney claims have been purchased by Boston interests, and supplies are now being taken in. Work will be started in a few days.

Activity in silver mining has been considerably stimulated lately by the increased price of the metal. Flotation is making steady progress at Cobalt, and it is considered probable that old dumps of tailing can be profitably re-treated by this process, in addition to making available a large amount of low-grade ore now left underground. The Callow system is the one adopted. The Nipissing has treated several hundred tons of ore in its experimental plant. The installation of the 150-ton plant at the McKinley-Darragh has been retarded by delays in the delivery of machinery, but it is expected to be in operation in May. The Buffalo plant will have a capacity of 600 tons per day, and its construction is well advanced. The Buffalo is now making a recovery of quicksilver by a new process and making shipments to the head office in Buffalo.

The new cyanide mill at the Coniagas is at full capacity, 180 tons per day. The mine has enough ore to keep the plant supplied for two years.——The Trethewey company has cut a new vein in the old Rochester property. It is 3 to 5 in. wide, and assays from 500 to 2000 oz. silver per ton.——The annual report of the Beaver Consolidated for the year ended February 28 shows gross earnings of $351,124, and profits of $128,929. Production was curtailed during the year owing to the low price of silver. The recovery was 746,310 oz. from the treatment of 30,093 tons of ore. There is 34,332 tons of broken ore ready for milling.——The Seneca-Superior has closed down, the vein being worked out.

There is much activity shown in the outlying parts of the Cobalt field.——In Gowganda the Reeves Dobie is mining high-grade ore, and rich ore is reported at the Bishop mine. ——Several Elk Lake properties are being re-opened.——In South Lorrain the Comfort company is erecting a mill.

THE MINING SUMMARY

The news of the week as told by our special correspondents and compiled from the local press.

ALASKA

Bethel

(Special Correspondence.) Miners are busy hauling provisions and lumber to Canyon and Windy creeks. On Bear creek several miles of placer ground has been taken up under option. It is probable that the gold output of the Kuskokwim region will be greater this season than in 1915, which was the best since 1907. The gasoline schooner *Abler* was lost some time ago with supplies for Bethel. The power schooner *Bender Brothers* was frozen-in the Kuskokwim river just below Bethel. It is one of the pioneer vessels plying to this place with supplies for miners, the Government, traders, and missions. Its capacity is 250 tons. During this spring the *Ruby* of 450 tons, and *Hugh Hogen* of 1000 tons' capacity will run from Seattle to this place.

Bethel, February 10.

All construction work on the Government railway from Anchorage north has been stopped on account of labor troubles. The men demand 55c. per hour, in place of 35c. at present.

Later news states that the trouble has been settled.

Cordova

(Special Correspondence.)—Twenty-two copper claims on Hidden creek, 7 miles north-west of Kennecott, have been purchased by the G. F. Rowe company of Seattle from the Tjosevig brothers. A tramway is to be constructed across the glacier.

McCarthy, April 14.

Juneau

At the '300' mill of the Alaska Treadwell, the 400-hp. motor that has been working on the 'A' side for over 6 years has been transferred to the '700' mill of 120 stamps, a 500-hp. machine replacing it in the 300-stamp mill.

March returns of the three companies operating on Douglas island were as follows:

	Mexican	Treadwell	United
Stamps working	120	540	300
Ore crushed, tons	18,025	80,871	46,895
Gold production	$23,522	$134,022	$78,491
Operating expenses	27,780	103,593	73,706
Construction	5,652	10,400	10,530
Profit	.....	18,689	.....
Loss	10,145	.....	6,530

ARIZONA

Cochise County

Optimistic reports are heard from Johnson, a producer of gold, silver, copper, and tungsten ores. The population is over 1500, against 200 a year ago. The Arizona, Michigan, and Republic are the largest producers, making regular shipments to smelters. The Cobriza company employs 100 men, and mines 200 tons of copper pyrite daily. Several good properties are in the development stage.

Gila County

At the Inspiration mill some additions are to be made to increase the recovery of copper, foundations and steel work being prepared for this. Oliver filters will dry the flotation concentrate. Two-stage centrifugal pumps made by the Byron Jackson company of San Francisco have been installed to return the overflow water from the tailing pond to the mill. These machines have a capacity of 3000 gal. per minute.

Mohave County

Flotation plants each of 50-ton capacity are to be erected at the Leviathan copper and American molybdenum mines in the Cedar Valley district.

The Schuylkill mine at Chloride, which has an extension of the Tennessee veins, has started dewatering operations. This company shipped high-grade silver-lead ore to the Benson smelter in the early 80's, and large bodies of commercial ore were exposed on the 500-ft. level.

At 185 ft. in the Big Jim at Oatman the lode is 40 ft. wide, worth about $12 per ton. Near the foot-wall the ore was of better grade.

Copper claims 40 miles north of Chloride have been sampled by the Copper Queen Consolidated company.

Pima County

Much work is under way at the New Cornelia company's property at Ajo. Good progress is being made at the various shops and plant excavation. The company is also beautifying the town by planting trees in the plaza.

The A. S. & R. Co. has blown-in its furnaces at the Sasco smelter, to treat ore from the Imperial Copper Co. Outside mines will also supply ore, it being hauled over the Arizona Southern line.

Santa Cruz County

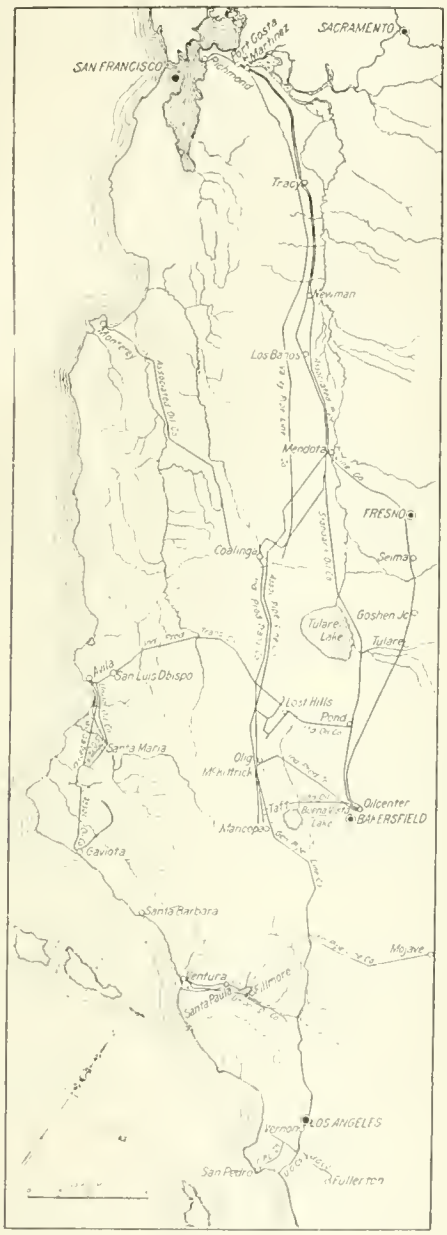
The Three R copper mine in the Patagonia district has been sold by R. R. Richardson to the Harrison interests of Mexico for $500,000, through the work of C. C. Sanders. A mill is to be erected to treat the low-grade ore. Under option the mine was profitably worked by N. L. Amster of Boston.

CALIFORNIA

The total oil production of California in 1915 has just been determined from the sworn statements made to the State Mineralogist by all of the 363 producers; it amounted to 88,240,620 bbl. This is doubtless the most accurate figure that has ever been obtained, and it is of interest to note that it is in close agreement with the figures given to the public at a much earlier date by two private concerns, namely, the Standard Oil Co. and the Independent Oil Producers Agency. Private parties publishing such information perform a distinct public service, the value of which should be more generally recognized, and encouragement given to enlarge its usefulness by touching on the quality of oil produced. Of the total amount of oil, 33%, or 29,587,163 bbl., was produced by the five large refining and marketing companies, and 16%, or 13,704,982 bbl. by the several large concerns, such as the railroad companies, who use the oil in their own service. The remaining 51%, or 44,948,475 bbl. is credited to the smaller producers who usually sell the crude oil at the well. The natural gas which was marketed has also been accounted for, giving a total of 11,962,000,000 cu. ft., over 90% of which was from Kern county. On the enlargement of its engineering force, in the near future, the State Mining Bureau intends to conduct a more detailed investigation of natural gas production with the idea of being able to point out means of more economical use of this splendid natural resource which is too frequently wasted.

The present extent of proved oil land in California has just been determined by the State Mining Bureau in the most accurate and detailed study ever given to the subject. The total

is 126 square miles, or 80,702 acres, of which 55,842 acres is in Kern county. Fresno county is second on the list with 12,218 acres, and Santa Barbara county third with 6030 acres. The other counties in their regular rank are Orange, 3305; Los Angeles, 2326; Ventura, 749; San Luis Obispo, 202; and Santa Clara, 30 acres. It is worthy of note that the total area of proved oil land is most insignificant in comparison with the



MAP SHOWING OIL PIPE-LINES IN CALIFORNIA.

area of the entire State, being less than 1 1000 part; yet the oil business is one of the State's most important industries. Estimates of the total amount of oil which can be recovered from the land are little better than pure guesses, but it seems most probable that the average acre will ultimately yield much less than 50,000 barrels.

It is said that the Shell Oil Co. will lay another pipe from Coalinga to Martinez, a distance of 180 miles. In the April number of *Western Engineering* the oil pipe-line systems of California are described by C. P. Bowie. Seven companies transport oil by pipe, having a total length of 2000 miles, with an estimated daily capacity of 370,000 bbl. The accompanying map shows the lines.

Final returns on the following minerals have been received by the State Mining Bureau for 1915:

Mineral	Tons	Value
Barytes	410	$620
Bituminous rock	17,789	61,468
Borax	67,004	1,663,520
Cement, barrels	4,846,313	5,972,988
Chrome	6,337	49,842
Dolomite	3,492	11,354
Feldspar	1,800	9,000
Iron ore	646	2,584
Lithia mica	91	1,365
Mineral paint	311	1,756

Under barytes is included a certain tonnage of witherite, the carbonate of barium. This is the first commercial deposit of witherite in the United States of which the Bureau has any record. The production of chrome is the largest in tonnage, though not in value, of any year since 1881. Dolomite is a new item in the commercial mineral list of California, at least this is the first year that it has been segregated as such. It was formerly included under limestone. The major portion of it was used for a basic lining in steel furnaces. Some nickel ore was taken out at the Friday copper mine in San Diego county; but as yet the owners have been unable to get any smelter to treat it for them. A discovery of tin ore has been noted from San Diego county, but no production has resulted yet. Molybdenite was mined in one or two localities in the latter part of 1915, but not marketed.

Alameda County

Near Tesla, south-east of Livermore, the Manganese Co. of California, in charge of E. A. Wiltsee, is dispatching 5 cars of ore each week to the East.

Calaveras County

Another dredge, No. 3, is to be constructed for the American Gold Dredging Co. (late Oro company) near Comanche on the Mokelumne river. Some of the machinery from its Victor dredge at Oroville will be used.

Eldorado County

After being idle since 1864 the Bunker Hill copper mine near Penobscot is being re-opened in charge of D. L. Shepherd.

Nevada County

The well-known, equipped, and developed Union Hill mine at Grass Valley, producing gold and tungsten, has been acquired by San Francisco people headed by F. W. McNear and E. L. Oliver. Errol McBoyle is general manager.

Plumas County

Eastern capital has purchased the White Lily gold mine near Seneca, and proposes to erect a large stamp-mill and cyanide-plant.

San Bernardino County

Three veins, 6, 8, and 12 ft. wide, containing high value in gold, have been opened by the Lietzow Consolidated, operating at Crucero, on the way to Barstow and Goldstone, the new district. The shoots are in limestone formation, near the porphyry contact. A complete equipment is to be bought. At the Desert Queen mine, 7 miles away, high-grade copper ore is being extracted.

The Owl Head manganese mine near Silver Lake is producing 970 tons of ore per month. Two more Holt 75-hp. caterpillar tractors have been acquired. Thirty-five men are employed. A railroad is being surveyed. The Mollett Development Co. of Massillon, Ohio, is owner. R. L. Mann is consulting engineer.

Shasta County

At the Friday-Lowden property of the Mammoth company the adit is in 1400 ft., with a daily advance of 15 ft. The final length is to be 4000 ft. The company has enlarged its social hall for employees at the Mammoth mine.

On April 29 fire at Harrison Gulch destroyed most of the town and mining property worth $100,000. The Victor company's Midas mine equipment suffered considerably. The cyanide-plant is again in operation.

Tuolumne County

(Special Correspondence.)—The Tarantula mine, near Shawmut has been taken over by Henry T. Gage, who, it is said, will operate the property connection with the claim on the Jones ranch which he has held for some time.——The Tansy mine, near Sonora, is being reopened for the resumption of work, after an idleness of several years. Local men are supplying the capital and Fred Launer, an experienced miner in these parts, will direct operations.——The Pine Log Mining Co. which will work a bar on the south fork of the Stanislaus river near the mouth of Five Mile creek, has been hauling machinery to the property, and expects to begin work soon.——Marble of high quality has been discovered on the Bell property, near Columbia, and exploration work has commenced. The property is in the hands of E. Hill and J. Warren.——An electric hoist is to be installed at the Faxon mine, north of Sonora, operated by F. A. Burgson and F. R. Restano. The old shaft on the property has been abandoned and a new one started. Now 80 ft. deep, it will be sunk an additional 50 ft., when a cross-cut will be started toward the old workings.——The Stanislaus Gravel Mining Co. has suspended operations at the If I Can mine, situated on Table mountain. It is understood that one of the principal owners will resume mining activities in the near future.

Sonora, April 21.

At a point 4011 ft. from the portal of its adit the Springfield Tunnel & Development Co., near Columbia, has opened rich gravel.

Commencing May 1, the Dutch-Sweeney Mining Co., W. J. Loring general manager, will raise miners and certain surface mens' wages 25c. per shift. This was voluntary.

COLORADO

Boulder County

The U. S. Tungsten Co. has acquired the properties of the Colorado Tungsten Co., near Nederland, for several hundred thousand dollars. The former concern is a new corporation, organized by T. E. Foley, J. B. Ross, and others of Denver, and W. M. Long of Boulder, with a capital of $1,250,000. High-grading tungsten ore is rampant in the district and arrests are reported.

Gilpin County

This county is being searched for tungsten ore, and good ore is reported from Apex and Hughesville mines.

Lake County (Leadville)

Wolframite and scheelite is the subject of a paper by R. S. Fitch and G. F. Loughin in *Economic Geology* for January. The latest of the many types of orebodies to be identified here is that of gold-bearing quartz-pyrite veins containing these tungsten minerals. The ore mined is from some leases on the Ibex and adjoining properties to the south, on Breece Hill. The daily output of ore, assaying 0.8 oz. gold and 0.5 oz. silver, is 200 tons. The country-rock near the shoots includes Weber grit and gray porphyry, and the veins may cut both. Tungsten minerals are distributed throughout the zone of higher-grade ore, persisting downward with the shoot, their quantity increasing with depth. Scheelite is more abundant on the upper levels, wolframite on the lower. It is probable that the tungsten veins at Leadville represent a transition stage between contact-metamorphic deposits and the gold-silver sulphide veins.

San Juan County

A wide vein of high-grade hübnerite has been found in the Ruby and Cascade mines in Maggie gulch near Silverton.

After several years' idleness the Kittimac mill is again in operation. Treatment includes the Huff electro-static process and flotation.

Teller County (Cripple Creek)

Forty tons of ore, worth $1 per pound, was recently shipped from the Cresson mine to the Golden Cycle mill at Colorado City.

In March the Vindicator produced 12,621 tons of ore, lessees contributing 6302 tons. Electric pumps are being installed at 2150 ft. in the Golden Cycle mine. The Vindicator has paid its last note for the purchase of the Golden Cycle mine, $1,250,000.

There were no bidders at Colorado Springs on April 25 for the properties and plants of the U. S. R. & R. Co. in this State. The minimum price has been reduced to $200,000, and another sale was to be held on May 2.

"The Lure of Cripple Creek Gold" is the title of a 48-page booklet published by Wm. Y. Seaman. "Hundreds of millions" ($354,764,653), is the output to the end of 1915, of which shareholders received $51,888,684. The first dividend-payer was the Pharmacist, located by a drug-clerk. Mary McKinney stock was once traded for groceries and supplies around the town. It has produced nearly $9,000,000 since. To 'Bob' Womack should be given credit for the first discovery in the district, in 1890. The name "Cripple Creek" is believed to have sprung from the fact that many of the grazing cattle had their legs broken in Womack's prospect holes. The split-check leasing system, now used in many States, originated at Cripple Creek. Three Irish-Americans discovered the Portland. Stratton's Independence was the first great mine of the district. The Cresson was a despised prospect, but disproved that term by its fabulous vug in 1915. Gigantic strides have been made in mining and metallurgical work. What of the future?

These are some of the interesting points discussed in this little work.

IDAHO

Shoshone County (Coeur d'Alene)

An order, returnable April 29, has been issued by Judge W. W. Woods of the district court of this county, at Wallace, summoning the officials of the Success Mining Co., operating in the Nine-Mile district, to show cause why they have refused to permit shareholders to examine the contract they are alleged to have entered into with the Grasselli Chemical Co. of Cleveland, Ohio, for smelting the output of the Success property, effective from May 1. Settlement rates are alleged to be unfavorable.

The Board of Trade of Wallace is considering appealing to the Northern Pacific Railway company to extend its line up Nine-Mile creek into the Beaver Creek region through a tunnel to be driven at Dobson pass. This, it is thought, will divert the business and traffic of the rapidly developing Beaver Creek district to Wallace, which now stands a good chance of losing this trade. The Ray-Jefferson, Interstate-Callahan, Idora, and Tuscumbia companies' operations suggest that this work be done.

The Coeur d'Alene Antimony Co., operating near the mouth of Pine creek, is under new management. Electricity is to supersede steam, a flotation plant is to increase the present 65% recovery of the antimony.

The first unit of the Empire Copper Co.'s new mill on the little north fork of the Coeur d'Alene river will be ready in three weeks. It will be of 300-ton capacity. In the mine is 100,000 tons of 3.2% copper ore.——A Spokane syndicate, headed by F. J. Finucane, president of the Holly-Mason Hardware Co., has purchased control of the Alameda Mining Co., which has a group of claims adjoining the Success holdings in the Nine-Mile district. The ore contains lead, silver, and zinc.——F. C. Bailey of Spokane has taken a year's option on the treasury stock of the Placer Creek Mining & Milling Co., about 400,000 shares, and 50% of the issued stock. The contract specifies that Mr. Bailey is to keep the property under continuous development during the life of the option, the Placer Creek company to furnish the equipment. The property consists of five claims, six miles up Placer creek from Wallace.

MICHIGAN

The Copper County (Houghton, Etc.)

(Special Correspondence.)—No event of recent copper mining interest in the Lake Superior region has attracted more attention than the announcement of the purchase of control of the Seneca by Thomas F. Cole and associates. It means immediate development work on a large scale, as Mr. Cole has announced that $1,000,000 is to be spent to make Seneca a commercial copper producer on the Kearsarge lode. The Seneca is admirably situated, being near the Ahmeek and Mohawk. The area is 1800 acres. No work has been done for six years. The Calumet & Hecla company owned 11,270 shares in the Seneca, and holders approve of the transaction.

Houghton, April 18.

It seems likely that the Tamarack will be sold to the Calumet & Hecla for $59 per share, as so far holders of over 25,000 shares have assented to the proposal.

Later news states that the voting was 48,870 shares in favor, against 479 in opposition to selling the mine.

MISSOURI

Jasper County

Ore prices were easier at Joplin last week. The Missouri-Kansas-Oklahoma region produced 9148 tons blende, 672 tons calamine, and 1267 tons lead, averaging $105, $76, and $99 per ton, respectively. The total value was $1,138,020.

Better recovery of metals is the slogan in the district, and slime plants are being added to many mills. The Dorr thickener is used by the Picher Lead, Commerce, American Zinc, Granby, and other well-known companies.

MONTANA

Silverbow County (Butte)

At 2500 ft. in the Davis-Daly there is 400 ft. of 6% copper ore, over a width of 8 feet.

During March the Butte & Superior produced 12,199 tons of zinc concentrate from 52,089 tons of ore. The concentrate was valued at $93.62 per ton. In the suit of the Elm Orlu *v.* the Butte & Superior, Judge Bourquin has awarded the former 31,805 tons of ore assaying 20.5% zinc and 6 oz. silver per ton.

The Bertha mine has been unwatered by the Boston-Corbin company. The workings are 1200 ft. deep. Ore will soon be extracted.

By order of the Court at Butte one of the creditors of the Butte-Duluth company has permission to sell part of the equipment through the receiver.

NEVADA

The report of the Nevada-California Power Co., which has hydro-electric plants near Bishop, Inyo county, California, and supplies Goldfield, Tonopah, and other mining centres of Nevada, as well as southern California, shows that the operating revenue in 1915 was $899,562. The operating profit was $367,553, plus $80,695 from sundry sources. Interest absorbed $197,324, and dividends $200,000.

Esmeralda County (Goldfield)

Final figures of the Goldfield Consolidated for March show a net realization of $54,128 from 30,000 tons of ore. Costs totaled $5.48 per ton. Development covered 3041 ft., at a cost of $5.58 per foot, but revealed little of importance. The 500-ton flotation plant is to be increased to 1000 tons, for which plant has been ordered.

In the Silver Pick Consolidated, the Calyx core-drill working from the 700-ft. level, has cut the shale at a depth of 1000 ft. At the latite-shale contact assays as high as $50 per ton are reported. This is of importance, and the shaft will be sunk 300 ft. to reach the contact.

The annual report of the Atlanta Mines Co. states that the output was 1832 tons of ore worth $30,115, yielding $13,022 net, from the shoot above the 1750-ft. level; also 1212 tons of ore worth $6214 net from the Grizzly Bear claim. The ore-shoots are irregular, and not enough has been developed to warrant erecting a mill, yet ore might be sent to the Goldfield Consolidated or Nevada Metal Extraction plants for treatment. Mine development cost $97,590. The debt is $85,343.

Humboldt County

The advance in price of silver makes an increase of $5000 in the monthly output of the Rochester Mines Company.

The old Humboldt Queen silver mine, 7 miles north-east of Oreana, has been re-opened and is producing ore. It was closed in 1873.

Lincoln County

According to the report of the Prince Consolidated Mining & Smelting Co. of Pioche for 1915 the output was 119,003 tons of ore, etc., giving a revenue of $313,019. Ore reserves, partly opened, are estimated at 6,156,000 tons, occurring in four 'beds,' the 90, 20, 5, and 12 ft., an average aggregate thickness of 120 ft. The ore is a manganese-iron, containing silver, lead, and gold. The operating profit was $158,554. Dividends absorbed $124,924. Assets amount to $106,637. To treat 120,000 tons of gold-silver-lead tailing at Bullionville, a $40,000 flotation plant is to be erected.

Mineral County

It is said that tin in commercial quantities has been found in the tungsten deposits near Sodaville. This was detected during concentration.

Nye County

In the week ended April 22, Tonopah mines produced 8334 tons of ore valued at $175,272. Some March returns were as follows:

Belmont: 272,077 oz. bullion from 13,120 tons, with $105,478 profit. Extension: 184,420 oz. from 7521 tons, and $78,246 profit. Jim Butler: profit of $24,678 from 3166 tons.

White Pine County

(Special Correspondence.)—The Nevada Scheelite Co., a Utah incorporation, has been recently formed with directors and officers as follows: A. W. Gates, president and secretary; E. R. Pembroke, general manager; George R. Sheldon and W. J. Stewart, completing the directorate. One of the objects of this company is to take over 20 claims in the Minerva district and develop the large tungsten veins thereon. On a recent visit to the property, the manager saw the completion of the company's first camp, and outlined the establishment of a second which is now well under way. About 15 men are at work at the property at this time, and this company expects soon to enter the active list of producers of tungsten ore.

Salt Lake City, April 22.

On April 21 four tons of tungsten concentrate worth $25,000 was shipped by express from Ely by the U. S. Tungsten Corporation, operating at Tungsten, 45 miles east of Ely. The buyer was the Midvale Steel Co. of Pittsburg, Pennsylvania. The company is in the market for tungsten ore containing over 3% delivered at Tungsten. In a published schedule of wages this company's lowest is $4 per day for surface labor and shovelers.

Discoveries of tungsten ore are reported from many districts, a recent one being 15 miles east of Ely, the mineral being ferberite. Another was scheelite in the Cherry Creek district.

The property of D. Simonson and H. Ashley in the Tungstania district has been purchased by C. Osterlund of Ely for $20,000.

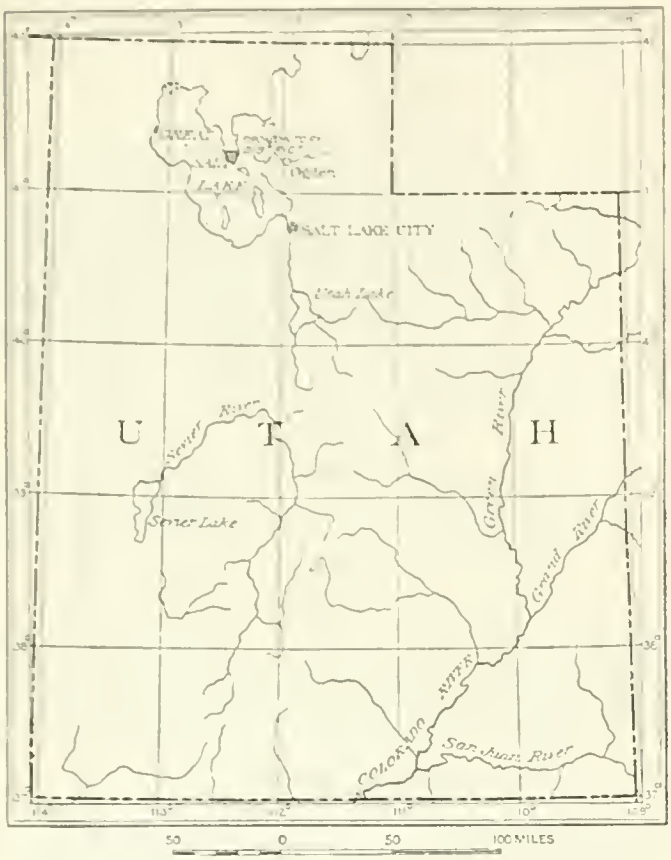
Good reports come from Weaver Creek, six miles east and south of Osceola.

Ely is optimistic as to its future, depending on the adjacent copper and tungsten regions.

UTAH

Honeyer County

In Bulletin 640-A of the U. S. Geological Survey, R. S. Butler and V. C. Heikes give notes on the Promontory district, where operations of the Lake View Mining Co. attracted considerable attention in 1915. Present activity is confined to the zinc-lead deposits, which are found in the middle limestone bed. This bed is 50 to 75 ft. thick. Included in members composed prevailingly of shale. Shipments of ore



MAP OF UTAH, SHOWING THE PROMONTORY ZINC DISTRICT.

average 32.75% zinc and 7.7% lead. Some copper occurs in the district, near Great Salt Lake. The ore is disseminated in quartzite.

Summit County

To lease the American Flag mine below 1000 ft., the Park City Mines Co. has been organized. The Mines Development Co. has the mine from 1000 ft. to the surface.

WASHINGTON

Stevens County

The United Copper Co. at Chewelah is making regular shipments of copper ore and concentrate to Trail, B. C. The crude ore assays 4.8% copper and 11.4 oz. silver, while the concentrate contains up to 13.24% copper and 31.9 oz. silver. The profit in April is estimated at $25,000, while May should give nearly $40,000. The debt has been reduced to $71,054.

CANADA

British Columbia

The first unit of the Consolidated Mining & Smelting Co. of Canada electrolytic zinc refining plant at Trail, is in commission, and the remaining eight units are being installed as rapidly as possible. They probably will be in service in the next fortnight. The complete plant cost about $1,000,000. An electrolytic copper refinery to cost as much will be erected soon.

G. H. Short and W. B. Montgomery of the Grasselli Chemical Co. have been touring the province in search of zinc mines.

Four blast-furnaces at the Anyox plant of the Granby Consolidated are treating at the rate of 80,000 tons of ore monthly. The town of Anyox has a population of 1600 people. The Alice Arm district, at the head of a branch of Observatory Inlet, is attracting attention, there being 300 people, according to W. A. Williams of the Granby company. Goldfield Consolidated people have found high-grade silver-lead ore in the Dolly Varden mine by diamond-drilling. The town at the end of Alice Arm has a good hotel, stores, etc.

At its Hidden Creek property the Granby Consolidated is to construct an auxiliary hydro-electric plant of over 7000 horse-power.

Mining is being revived in the region tributary to Nelson, and several important deals have been closed recently according to a letter received by the Northwestern Mining News Service of Spokane from Fred A. Starkey of Nelson. A Victoria syndicate has taken a $75,000 bond on the Eureka group of copper-gold-silver claims on Eagle creek, a few miles west of Nelson, and a company is being organized to equip the holdings and operate them.

New interests have acquired the Vancouver gold claims, adjoining the Queen holdings in the Sheep Creek district, and extensive development already is under way. The bond is for $45,000, and the first payment of $5000 has been made. The Golden Fawn group, another Sheep Creek gold property, has been taken under bond by a Spokane syndicate for a reported price of $100,000. The California group of free-milling gold properties on the mountain overlooking Nelson has been secured by a local syndicate.

The Hudson Bay zinc mine near Salmo has been taken under control from M. W. Bacon and W. E. Cullen by Hayden, Stone & Co. of New York, for $2.50 a share. Lead ore was mined from the upper workings, while zinc carbonate has been developed to a large extent. Reserves are said to be 200,000 tons.

To haul ore from the Hudson Bay zinc mine near Salmo, a distance of 7 miles, caterpillar-tractors are to be used. The daily output is 100 tons. A lower adit is in 385 ft., to cut the vein at a depth of 1750 ft. This will be completed in August.

Ontario

During the first quarter of 1916 the McIntyre company at Porcupine treated 27,248 tons of $7.74 ore, at a cost of $3.85 per ton. The recovery was 95.4%.

At Cobalt the Beaver and Temiskaming shafts, being sunk to the contact with the Keewatin formation, are down 1500 and 1100 ft. respectively.

KOREA

The March clean-up of the Oriental Consolidated was worth $136,255.

On April 6 the Oriental Consolidated company paid a dividend of 50c. a share. The January output was $144,932 from 26,806 tons of ore. Recovery in the Taracol cyanide plant was 90%, at the Maibong tube-mill 96%; both are giving excellent results.

MEXICO

At the annual meeting of the Exploration Company in London, the chairman, R. T. Bayliss, made the following statement concerning that well-known British company's operations in Mexico:

"As the disturbed condition of Mexico is the fundamental cause of all our trouble, I should like to give a short account of the conditions which have prevailed, and still prevail, in that unhappy country. Internecine strife has raged throughout the country for the past three years, and if it is not today so violent as it has been, it is not because the spirit of the

people is unwilling, but in consequence of the physical and economic exhaustion of the country. Throughout this period all our operations and those of our subsidiary companies have been hampered and hindered to a point which rendered anything in the nature of regular or profitable work impossible. The Santa Rosa company was compelled to shutdown three years ago, and nothing has been done upon the property since. The El Oro mine had to suspend operations for several months during 1914. It re-started, under compulsion, in September of that year, but had again to cease work in February, 1915, and has remained closed ever since. The Buena Tierra mine, although able to work intermittently during a portion of 1915, was unable to do so at a profit, and was compelled to suspend entirely in September last and is still idle. The Exploration Company of England and Mexico, which at the commencement of hostilities was developing into a prosperous undertaking, has not been able to do any business at all, and, in fact, practically one-third of our capital has been unproductive and in jeopardy during this period. This is a sorry tale to tell but I put the facts so in order that shareholders may realize that our present position is due to circumstances which we could not foresee and were powerless to control. For some weeks past fighting, except in a detached and undisciplined form, has for the moment practically come to an end. To this extent the position may now be said to be a little more definite, but it can hardly be described as improved. The economic and financial position of the Republic remains as bad as it can be. The treasury is bankrupt; gold and silver coinage has disappeared; the country is flooded with a fiat paper money which is not current in all parts of the Republic, and not at all beyond its borders. There is not any quotable international exchange, the rate on London having fallen nominally to 1½d (3c.) on the peso, compared with the parity of 2s 1d (50c.) and in consequence the business and industrial position in Mexico generally is in a state of chaos and disorder. In addition to all this, pestilence and famine have prevailed in Mexico City and outlying districts for some time. Even on the assumption, therefore, that no further revolutions interfere with the reorganization of industrial conditions, a long time must necessarily elapse before we return to conditions similar to those which prevailed during the effective administration of the late president Diaz, and at the moment I feel quite unable to make any forecast as to when our properties will be able to resume operations or the conditions that will be imposed upon us when they do."

SONORA

Every idle mine in this State must be re-opened by May 1 or pay a heavy tax to the Government, is the decree of the governor, P. Elias Calles. The rich silver mine near Arizpe, Las Chispas, would be fined ₱10,000 a month for two months if it remained closed, then the State would operate it for the benefit of employees. No property is to be confiscated. The case of Las Chispas is considered to be particularly flagrant, as the governor considers that large shareholders are trying to squeeze out smaller holders.

The recent addition of a thoroughly equipped microscopical laboratory for metallurgical research at the Salt Lake City station of the U. S. Bureau of Mines in connection with the co-operative work that is now being carried on between the Department of Metallurgical Research of the University of Utah and the Federal Bureau of Mines, gives Salt Lake City the best equipped microscopical laboratory for metallurgical research in the United States.

The U. S. Civil Service Commission at Washington, D. C., announces an open competitive examination for physical metallurgist on June 7. From the register of eligibles resulting from this examination certification will be made to fill a vacancy in this position in the Navy Yard, Boston, at a salary ranging from $6 to $8 per day.

PERSONAL

Note: The Editor invites members of the profession to send him particulars of their work and appointments. This information is of unquestioned interest to our readers.

L. D. RICKETTS was married on April 26.

D'ARCY WEATHERBE has returned to London.

R. S. BOTSFORD is in the Bodaibo district of Siberia.

A. E. DRUCKER has returned to New York from Panama and Jamaica.

ALEXANDER MCLEOD has been examining prospects in western Nova Scotia.

G. L. SHELDON of Ely, Nevada, has been in Washington county, Idaho.

ERNEST A. HAGGOTT has returned to San Francisco from Central America.

R. G. WAYLAND, superintendent of the Alaska Treadwell, is here from Treadwell.

C. E. KENNEY passed through San Francisco last week on his way to Los Angeles.

ARTHUR PECKHAM is assayer at the Dutch-Sweeney mine, in Tuolumne county, California.

C. T. DURELL passed through San Francisco on his return from Montana to Los Angeles.

FREDERICK HELLMAN, general manager of the Chuquicamata mine, of the Chile Copper Co., is here.

S. S. JONES has resigned as superintendent for the Tom Reed Gold Mines Company, at Oatman, Arizona.

C. T. GRISWOLD of the Associated Geological Engineers has returned to Pittsburg from south-western Montana.

BULKELEY WELLS and WILLIAM J. COX have been delegated to represent Colorado mining men in a protest against mining-law reform now before Congress.

W. H. MCKENNA is assisting his brother, J. A. MCKENNA, manager of the Vasco Mining Co. at Boulder, Colorado, in the purchasing and sales departments.

As we go to press, we are informed that R. T. BAYLISS, chairman and managing director of the Exploration Company, and of other important mining companies, such as the El Oro Mining & Railway Co., was struck by a bomb from a zeppelin on Friday, the 28th ult., in England. An arm had to be amputated and he is in a serious condition. Mr. Bayliss has many friends in this country, for he lived in Montana for several years and his honorable connection with American mining extends over thirty years, therefore this is bad news to many of our readers, as it is to us. We hope still, however, that his life may be saved by skillful nursing.

Schools and Societies

The School of Mines and Metallurgy, UNIVERSITY OF MISSOURI, at Rolla, has issued its Catalogue for 1915-'16. In the 149 pages are details of all pertaining to this institution.

The MASSACHUSETTS INSTITUTE OF TECHNOLOGY will dedicate its new buildings, and commemorate the 50th anniversary of its foundation, on June 12, 13, and 14. The colleges are on the Cambridge bank of the Charles River basin, near Boston. Many festivities are planned, and 11,000 old students and undergraduates are expected.

Thirty students and instructors from the College of Mines, UNIVERSITY OF WASHINGTON, took part in the annual spring excursion early in April. Studies were made of the new reverberatory and casting furnaces at the Tacoma smelter, the Du Pont powder works on Puget Sound, and the Britannia Mining & Smelting Co.'s mine and mills on Howe sound, near Vancouver, British Columbia. The Britannia mills are using Hancock jigs, Butchart tables and Minerals Separation flotation cells to get a high recovery on low-grade chalcopyrite ore.

THE METAL MARKET

METAL PRICES

San Francisco, May 2

Antimony, cents per pound	42
Electrolytic copper, cents per pound	31
Pig lead, cents per pound	$8.00—8.80
Platinum soft metal, per ounce	$85
Platinum hard metal, 10% iridium, per ounce	$89
Quicksilver, per flask of 75 lb.	$115
Spelter, cents per pound	22
Tin, cents per pound	50
Zinc-dust, cents per pound	30

ORE PRICES

San Francisco, May 2.

Antimony: 50% product, per unit, of 1%, or 20 lb.	$2.25
Chrome: 40% and over, f.o.b. cars California, per ton	12.50
Manganese: 50% metal, 8% silica, per ton	12.00
Tungsten: 60% WO_3, per unit of 20 lb.	60.00—65.00

Those interested in manganese should secure a copy of 'Manganese Ores of Brazil, Chile, India, and Russia,' a paper prepared by E. C. Harder for the Arizona meeting of the A. I. M. E. In the 38 pages is much valuable information.

New York, April 26.

Antimony ore continues in demand, and for ore afloat $2.75 per unit has been paid. It continues difficult to obtain ocean-freight space for shipments from South America.

EASTERN METAL MARKET

(By wire from New York.)

May 2.—Copper is quieter but strong; lead is dull with an easier tone, spelter is quiet though steadier.

SILVER

Below are given the average New York quotations, in cents per ounce, of fine silver.

Date.		Average week ending

Silver is advancing with great strides. London quotes 36 pence, the highest since December 1892. Stocks in London, April 3, were only 5,600,000 oz., since when 1,300,000 oz. arrived from New York. This metal is earmarked for definite purposes and is not available for re-sale. Supplies arrive slowly and when they do they are cleared off the market at each upward movement in price. Europe is a considerable buyer. Exports to India up to the 12th were £476,000, against £1,641,500 in that period of 1915, a decrease of, say, 10,000,000 ounces.

Butte copper companies have raised miners' and smelter-men's wages to $4.50 per day, an increase of 25c. This will be effective while copper is 25c. per pound or over. The monthly pay-rolls of the district now total $2,160,000 for 20,000 men.

Greene Consolidated is paying $1 per share, an increase of 50 cents.

Kennecott (Alaska property only) produced 63,000,000 lb. of copper in 7 months ended December 31, 1915. The cost was 4.51c per pound. The ore averaged 60.11%. On March 31, $1 per share was paid, equal to $2,780,583. After this was distributed, cash, cash assets, and copper were worth $13,600,000.

In San Francisco, on April 28, a public sale was held to dispose of 192 flasks of quicksilver. Among the 25 persons present, well-known dealers were represented, but the metal was bought-in by the owner, John McNear, at $105 each for 85 flasks, and $100 for the remainder, he being the only bidder. The proceedings had an appearance of unreality. The market is mysterious and the obvious victim of manipulation.

Eastern Metal Market

New York, April 26.

In marked contrast with recent weeks, the market is now quiet. Copper is the most active of the metals, but the big buyers are no longer eager to buy. Lead and zinc are positively dull. Copper prices have been maintained, but those of every other metal have declined. In seeking an explanation of the sudden dullness, the trade is pointing to the German-American complications, saying that business is not likely to revive until the proposals of the Administration seem clear again. But the best explanation is that there has been heavy buying of all the metals, and consumers cannot be expected to go on buying full tilt continuously. They must have an opportunity to digest their purchases. So far as the week is concerned, the Easter holiday—from Thursday to the following Tuesday—which was observed more particularly in London, made the market quiet on those days. In spelter an adverse influence has been exerted by the report of the U. S. Geological Survey, futures being most affected.

General trade conditions in the metal-working lines continue good, with the exception of an increasing number of strikes which are to be found in half a dozen States. The National Conduit & Cable Co., Hastings-on-Hudson, N. Y., which is a large user of copper, is grappling with a bitter strike, to handle which four companies of militia have been called out. It is feared that with the approach of May 1 strikes will become more general.

COPPER

Quotations continue strong, but the market has turned quiet to the point of dullness. In the past few days there have been offerings of spot electrolytic at 30.50c., full terms, but no acceptances. Re-sale metal has appeared in considerable quantity, and the story goes that some of it was bought on speculation by German interests. This, however, lacks confirmation. April and May deliveries of electrolytic have been offered at 30c., also without results. August and later deliveries of electrolytic are held at about 28.50c. cash, New York, but buyers are not interested. Lake for forward delivery is nominal at 28.75c., while up to 31c., is quoted for nearby positions. The dullness may be temporary, but on the whole it looks as if the market is in for a rest and eventually for lower prices. It is not to be expected that the heavy buying of a week or ten days ago could be long maintained. Exports from April 1 to 25 totaled 18,780 tons, but there are also to be considered the vast quantities which are going abroad in the form of munitions. The London market continues strong, the quotation yesterday being £140. Since the heavy buying subsided, reports have continued to appear in the daily press of the great business which, they assert, is still being done; but the trade figures that these stories originate in Wall Street and are founded on a desire to boom the stocks of the copper-producing companies. As a matter of fact these stocks have lagged far behind in proportion to the advanced prices of copper metal—just why is not clear.

ZINC

Though the spelter interests have held that the recent report of the U. S. Geological Survey did not constitute a bear argument, the report has nevertheless had the effect of making the market very dull. Futures in particular are very near unsalable, in view of the great prospective production which is predicted. Prompt zinc has dropped to 18.25c., New York, and 18c., St. Louis. The St. Louis minimum for May delivery is about 17.37½c.; for June, 16.75c., and for third quarter, 15.50c. Exports from April 1 to 25 totaled 2111 tons. The London market is unchanged at £103. The domestic situation can be summed up with the statement that it is weak and interesting. It has not been helped by efforts which a few consumers and speculators have made to sell. Sheet-zinc is quoted at 25.50c., carload lots, f.o.b. mill, 25% off for cash.

LEAD

The bottom appears to have dropped out of the lead market. Both foreign and domestic buyers are conspicuous only by their absence, and prices have declined. The New York quotation of the A. S. & R. Co., and those of the Independents are now on the same level, 7.50c. At St. Louis the Independents are quoting 7.37½c., although the leading producer adheres to 7.42½c. There is some pressure to sell. Some sellers are looking for business, but they are meeting with little success. The foreign demand is especially slow. It has been predicted that prices would decline if the foreign demand did not hold up. Last week a fairly round lot of Mexican lead that recently came over the border was offered in this market, but the best bid received for some time was 6c., in bond, New York. Later a better price was offered, and a part of the lead was disposed of. Consumers are well supplied and under the circumstances ask why they should bid any price. Exports from April 1 to 25 totaled 1270 tons. The London quotation yesterday was £34.

TIN

The week has been a quiet one. On no day was there any business of consequence until yesterday when two consumers came in the market, each wanting 100 tons. As a result, at least 200 tons was taken, all for future delivery. The obtaining of licenses to ship from London continues an uncertain matter. At the same time arrivals have been fairly large of late, and this fact, together with the lack of demand has caused quotations to decline. The quotation for spot yesterday was 49.75c. The consumption of tin in this country is great. Sales of tin-plate have been made at $5 per base box, at mill. Some good-sized foreign contracts have been booked at that figure. The specifications against contracts for tin-plate received by the American Sheet & Tin Plate Co. last week were the heaviest in its history. The arrivals of tin from April 1 to 25 totaled 2635 tons, and there was afloat on the latter date, 5014 tons.

ANTIMONY

The market has been quiet, and under the influence of pressure to sell, quotations have declined until 39.50c., duty paid, can be done for spot Chinese and Japanese grades.

ALUMINUM

No. 1 virgin aluminum, 98 to 99% pure, is quiet and slightly easier at 58 to 60c. per pound.

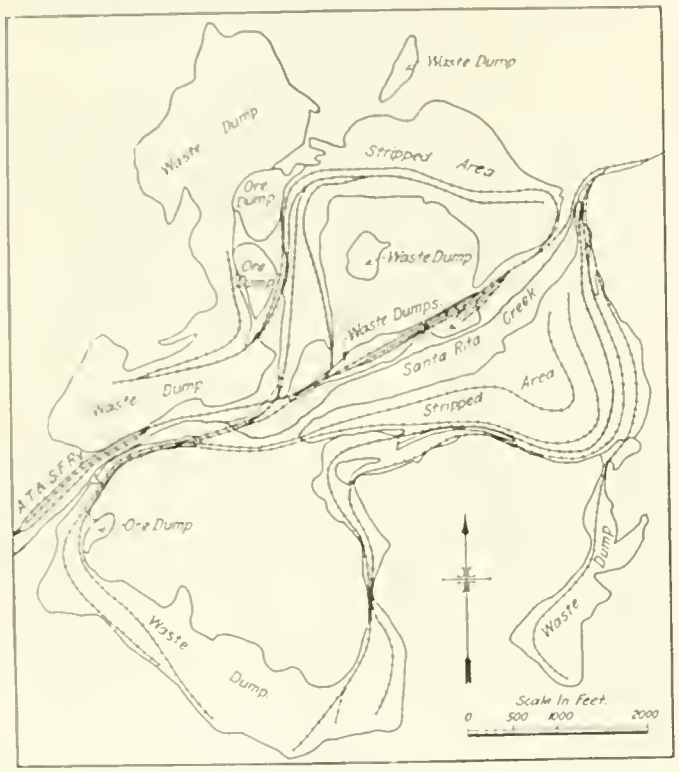
TUNGSTEN

A New York broker (Charles Hardy, 50 Church street) reported on April 25 as follows: Quotations for tungsten have experienced a heavy break during the past week. Most of the consumers have contracted for their immediate requirements and are holding off for future deliveries. The increased activity in this country and South America stimulated by the high prices, begins to show now in heavy arrivals from all quarters; and though Portugal is practically eliminated for the time being as an exporter, still enough is reaching this port. Holders of spot tungsten were most affected by the decline. Actual sales have been made for immediate delivery at $70 per unit, with buyers now below that figure. Forward tungsten is almost unsalable except at a huge discount. The break in tungsten, however, has had the effect of eliminating a good many speculators. Sellers will probably have to take a lower price in the future.

COMPANY REPORTS

CHINO COPPER CO.

The area of this company's property at Santa Rita, New Mexico was increased by 6 mining claims in 1915, making 153, equal to 2731 acres. Millsites, water-rights, etc., cover 18,568 acres more. Churn-drilling totaled 6909 ft., making 214,142 to date. This work will be continued when deemed desirable. Reserves remain at 90,000,000 tons of 1.75% ore. Overburden removed amounted to 3,133,916 cu. yd. The cost of steam-shovel mining this material and ore, 2,600,271 tons, was 35.2c. per ton. Mining the ore was 19.47c. The mill was at full capacity in April, and treated a total of 2,379,800 tons,



OREBODIES AND DUMPS AT THE CHINO MINE.

equal to 1304 tons per mill-unit (5) per day. The ore averaged 2.155% copper; 158,444 tons of 21.551% concentrate was produced; the recovery was 66.588%; and the cost was 54.19c. per ton. The yield of metal was 68,293,893 lb., produced at a cost of 7.12c. per pound, against an average of 17.42c. received. The year's revenue was $11,383,777; net profit, $6,913,984; dividends paid, $2,609,860; net surplus, $4,046,859; and total surplus, $8,613,261. The general manager is John M. Sully; superintendent of mines, Horace Moses; consulting engineer of mines, R. G. Gemmell; superintendent of mills, W. H. Janney; manager of mills, F. G. Janney; and cashier, George L. Webster.

MIAMI COPPER CO.

Accompanied by large photographs of its property the report of this Arizona company for 1915 is of value. The general manager, R. Britton Gottsberger, made the following remarks, in part:

Operations were curtailed in the first quarter, but by June the monthly output was 4,000,000 lb. of metal. Mine development covered 21,746 ft., 10,787 ft. being preparatory work in the Captain orebody, which is now supplying ore, over 2,000,000 tons being available so far. Shrinkage stoping is in vogue there. In the eastern part of the mine, which is of higher grade, topslicing is the system practised, and this is to be done at the 570-ft. level. Mining 1,353,122 tons cost $1.01 per ton, a reduction of 17c. Reserves are 35,140,000 tons averaging 1.82% copper, also 6,000,000 tons of 2% ore.

The mill treated 1,348,122 tons of 2.17% ore, with 75.17% extraction (an increase of 5.24%), at a cost of 57.94c. per ton. There was 52,539 tons of 41.91% concentrate produced. Several improvements were made to the mill, and experiments are being continued.

The refined copper produced was 41,832,059 lb., at a total cost of 8.76c. per pound, against 17.33c. received. The operating cost was $1.8785 per ton of ore. The revenue was $7,262,884, of which $3,589,680 was profit. Dividends absorbed $1,681,004. The year commenced with a balance of $1,147,788 and ended with $3,175,346.

The assistant manager (in charge of mining) is F. W. Maclennan; mill superintendent, F. W. Solomon; and assistant at the mill, Ralph B. Yerxa.

NEVADA CONSOLIDATED COPPER CO.

Recoverable developed ore in this company's property was estimated at 50,525,289 tons, averaging 1.652% copper, at the end of 1915, an increase of 9,504,993 tons, although the previous total contained 0.028% more metal. Churn-drill prospecting amounted to 17,779 ft., in the Ruth, Eureka, Liberty, and Hecla mines. The total to date is 124,316 ft. Stripping removed 2,758,350 cu. yd. of capping, at a cost of 28.87c. per yard, a reduction of 2.84c. The charge for steam-shovel mining was 15.24c. per ton.

The mill treated 3,081,520 tons of ore, averaging 1.54% metal, with 70.18% extraction. At the smelter there was reduced 573,873 tons of material in the reverberatories, 348,377 tons coming from the roasting plant. The converters yielded 62,520,855 lb. of company metal, and 1,785,011 lb. from custom ore, at much lower cost. The price received for copper was 17.647c. per pound, and the cost was 8.67 cents.

Revenue from metals (gold and silver, $615,606) was $11,685,277. The operating profit was $5,140,683, plus $764,918 from miscellaneous sources, a total of $5,905,602. Dividends (4) amounted to $2,999,185. The year ended with a balance of $4,849,556, against $2,290,626 in 1914.

The staff is as follows: general manager, C. B. Lakenan; general mine superintendent, Robert Marsh, Jr.; shovel-pit superintendent, E. E. Vanderhoef; underground mine superintendent, W. S. Larsh; smelter superintendent, R. E. H. Pomeroy; concentrator superintendent, George C. Riser; business manager, C. V. Jenkins, and consulting engineer, Pope Yeatman.

RAY CONSOLIDATED COPPER CO.

The 1915 report of this Arizona company is brief and concise. No development was done to prove additional ore, but underground work necessary for mining amounted to 45,292 ft., a decrease of 15,323 ft. Reserves are estimated at 71,911,475 tons of 2.235% ore. Other ore beside this will be opened later on. There was extracted 2,854,314 tons, 90% of which was from reserve drawing, 6% from stoping, and 4% from development, at a cost of 58.97c. per ton. Broken ore amounts to 3,000,000 tons. Coarse crushing cost 3.71c. per ton.

The mill treated 2,848,969 tons of 1.673% ore with 64.11% recovery, at a cost of 50.86c. per ton. From concentrate and some ore smelted direct the yield was 61,114,514 lb., against 58,020,955 lb. in 1914. The cost of producing metal was 9.423c. per pound, and the average received was 17.352 cents.

Income from metals totaled $10,498,962, of which $4,373,371 was profit. Adding sundry revenue and deducting interest, the net profit was $4,589,143. Dividends paid were $1,872,319. The surplus is $6,434,704, against $3,776,368 at the beginning of the period.

Operating officials are L. S. Cates, general manager, W. S. Boyd at the mine, D. D. Moffat at the mill, and R. I. Ezell cashier. The consulting engineer is R. C. Gemmell, and manager of mill F. G. Janney.

UTAH COPPER CO.

During 1915 this company treated 8,494,300 tons of 1.434% ore at a cost of 86.24c. per ton for steam-shovel mining, railroad transport (26 miles), and milling. The metal yield was 156,207,376 lb. In 1914 the tonnage was 6,470,166, costing 95.5c. per ton, producing 121,779,401 lb. of copper. The revenue from 148,397,006 lb. copper at 17.679c. per lb., 36,760 oz. gold, and 371,712 oz. silver amounted to $27,155,944. The operating profit was $15,023,834, plus $2,896,609 from investments, etc. Dividends amounted to $6,904,083. The balance from 1914 was $13,035,409, while that carried forward to 1916 was $23,498,074. Metals on hand and in transit are valued at $8,675,199, supplies on hand $736,022, and cash $3,160,245. Current liabilities total $2,115,443. The cost of producing copper was 7.48c. per pound.

Development at the mine consisted of 1365 ft. of churn-drilling. The average calculated thickness of the orebody was increased from 465 to 480 ft. Reserves are 346,315,300 tons of 1.446% ore. This is an increase of 3,815,300 tons above the quantity mined, namely, 8,494,300 tons. Overburden removed was 5,961,367 cu. yd. All ore was extracted by steam-shovel, and the cost of mining was 24.41c. per ton, including 7.5c. for stripping, and 0.3c. for development, a good decrease compared with the charge in 1914.

The Arthur and Magna mills treated 3,261,000 and 5,233,300 tons respectively of 1.434% ore, with 64.13% extraction, and a cost of 34.02c. per ton, a small decrease. Low recovery was due to crowding the capacity and the copper carbonate interfering.

The Bingham & Garfield railway, between the mine and smelter at Garfield, carried 19,382 tons of freight daily also 97,304 passengers during the year.

Operating officials are as follows: general manager, Robert C. Gemmell; superintendent of mines, J. D. Shilling; chief engineer of mines, H. C. Goodrich; general superintendent of mills, F. G. Janney, Jr.; in charge of Arthur and Magna mills, T. A. Janney and H. C. Smith; assistant secretary, John M. Hayes; and assistant purchasing agent, C. F. Jennings.

AMERICAN ZINC, LEAD & SMELTING CO.

At the beginning of 1915 this company, with its mines and mills in Missouri, Tennessee, and Wisconsin, and smelters in Kansas, had notes payable of $1,130,000 and a bonded debt of $549,000. The notes were paid off, the bonds converted into stock, and a net deficit in quick assets of $643,452 changed to a net surplus of quick assets of $3,668,707. This is the result of the higher prices for zinc. The total profit was $5,293,878. The balance carried to surplus was $2,651,501. It is found necessary to use this in the business, so that cash dividends cannot be paid just yet, but it is proposed to issue one-third of the authorized capital as preferred shares, to be entitled to a cumulative dividend of $6 per share per annum, etc.

During the year the Mascot mine's capacity was increased from 1200 to 2200 tons per day. A 700-ton mill was erected at the Roseberry near by. New kilns and zinc furnaces were built at Caney, Dearing, and Hillsboro. At Joplin all the properties were worked. A large roasting and magnetic plant was constructed in Wisconsin. Nearly 8000 tons of Butte & Superior concentrate is reduced each month.

BUTTE & SUPERIOR COPPER CO.

If the shareholders of this zinc-producing company approve, the word 'copper' is to be deleted and 'mining' inserted in the name. The past year's operations were interesting from the great profits made, and the litigation with the Elm Orlu Mining Co. over certain orebodies. Zinc concentrate is treated by the American Zinc, Lead & Smelting Co., the American Metal Co., the U. S. Steel Corporation, and the U. S. Smelting Co. In the case of the A. Z. L. & S. Co. and the U. S. S. Co., the spelter produced is returned to the Butte & Superior, which sells its own metal. Spelter averaged 13.054c. per pound at East St. Louis, against 5.08c. in 1914. June 1915 averaged 21c.

The past two years' results compare as follows:

Income from zinc and lead concentrate and residues	$13,244,133	$4,037,674
Less freight	1,157,016	799,260
	$12,087,117	$3,238,414
Operating charges	3,012,965	1,845,502
Net profit (with sundries)	$ 9,125,947	$1,417,128
Balance from 1914	2,020,133	
Total available	$11,146,080	
Dividends paid (four of 75c. each and $14 extras)	4,908,115	
Balance for 1916	$ 6,237,965	

Shipments in transit are valued at $2,908,802 and cash on hand $2,128,187. Current liabilities total $606,317.

During 1915 the main shaft was sunk to 1900 ft., preparatory to opening the Black Rock orebodies at 1700 and 1800 ft., and opening the 1600-ft. level for ore extraction. The last mentioned is opened for 700 ft., with excellent results. Reserves are practically the same as in 1914, namely, 1,000,000 tons. There was mined 522,949 tons of ore at a cost of $3.36 per ton.

The mill treated 522,300 tons of ore, averaging 17.02% zinc and 7.63 oz. silver at a cost of $1.75 per ton, details of which were given in this journal of April 29.

The staff at Butte consists of J. L. Bruce, manager; F. G. Janney, manager of mill; J. T. Shimmin, mill superintendent; Angus McLeod, mine superintendent; and Charles Bocking, cashier.

CALUMET & ARIZONA MINING CO.

During 1915, this company, which owns 2000 acres in Cochise county, Arizona, absorbed entirely the Superior & Pittsburg Copper Co., which it controlled, resulting in no duplication of work and less taxes. The C. & A. also controls the New Cornelia Copper Co., which is developing and erecting a mill at the great mine at Ajo, Pima county; also the Tucson, Cornelia & Gila Bend Railroad Co., whose new line commenced service to the new mine on February 20, 1916. The year 1915 commenced at 50% capacity for the C. & A., but prospects for 1916 are the best reported. Four dividends amounted to $2,006,557. Total income was $11,683,724, and net $5,453,882. Assets at December 31, 1915, included accounts receivable, $577,749; supplies, $334,274; cash, $2,561,931; and metals in process, $3,688,841. Liabilities included accounts payable, $224,548.

The general manager, J. C. Greenway, reported that development totaled 93,788 ft., an increase of 20,995 ft. Diamond-drilling amounted to 8975 ft. Water pumped was 1,927,516,900 gal., or 3667 gal. per minute, of which 1860 gal. came from the 1800-ft. level. Air made totaled 2,528,590,800 cu. ft. Results at the Junction and Briggs shafts were encouraging, especially at 1300 ft. in the former. A safety department was organized in April.

The smelter reduced 664,152 tons of company and 159,250 tons of custom ore. Two blast-furnaces treated 461,383 tons, and three reverberatories 333,541 tons. Ten roasting furnaces treated 283,349 tons of ore averaging 28.9% sulphur, reducing this to 9.5%. The converters produced 38,027 tons of blister copper. The metal production from company ore was 63,126,931 lb. copper, 947,129 oz. silver, and 26,213 oz. gold.

RECENT PUBLICATIONS

Zinc and Lead Handbook, 1916. By L. L. Wittich. P. 90. Map. *Joplin News Herald*, Joplin, Missouri. For sale by the Mining and Scientific Press. Price, 25 cents.

The author of this useful booklet is mining editor of a live paper in the largest zinc centre of the country, and correspondent of the Press, and is also conversant with events in the Missouri-Kansas-Oklahoma region, the output of which in 1915 was $26,038,650. The book contains in tabulated form spelter and lead production, prices, consumption, smelters, etc., of the United States and foreign countries; output, costs, and other statistics of the Joplin district, as it is known. Generally a handy little reference.

INDUSTRIAL NOTES

The Brown Hoisting Machinery Co. announces the appointment of its vice-president, Alexander C. Brown, to the position of general manager, succeeding Richard B. Sheridan, who has resigned to accept another position.

The Sullivan Machinery Co. announces the resignation of Robert J. Raley as district sales manager at Duluth for the Lake Superior iron and copper ranges. John F. Berteling, hitherto associated with Mr. Raley, succeeds him as district sales manager, with headquarters at Ishpeming, Michigan.

The Deming Co., Salem, Ohio, has recently published a general catalog which is above the average. In addition to listing various types of pumps for mine and mill work, together with their specifications, a quantity of technical data and engineering data and engineering tables are published showing capacities, air-compression, loads, friction of water, measurements, etc.

The Pratt-Gilbert Co., Phoenix, Arizona, has recently secured the representation of many Eastern manufacturers of mining machinery and supplies. Their lines include pumps, compressors, drills, hoists, packing, belting, drill-steel, etc. The stock is said to be sufficiently comprehensive to supply any of the probable demands of the mining districts of Arizona and New Mexico.

An express shipment weighing 13,000 lb., consisting of one 'Chicago pneumatic' air-compressor and four 'Hummer' hammer-drills, was recently made to New York by the Chicago Pneumatic Tool Co., 1010 Fisher building, Chicago, consigned to the International Trading Co., New York, which will reship these machines to South America, where they are to be used in the construction of sewerage systems and water-works in the cities of Paysanda, Mercedes, and Salto in the republic of Uruguay.

After a considerable amount of experimenting, Sill & Sill of Los Angeles, who purchased the Parks Electro-Cyanide Co., have been successful in making almost complete precipitation from solutions. The process is said to eliminate filtering devices and zinc precipitation, by amalgamating gold directly from cyanide solution and regenerating the cyanide. Highly mineralized ores are reported to be amenable to the system of treatment, which briefly consists of agitating pulp in a pan with cyanide solution in the presence of an electric current. The precious metals dissolved are then deposited on an amalgamated copper plate by the current.

The Justrite Manufacturing Co. of Chicago has completed its new factory building at Southport avenue and Kingsbury street, which will be the new home of the company. This building is four stories high and contains 50,000 sq. ft. of floor-space. It is of modern construction, with doors, stairs, and window-framing all of steel. Automatic sprinkling apparatus has been installed throughout the new plant. The principal business of this company is the manufacture of acetylene miners' lamps, of which they make a large variety. The acetylene lamp is rapidly taking the place of oil lamps and candles. It is estimated that at least 75% of all mining industries in this country use the carbide lamp for lighting purposes. The Justrite lamp is used extensively in this country, and the company is also enjoying a large export business. They also make fire-prevention devices and automatic sanitary-waste receptacles.

EDITORIAL

T. A. RICKARD, Editor

SAPONIFICATION, at one time, was suggested as an essential to successful operation of the flotation process. More than one patent was secured for the purpose. We publish an article by Mr. M. H. Thornberry, of the School of Mines in the University of Missouri, describing a series of experiments, designed to try the substitution of soap for oil as a frothing agent.

ANACONDA'S production in April is announced as 33,300,000 pounds of copper, an increase of 6,700,000 pounds above the output in March. In 1915 the production of the company at Anaconda and Great Falls was 254,311,574 pounds, as against 223,720,292 the previous year. Out of these totals, 19,235,285 and 18,421,761 pounds, respectively, represented copper extracted from custom ores. Out of the total production of silver in 1915, namely, 9,005,617 ounces, the company's mines contributed 8,064,986 ounces, together with 106,702 ounces of gold. In the annual report we find the significant statement that "the resumption of peace in Europe will, with perhaps a brief intervening period of re-adjustment, be accompanied by an enormous demand for copper, when industrial activity is resumed and the work of rehabilitation is undertaken."

IN statistics just issued by the Geological Survey, the total output of American copper in 1915 is given as 1388 million pounds, as compared with 1150 million pounds in 1914. Arizona was easily the biggest producer, contributing 432,467,690 pounds, Montana and Michigan ranking next with 268,263,040 and 238,956,410 pounds respectively. Last year Michigan regained the third place, passing Utah, which produced 175,177,695 pounds, increasing only 15 million pounds, while Michigan increased 81 million pounds during the year. Alaska made a big jump, from 24,985,000 to 70,695,000 pounds, passing both California and Nevada, this quadrupling of the output from the North being due chiefly to the relatively small tonnage of very rich ore from the Bonanza orebody of the Kennecott Copper Company. The most significant figure in the statistics is the increase of new refined copper, this being about 100 million pounds in excess of 1914, in which year the total was 1,533,781,394. It is probable that the refinery production will reach 2000 million pounds for the current year. This would be an increase of 27% over 1915, as compared with the 7.4% increase during the preceding twelve months. That 7.4% increase is only a little above normal, while the anticipated 27% for 1916 will be nearly four times the normal. And it will be produced on an average price 10 cents higher than in 1915 and nearly double the normal quotation for the last 30 years. The foreign copper refined in this country totaled 246 million pounds, including that from two American-owned Chilean producers, the Braden and Chile companies, the latter owning the Chuquicamata mine; also the Cananea output, from Mexico. Elsewhere we quote a forecast, appearing in the Anaconda annual report, in regard to the demand for copper after the War. It is to be noted that the German consumption of copper imported from America more than doubled between 1909 and 1913; how much of that was accumulated in preparation for *Der Tag* we do not know; nor where Germany is now obtaining her supply of copper: nor to what extent it has proved possible to substitute other metals for copper in the manufacture of both munitions and industrial products. These unknown factors may prove of small consequence in shaping the course of the market at the close of the War, but they must not be ignored by the student of economics.

DISCUSSION this week is enriched by the letter from Mr. Albert Burch on the training of the young American miner. We discuss the subject at length on another page. Mr. A. G. Harbaugh, an experienced mill-man, gives an account of the saving of the precious metals by amalgamation with the mercury precipitated from solution in cyanide. The relation of mining engineers to business, and particularly the advantage to the former of understanding the latter, is emphasized by Mr. P. B. McDonald, of our staff. The statistics of gold production are discussed by Mr. Edward Walker, of *The Mining Magazine*, with particular reference to our recent criticism of the figures published by two of our contemporaries. In a letter from Burma, Mr. William Kitto, of the Burma Mines Co., records his experience in the use of the light water-hammer drill and takes exception to sundry generalizations made by Mr. E. M. Weston, a South African engineer. The effects of flotation-oil in cyanidation have been tested by Mr. J. E. Clennell, of the Butters laboratory, and he writes giving the results of his research. This shows that the decomposition of cyanide, by such oil, is negligible.

MERCURY is a metal of particular interest at this time. We publish a useful article by Mr. Herbert Lang, who to long metallurgical experience adds the happy faculty of writing clearly and pleasantly. His treatment of the subject will please both those who know a great deal and those who know next to nothing in regard to this particular technical process, for he discusses the fundamental principles that are of equally vital im-

portance to the student and the specialist. On one minor matter we may venture to comment, namely, the presence of mercury in gold and silver ores. At Kalgoorlie, in Western Australia, an impure telluride of mercury called kalgoorlite is associated with free gold and various gold-silver tellurides, such as calaverite, sylvanite, and petzite. This kalgoorlite contains 11% mercury, while the true mercuric telluride, coloradoite, which was first found in Boulder county, Colorado, contains when pure 61.5%. In roasting gold precipitate from the cyanide plants at Kalgoorlie, some of the mercury used to be collected, notably in the Oroya-Brownhill mill. Mercury also occurs in association with silver at Cobalt, Ontario, as was pointed out recently by Mr. G. H. Clevenger, in *Economic Geology*. At the Nipissing the ore contains from 0.26 to 4.74% mercury, the maximum being found in mass silver or 'metallics.' In this ore the mercury exists as a silver amalgam, not so much with the purer forms of silver as with dyserasite, the antimonide of silver. Mr. Lang refers to several other unusual mercuric associations, all of which are of minor importance as compared with cinnabar, the principal ore, which in its purest form is the vermilion of the artist and the ancients.

FINE GRINDING, and the choice therefor between the stamp-battery and the ball-mill, is the subject of a suggestive article by Mr. Henry Hanson. 'The Passing of the Stamp' has been the title of technical ruminations for the time of a generation, yet the old machine, continually modified and improved, still lingers. Its place in the reduction plant has become more nearly fixed and the part it is called upon to play in the reduction process has been more nearly defined; nevertheless, the simplicity of the stamp-battery has caused it to survive amid the great diversity of apparatus devised during the last two decades. Undoubtedly the experience in the concentration of copper ores is exerting a big influence upon the vogue of the stamp in the metallurgy of the precious metals. It has long been recognized that the work done by the stamp in pulverizing ore to anything finer than, say, 30-mesh, is uneconomical; not only is the consumption of power excessive, but the product contains a disproportionate amount of slime. That is why the copper mills substituted rolls and stage-crushing. Concurrently, experience in the treatment of the hard gold-bearing banket of the Rand has shown that the finer grinding could be done best in other machines, so that there the stamp is now used only in reducing to 8 or 10-mesh, the final reduction being relegated to tube-mills. Now that slime has ceased to be such a bugbear and the adoption of flotation calls for intense comminution, we must revise our notions on the subject. Other factors, such as space occupied, power consumed, and water wasted, have come into play against the stamp-mill, and in favor of the ball-mill, as a secondary crusher immediately following rock-breakers in series. We commend Mr. Hanson's article to our readers. He is an independent engineer and writes without prejudice. We shall be glad to see the subject discussed in our pages and invite metallurgists or mill-men to state their opinions, as based upon their experience.

METAL prices in relation to the New York Metal Exchange were discussed in our issue of April 29. Apparently the subject is exercising the minds of the trade, for the *Journal of Commerce* and the *Daily Metal Reporter* are advocating the desirability of restoring the Metal Exchange to a position of usefulness, which means rehabilitating public confidence in that institution. By a happy coincidence, a letter was sent on April 29 also to Mr. W. C. Redfield, the Secretary of Commerce, appealing for assistance in overcoming the opposition to recognition of the Exchange. In that letter it is acknowledged that the latter has not served "the true purpose of an exchange, that of ascertaining by bids, offers, and sales the true value of the commodities traded in." [Incidentally, prepositions are poor things to end up a sentence *with*.] The gentleman on the *Metal Reporter* also acknowledges that "for the past eight years, the New York Metal Exchange has been an exchange in name only, due to influences which will be more fully alluded to [prepositions are awkward things] in the following paragraphs." We shall not quote those paragraphs; suffice it to say that our contemporary suggests the sinister enmity of "interests which unfortunately control 75% of the output of American copper mines." We are frank to confess that for once we find ourselves in agreement with those 'interests,' in so far as they refused to recognize a simulacrum. They had one reason for ignoring the so-called Metal Exchange and we have another. But we do agree heartily with the *Metal Reporter*, and the metal producers, brokers, and consumers for whom it speaks, in laying stress on the urgent need for a real exchange where dealings in the metals can be recorded with a view to ascertaining the market-value of them from day to day. It is quite certain that those operating mines—individuals, syndicates, and companies—are suspicious, and rightly so, concerning the devious methods by which prices are now fixed and would welcome the establishment of a clearing-house of quotations. Whether it is worth while to rehabilitate the New York Metal Exchange is another question. It has a habitation and a name; if it can be spring-cleaned and fumigated, it may serve the purpose.

The Rise in Silver

All the metals have risen in price, in most cases rapidly, in consequence of conditions created by the War. Silver was depressed at first. During 1915 the market for the junior precious metal was weak, the bottom being reached on September 4, when the price was 46.25 cents per ounce, the lowest on record. After that it recovered slowly to 56 early in December. Suddenly, toward the end of April the price jumped successively as follows: 64.50, 65.37, 67.00, 67.12, 69.00, 71.37, 73.50.

74.87, reaching the top at 77.25 on May 3. This remarkable change has come as a pleasant surprise to the mining public, despite the intimations made from time to time, in the financial press, that conditions were becoming increasingly favorable to an expansion of demand.

The decline since 1833 is summarized, in decades, as follows:

1833	$1.297	1893	$0.782
1853	1.348	1903	0.534
1873	1.298	1913	0.578
1883	1.110		

The vicissitudes of the market since the beginning of 1914 are outlined thus:

	High		Low		Average,
	Price	Date	Price	Date	cents
1914	59.25	April 28	47.62	Nov. 13	54.8
1915	56.50	Nov. 27	46.25	Sept. 4	49.7
1916	77.25	May 3	55.87	Jan. 3	58.9

The story of silver is interwoven with international economics, changes of money standards, politics, and sentiment ever since 1871. Up to that time, and for two centuries previous, the value-ratio of silver to gold had been maintained at about 16:1, despite the fact that the production-ratio had fluctuated between 4:1 and 50:1. Steadiness of price was due to the free coinage of silver in the chief countries of the world. Until 1871 all the silver that was offered by the miner was taken freely at the average coinage-ratio with gold. In 1871 Germany adopted the gold standard and two years later, in July 1873, commenced to sell its accumulation of silver, thereby forcing France and the rest of the Latin Union to limit their coinage of that metal. Finally, in February 1873, the United States demonetized silver, by reducing the right of legal tender to payments not exceeding five dollars. In 1874, the remaining countries of Europe suspended the mintage of the subsidiary metal except for government account. In 1872 silver was worth $1.322; in 1876 the average price was $1.164. Heavy purchases of silver by the United States Treasury under the Bland Act of 1878 and under the Sherman Act of 1890 delayed a final collapse. That came in 1893 when the Indian mints were closed for the private coinage of rupees. In June of that year the price fell from 81¼ to 62 in one week. A recovery ensued to 76 cents. The repeal of the Sherman Act in October of the same year had less effect than had been expected, but it put a quietus on silver from which it has never quite recovered. On October 31, 1893, the price was 68c. Many of our readers will remember those days: the financial panic; the closing of mines; the reduction of wages; and the hot controversy that brought Mr. William Jennings Bryan into political prominence and caused the late Richard P. Rothwell, editor of the *Engineering & Mining Journal*, to bring forward his clearing-house scheme for regulating the ratio of gold to silver.

The uncovering of enormous bodies of silver ore in the mines on the Comstock lode undoubtedly intimidated the Treasury experts of Europe and the United States in 1873 and 1874, hastening the demonetization of the metal, although it is a fact that the Comstock produced nearly as much gold as silver, in value. In later years, the discoveries at Cobalt and the increasing proportion of silver recovered as a by-product in copper mining had their effect in keeping the price down. The Anaconda Copper Mining Co., for example, produced 9,005,617 ounces of silver last year, while the Butte & Superior obtained 3,563,382 ounces from its zinc and lead concentrates, chiefly the former. Cobalt began to produce in 1905; last year the output was 23,568,147 ounces. During the last three years, however, the troubles in Mexico have crippled production in that important mining region to such an extent that the output of silver has fallen from about 80,000,000 ounces in 1911 to about 35,000,000 last year—no exact figures are available.

Silver has continued to be the basis of international finance between the Far East and London, the latter being the place where the price of silver is fixed. India and China have absorbed an enormous proportion of the silver produced, India alone taking 55% of the world's annual production.

Since the War several new developments have come into operation. China sold silver to Russia and made a big deposit of the metal in London as security for drafts. India made fresh demands, due largely to the requirements of the native troops drawn into the European arena and to Egypt. Indeed, the enhanced use of subsidiary coinage by the troops of the belligerent nations created an effective demand for silver, which was further appreciated by the steady withdrawal of gold when the governments at war began to issue paper money. The uncertainties of warfare caused hoarding of gold, while also creating a demand for hard money in the form of silver coins. Thus silver has, in large part, replaced gold in Europe. The process of substitution continues. It is due to temporary causes, but the effect may continue after the causes have ceased to operate. The outlook for silver is good.

Preparedness for Engineers

Preparation for war has become a real issue among the engineers of San Francisco, if one may judge from the steps being taken to organize the resources of the profession in California for possible war. The officers of the local sections of the five engineering societies—including the American Chemical Society—met recently, on the initiative of a committee of the Civil Engineers, to decide what was to be done. At that meeting, on April 26, it was agreed to call a joint meeting of the five societies for May 2, to receive a presentation of the subject by Army officers invited for the purpose. This general meeting, under the capable chairmanship of Mr. J. D. Galloway, was well attended. Capt. Richard Park explained the methods by which the civilian engineers can prepare themselves to assist the engineer corps of the U. S. Army, in case of war, and Capt. John B. Murphy described the work of the military training camps. These addresses, which were heard with keen interest, were supplemented by a statement from Mr. Allen

H. Babcock on the work of organization for industrial preparedness being done by the Naval Consulting Board. Mr. Babcock, as our readers are aware, is one of the five Californian engineers selected to serve on that Board. At the close of the meeting a short discussion ensued, the consensus of opinion being crystallized in a resolution authorizing the formation of a permanent Conference Committee, to consist of three representatives from each society. It is probable that the first work to be done will be a card index mobilization of engineers, resulting in a record of age, capacity, and experience that will be kept up to date, for use whenever required. Those who are possible military units will endeavor to spend at least one month annually at a military training camp. They will supplement such instruction by systematic study of textbooks on military science. Thus they can acquire some measure of fitness to act as officers of volunteer regiments when the call comes. There are only 4829 officers in the Regular Army, and even after adding all those possessed of some degree of training, at college and otherwise, there are not more than 20,000 men available for duty as officers. A defensive army of only 1,000,000 would require 50,000 officers. The more nearly the youth of the country is prepared by training to do soldierly duty, the less will there be need for a large standing army. More particularly, is it true that the larger the reserve of men capable of acting as officers, the more surely will the country be prepared to prevent invasion. After that, or concomitant with it, comes the mobilization of the industrial resources that supply the munitions and other necessaries of an army in the field. Moreover, even if war be avoided now and in the future, it is quite clear that a systematic inventory of American industries should prove of great help in guiding tariff legislation and in giving information that will be needed nationally in the acute commercial competition that will follow the restoration of peace.

American Youth and Mining

On another page we publish a deeply interesting letter from a mining engineer peculiarly fitted to discuss the subject on which he writes, namely, the rendering of work in mines attractive to the young American. Mr. Albert Burch is a Western man, one who owes his honorable position in the profession of mining engineering to hard work, rare good sense, and that sort of sagacity that is second cousin to genius. When he undertakes to make a suggestion intended to prove helpful to the workers underground, he writes as one having experience and not as a doctrinaire on a platform many feet above his audience. We invite our readers to study carefully what he has written. His plea is presented with the force of sincerity. Starting with a retrospect of conditions in our Western mining centres, he lays emphasis on the fact—to which our own observation over the same period enables us to give intelligent concurrence—that the common labor of the mine, particularly underground, is now done by emigrants from south-eastern Europe instead as formerly by the native sons of the indigenous population—in short, Americans. To give further point to the discussion of this subject, Mr. Burch expresses the belief that during the War, and for some time afterward, there will be a diminution in the volume of immigration to this country from Europe, so that the sentimental phase of the problem will be supplemented by an economic aspect, namely, the lack of the kind of labor that seeks employment underground. Those who operate mines want a steady supply of labor and they want it of suitable quality. To this we would add that unless the signs fail, there is destined to be an intensified exploitation of mineral resources owing to a continually increasing demand for metals, so that the shortage of efficient labor is likely to become more acute during the next decade. What is the remedy for this? Mr. Burch suggests the furnishing of instruction to the American boy while he is working in the mine, so that he may have a chance to perform his work more intelligently and have the further opportunity of equipping himself for promotion. The idea is to aid him in emerging from the dead level of run-of-mine labor and differentiating himself as a skilled worker, serving an apprenticeship for something better—'better' because it affords an avenue of evolution to the use of brain rather than muscle—to the faculties above, rather than below, the chin. Hence the proposal to establish a mining school for the benefit of employees, at the expense of the mining company or of a number of companies operating in the same locality. Now that the 8-hour shift is established, it will be practicable for young workers to devote two or three hours when off-shift to the learning of the elementary principles of science governing the operations in which they take a daily part, such as the breaking of ground, ore-sorting, and timbering. The establishment of such opportunities for instruction should prove no mere philanthropic scheme, but a means of increasing efficiency. While that may not be the primary purpose, it would be a consequence of the basic idea, of rendering mine employment attractive to the sons of the farmer, the storekeeper, and the lesser crafts. Mr. Burch states the case so well that we need not paraphrase his argument. We invite the managers of mines to give serious consideration to the proposal and discuss it in our columns. It appeals to us as eminently reasonable and practicable. We know already what good, both mental and moral—if they may be separated—has been done by the establishment of reading-rooms and places of wholesome recreation for the workers in mines. To put it bluntly, it has repaid the companies handsomely because it has added greatly to the well-being of their employees. This scheme is a little different: it has a separate purpose; but it is only a logical development in a special direction. And apart from the purely industrial point of view, there is that broader phase of a more generous economics that aims to make men happier and more useful to themselves and the community: the enlightened patriotism that aims to develop the American youth into a man of greater capacity and efficiency.

DISCUSSION

Our readers are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment.

The American Boy and the Mine

The Editor:

Sir—When I was beginning my mining career, the Irish and Cornish, with a fair percentage of Americans, swung the hammers and placed the timbers in the mines west of the Rocky Mountains; while American boys, recruited from near-by ranches and country towns, shoveled the 'muck,' pushed the cars, and did much of the surface work about the mines. Even at that time a few miners (and good ones, too) were beginning to arrive from Austria, and timber-men from Finland and Sweden; but the great influx of mine laborers from Southern Europe had not yet reached the Western States.

Today, especially in California, all this is changed. In such old mining centres as Butte, Park City, Tintic, and Grass Valley we find the sons and grandsons of the old-time Irish and Cornish hammersmen running machine-drills in the mines; but, even in these districts, most of the common labor is performed by newly-arrived immigrants from Southern Europe; and in many other Western mines, nearly all underground employees are from the same region. In other words, the American boy as a prospective miner has practically disappeared.

Much has been written since the beginning of the European war regarding its present and future effect upon European emigration; and although all are agreed that while the War lasts emigration will be practically nil, the views of writers as to what will be the condition prevailing after the War are quite divergent. Without taking space in this letter to give the reasons for my belief, I include myself with those who think that for many years American immigration from all parts of Europe will be of much smaller volume than for the years preceding the War. Where then are we to look for the 'mucker' of today who must become the miner of tomorrow, unless American boys can be induced to take up the work, as they did thirty years ago? Furthermore, is it not within the range of possibility that a general improvement in the intelligence of the miners of the future may be brought about by training American boys, instead of European peasants, for the work? I am not among those who subscribe unreservedly to the sentiment that the best qualifications for a 'mucker' are "a strong back and a weak intellect"; and, while not wishing to belittle in any way the hard grinding work performed by immigrants from foreign lands, I believe that most mine foremen will agree that it is easier, on the ground of a better understanding of the language alone, to train a willing and industrious American boy than a raw immigrant. And on the same ground, of the better understanding of spoken orders and printed rules, greater aid is given to safety of operation and the prevention of accidents.

The writer recently visited a mine where underground sorting of ore is necessarily practised, and where, after months of training, the work of the 'muckers' was still unsatisfactory. In part, their failure to do good work was due to lack of knowledge of the language; and in part, I fear, to lack of native intelligence; but, whatever the cause, the mine is losing hundreds of dollars per month because of inefficient sorting.

It has been said that the American boy, as found in the country districts and small towns of California, will not work, and certainly not at such common labor as soils his hands and makes his back ache; and, I fear that, as conditions now exist, this is all too true. But American boys have, in the past, worked as common laborers, and the writer was one of them. But, they will not begin work of that character if they see that it is hopeless for them ever to expect anything better; therefore many such boys and young men are idle, or comparatively idle, today; largely because of lack of opportunity to make a start in some employment that promises future advancement. In the mechanical trades the labor-unions, largely controlled by the foreign element, have so curtailed opportunities for apprenticeship, that it is difficult for a boy to get a start in those lines; and we are today confronted by the spectacle of many American-born boys and young men idling their time away or crowding into poorly paid clerical or mercantile positions, while the more lucrative, if, also more exacting, occupations afford employment to others.

In seeking for a remedy for this situation as applied to the mining industry, we must take into consideration the character and traits of the average American boy who might be made available for mine-work. Such a boy will probably be found more ambitious, though less industrious and more independent, and yet, under proper influences, more tractable than the foreign laborer now employed. He will be more frank in his resentment of unjust treatment, and less suspicious; and therefore will respond more readily to the influence of proper treatment. He will have the ground-work of a common-school education, based upon greater natural intelligence. In physique, he may not equal the imported laborer, though this is a debatable question, but, even

if weaker physically, the difference should be made up in a short time by greater skill. But the chief consideration is, as stated above, that because of his greater ambition, the American boy will not begin work as a common laborer unless he sees the promise of something better in the future, and it is to put before him this promise that the following plan is proposed. I suggest that in each important mining centre the mining company or companies set aside or construct a suitable room or building to be used as a mining-school for the instruction of employees in the theory and practice of mining. The instructor should be a recent graduate from the mining department of the University of California or some similar institution, and in selecting him, care should be exercised to obtain one who has had the maximum of practical experience. The school-hours should not be so long as to be burdensome, but should be so arranged as to afford instruction to men from both the day and night shifts. The instruction should be entirely free to all employees of the interested companies between specified limits of age, and above a specified standard of preliminary education. Just how high this standard should be, need not be discussed here, but no doubt with the aid of the faculty of the State University a two years' course could be devised that would give a man a good insight into the theory of mining, even though at the start he had nothing better than a grammar-school education. The object would be not to give a man a training as a mining engineer, but to fit him in both theory and practice to become a first-class miner, timber-man, shift-boss, or foreman. Having provided the plant and instructor for the school, the next step suggested is for the interested companies to send out an agent, whose duty it would be to select from among applicants in the mining district itself, and from the country adjacent, a few boys ranging in age from 18 to 21 years, who were qualified by physique, intelligence, ambition, and preliminary education to undertake the work of mine-laborers coupled with instruction such as the school could give. They should be given distinctly to understand that their pay would be the same as for other laborers in the same class of employment, and that their jobs could only be held by both doing their work properly in the mine and regular attendance at the school. It is my belief that hundreds of such boys can be found in California, and their proper training will, in a few years, materially raise the standard of the miners employed in the State. The schools would serve the double purpose of supplying instruction and of filling the time of the young men so occupied as to prevent their falling victims to the demoralizing influences that have in the past ruined many American boys in the Western mining camps. Naturally, the majority of those boys taking this training would never advance beyond the grade of expert miner and timber-men, but even this would be a distinct gain both to themselves and to the industry, which would be still further benefited by the better training of the few who might become shift-bosses, foremen, and superintendents. The expense of maintaining such trade-schools, if they may be so called, would not be a great burden upon any mining company, and it is my opinion that it would be much more than off-set within a very few years by the greater efficiency of the employees. Progressive railroad and industrial corporations, for many years, have found it profitable to maintain schools for the better training of certain classes of their employees, and intelligence and skill are quite as valuable to the conduct of mining operations as to most other lines of work. This being true, why not try to devise some plan that will give us more of intelligence and skill? The scheme outlined may not seem entirely practical to those of your readers who control mines; but it is hoped that this letter may lead to a discussion which will result in the general adoption of some plan that will prove practical.

ALBERT BURCH

San Francisco, April 25.

Precipitation of Gold and Silver in Steel Launder

The Editor:

Sir—The following notes relate to leaching with cyanide solutions in the usual way, followed by the roasting of the tailing from a silver ore containing mercury.

The output of the once famous camp of Candelaria used to be milled chiefly at Belleville, Nevada, nine miles distant from the mines. The mills were placed at Belleville on account of water, the supply being piped by a gravity line nine miles long from Marietta Springs. The ore was hauled by wagons. Each wagon with a trailer was loaded with 27 tons. In the later days of Candelaria, a branch of the narrow-gauge railway from Mina (Nevada) to Keeler (California) was extended into the district to bring supplies of wood and mining materials, and to carry ore to the two 20-stamp mills at Belleville. Roasting and pan amalgamation, according to the prevailing method at that time, was the treatment given the Candelaria silver ores. The residue after milling contained 8 oz. silver and from 60c. to $1 in gold per ton.

During the spring of 1914 a leaching plant was erected in the open by a company formed and managed by F. C. Beedle, know as The Belleville Tailing Association. Up to this time the piles of tailing had been sampled by scores of parties, the result being a unanimous decision that they were not workable by cyanidation. The plant was erected despite this opinion; it consists of sixteen 100-ton vats, giving a capacity of 120 tons per day, when the water for sluicing does not have to be used for other purposes. A limited supply is all that is now available.

The low price of silver and the high cost of zinc for precipitation made necessary some change during the season of 1915. Necessity and experience do many new things for ore treatment. It was found that a concentration took place in a small wooden launder that carried the solution from the vats to the storage-tanks at the head of the zinc-boxes. A deposit was made around nail-heads where the mercury formed amalgam and collected

silver and gold. To make real use of this precipitation a launder was constructed out of No. 10 steel sheets, 4 ft. wide by 1 ft. high. A flare of two inches was given to each side, making the top measurement across the launder 4 ft. 4 in. The quantity of solution to pass over this area of precipitation was calculated at from 120 to 150 tons per 24 hours. To give ample scope for the operation a launder 80 ft. long was employed, with a grade of $\frac{1}{8}$-in. per foot. Before using, the launder was given two good coats of carbon paint to protect the steel from the action of the solution. The results for several weeks showed an extraction of 74% of the gold and silver in solution. The remaining metal contents were removed by the zinc-boxes that received the discharge from the wide launder. The zinc 'shorts' from the boxes served to start the precipitation, with some scraps of iron and tin-cans. The mercury forms amalgam on these and continues to gather more, building upon itself. By this system the zinc consumption for this plant was reduced 60%. The advantage in melting the product is also worthy of notice, since a better grade of precipitate is obtained in this way. The mercury dissolved by the cyanide solution is removed by this device. The precipitation of the gold and silver is excellent at all times.

The precipitate is dried with a gentle heat and retorted to recover the quicksilver, and then melted in the regular manner. The cyanide loss per ton of ore leached is $\frac{1}{8}$ pound. The strength of the strong contact is four pounds per ton of solution. The protective alkalinity is carried at $\frac{3}{10}$ pound per ton. A small quantity of lead acetate is all that is needed.

A. G. Harbaugh.

Belleville, Nevada, April 2.

Engineers and Business

The Editor:

Sir—The discussion of the training and status of the engineer has tended to overlook the relation of the engineer to the large organization. The big corporation has undoubtedly come to stay. The tendency of these aggregations of capital and men appears to be continued expansion. Almost all of the great mining and business houses are continually taking over smaller operations and establishing new connections—some of them in foreign countries. In mining, for instance, the Anaconda company, besides constant growth in Montana, is looking for mines in the Andes. In finance, the National City Bank of New York is rapidly securing branches throughout South America and the Orient. Expansion, ramification, and diversity are making American corporations bigger and broader. These new departures and growths are taken care of by the creation of additional departments and by the enhancement of specialization. A need is arising in such departments for technically trained men whose work requires as much knowledge of business and human nature as of engineering. Many of the positions to be filled by these companies can be called semi-technical.

A friend of mine has advanced the interesting idea that the best thing a young engineer can do in order to get on, is to learn something more commercial. What he means is that an engineer who has received the broad foundation of a technical training, which brings clear thinking and the ability to reason from fundamental principles, should pick out a specialty or hobby that will enable him to apply his engineering ideas and his enthusiasm to some lucrative branch of industry. An engineer who remains merely an engineer is likely to become a narrow drudge. More money is to be made and more chance for expression can be found, as a rule, by being half an engineer and half a business-man. One result of the multiplication of departments in the large organizations, and of the present high degree of specialization in industry is a lack of co-operation between departments. This entails much working at cross-purposes, and a good deal of duplicated and wasted effort.

The large businesses, built up so rapidly by combining the abilities of highly specialized workers, do a lot of useless routine because no one has had time to introduce a sense of proportion into their affairs. It has been difficult to get men who could understand two phases of the work at the same time. Many professions and lines of endeavor, we are told, are over-crowded; but the combinations of different abilities necessary for the understanding of particularly complex industries are still rare. One reason for the presence of men of narrow outlook has been the training of technical men who did not have a previous foundation of general education. The future should develop men who are well-balanced combinations of engineers and business-men.

P. B. McDonald.

Berkeley, April 19.

Gold Output for 1915

The Editor:

Sir—In an editorial note in your issue of March 11 you express surprise "that *The Mining Magazine* reproduces the so-called statistics of the world's gold production published at the beginning of the year by the *Engineering and Mining Journal*, the editor in London stating that his own efforts to collect the necessary statistics had proved unsatisfactory to himself." In particular, you instance an error in the *Engineering and Mining Journal's* statistics in connection with the Canadian output, with the inference that we used our contemporary's incorrect figures. As the writer of the editorial in our February issue on the 'Gold Output of the World for 1915,' to which you refer in your paragraph, permit me to say that your remarks give an entirely wrong impression of the nature of the *Magazine's* statistical work, for we used the *Engineering and Mining Journal's* figures only for Mexico, Central and South America, Hungary, and the Dutch East Indies. Our figures for Canada were given correctly, as we used the official returns of the Mines Branch. We had good reason for making estimates that differed substantially

from those of the *Journal* in the case of Madagascar, Congo, Russia, China, and Japan, and naturally, as our article was published six weeks after the *Journal's*, we were able to employ the actual figures of production throughout most of the British Empire. Our editorial fully explained the method of collection of the statistics and analyzed our sources of information, and all should be clear to the careful reader.

I flatter myself that since writing that editorial I have had no reason to regret any individual estimate, and furthermore that the *Magazine's* total agrees remarkably closely with the later figures of the United States Mint. After taking so much trouble in this matter, it is mortifying to have people interpret your paragraph to mean that we had bodily lifted somebody else's incorrect statistics.

EDWARD WALKER,
Assistant Editor of *The Mining Magazine*.

London, April 13.

[Mr. Walker is quite correct in what he says concerning the Canadian figures. The point we raised was that it was absurd for *The Mining Magazine* to quote the New York paper's statistics when it had itself in London all the real figures available, namely, those covering gold mining in the British dominions and the United States. In the first week of January no other statistics were obtainable; we objected to the sham statistics that are now so common at the beginning of each year. To guess three times and to divide by three for accuracy's sake simply gives the similitude of precision to gross inexactitude.—EDITOR.]

Water-Hammer Drills

The Editor:

Sir—Referring to the article on 'Rock-Drilling Practice on the Rand' in your issue of December 11, 1915, it is stated: "Using light water-hammer drills that theoretically can be worked by one native, the predicted drilling speed could not be realized, so that more natives were required than with piston drills."

Where does Mr. Weston get the idea of the piston-machine being simpler to handle than Leyner-Ingersoll water-hammer drills? We are driving a tunnel 8 by 9 ft. for the Burma Mines Co., in Burma, 8770 ft. long, with a 2 by 3-ft. drain, using Chinese Shan labor, and our experience, using both piston and hammer type of machines, has been that the hammer-drills discount the piston-drills in every way, in speed of drilling and speed of changing steel. They are far superior on holes looking up or flat holes and equally as fast on angle-holes. We also found that hollow steel of the same grade stands better than solid, the water helping it to retain an edge.

The Chinese employed here are large and strong, but even at that they were not nearly as fast or efficient on piston as on hammer-drills. We use two coolies on a machine, but often the crank-man will run a hole or more down while his partner is rustling steel or something that will be needed. Three machines are worked on one cross bar. We use a blow pipe to clear the cuttings on all angle-holes. Our best month was January, 1916, when the ground was hard and solid; we made 502 ft. in 29 working days; 27 ft. was the best day's work. One European per shift. We work on four shifts. Let me repeat, in closing, that in comparing piston with hammer-water type drills with native labor, it is all in favor of the hammer drills.

WILLIAM KITTO.

Nam Tu, Burma, March 2.

[The statement to which Mr. Kitto takes exception is quoted from the brief abstract of an article by Mr. E. M. Weston, of Johannesburg, appearing in *The Mining Magazine* last August.—EDITOR.]

Influence of Flotation Oils on Cyanide

The Editor:

Sir—The following tests were made to determine whether any decomposition of cyanide would be caused by any ingredients of the oils used in flotation remaining in the products to be cyanided.

The solution used in all tests contained 0.204% KCN, without alkali. Oils used:

No. 1	Barrett tar
" 2	Barrett tar-oil
" 3	Crude carbolic
" 4	Crude pine-oil, G. L.
" 5	40-40-20 mixture
" 6	Iowa Tiger mixture

No. 5 consists of { 40% El Paso tar; 40% Barrett tar-oil; 20% Carbolic }

No. 6 consists of { 1 part Barrett tar; 3 parts carbolic creosote; 3 parts pine-oil }

The following mixtures were agitated in the proportions shown below, and filtered. The titration of the filtrate shows practically no consumption of cyanide in any case.

Test No.	Solution used, cc.	Oil used, gm.	Final solution after flotation KCN%	CaO
1	400	4	0.198	trace
2	400	5	0.198	trace
3	400	5	0.202	trace
4	200	2	0.202	nil
5	200	2	0.204	nil
6	200	2	0.202	nil

Solution from No. 1 had a slight yellow tinge; from No. 2 and 3, somewhat red. No indications of sulphocyanide were found in these solutions.

No. 4 gave a milky emulsion.

No. 5 and 6 were brownish and somewhat turbid, so that the exact end-point of the titration was doubtful. A portion of No. 5 shaken with excess of lime and refiltered showed KCN 0.196% and CaO 0.098%.

The proportion of oil used in these tests was much in excess of any that would be likely to occur in practice.

J. E. CLENNELL.

Berkeley, March 16.

Fine Grinding: Stamps and Ball-Mills

By Henry Hanson

THE past few years have witnessed many changes in the machinery employed in reducing ore. The stamp, so long dominant in the reduction of precious-metal ores, has gradually been relegated to the position of a primary crusher by reason of the success of the tube-mill; and more recently the use of the stamp as a primary crusher has become questionable, now that the ball-mill, the rolls, and the disc-crusher vie with one another for economic supremacy in reducing a crusher-product to a suitable tube-mill feed.

The tube-mill was first utilized for gold-milling in Australia; the circumstances leading to its success there as a fine grinder may be summarized as follows:

A telluride-sulphide ore did not yield its gold by the ordinary methods of treatment. Experiments with a view to treating the bulk of the lower-grade ores of the Kalgoorlie mines were made, first, by roasting the whole product after crushing, secondly, by wet crushing and concentration, roasting of the concentrate, leaching the sand, and filter-pressing the slime. The results were in no way satisfactory. It was at this time (about 1900) that Dr. Ludwig Diehl, who had modified the Hannan's Brown Hill plant, treating oxidized ore in the district, was induced to turn his attention to the treatment of the sulpho-telluride ores. After a series of experiments he found that by grinding to a fineness not previously attained, the gold could be satisfactorily recovered from the raw ore, using bromo-cyanide as a solvent. The problem then was to find or develop a machine that would economically and satisfactorily reduce the ore to the fineness required. The tube-mill, even at that time extensively used by cement manufacturers, was adopted as a secondary grinder. Other factors that also served to push the stamp aside were the demand for finer grinding that came with the wider application of cyanidation and the introduction of machines for the filtration of slime.

It is now generally conceded that the stamp, if employed at all, should only be used as a primary or intermediate crusher in reducing an ore to a suitable tube-mill feed. This naturally raises the question whether it would not be good economy in some of the large mills, where single-stage reduction is employed, to scrap at least half of the stamps and increase the duty of the remaining stamps by crushing to a size suitable for secondary grinders, that is, follow the stamps by tube-mills. It might be still better to scrap all the stamps and put up a central plant using ball-mills or tube-mills and such primary crushing equipment as would most cheaply reduce the ore from a crusher-product to a tube-mill feed.

A great deal of stress has been laid on the flexible use of stamps, but stamps and tube-mills working together would certainly afford a more elastic arrangement than stamps when working alone, for it is well known that the cost where stamps are employed to crush finer than 6 to 8 mesh is out of all proportion to the work done, and when a product finer than 35-mesh is required the single-stage stamp reduction is no longer considered except where abnormal conditions obtain. In most of the low-grade gold deposits, such as the Homestake, Treadwell, and Mother Lode mines, the single-stage stamp reduction is still in vogue. The reason, apparently, is that a good recovery is made, when crushing to a fineness from 20 to 35 mesh by amalgamation in the mortars and on the plates, the plate-tailing being classified into sand and slime for cyanide treatment or the plate-tailing may go to concentration tables, when cyaniding of the tailing as a whole is economically unprofitable. On the Mother Lode the graphitic nature of the ore has interfered with cyanidation. This fact and the high recovery by amalgamation have checked mill operators in California from going into the problem of fine grinding. On the other hand, much work has been done on the Rand to determine the economic fineness to which an ore can be reduced. The stamps on the Rand are used largely as primary crushers, reducing the ore from a crusher product to a suitable feed for tube-mills, and the tendency of late has been to throw more work on the re-grinding machines. No doubt the practice on the Rand has had considerable influence on the design and practice of some of the latest mills in this country and Canada, for in nearly all new mills of note started within the last few years the stamp has been employed as a primary crusher preparing a suitable feed for a secondary grinder. Amalgamation, if any, has been relegated to the tube-mill circuit. Of the several mills lately started in the Porcupine district none has adopted single-stage stamp-reduction. At the Hollinger the stamps are followed by tube-mills: the crushing is done in cyanide solution and no attempt is made to amalgamate, although early experiments showed that fully 75% of the gold was freed during grinding and was amenable to amalgamation. The Dome mill, in the same district, closely follows Rand practice, stamps followed by tube-mills, and the amalgamation is part of the tube-mill circuit. Two or three of the smaller mills in the Porcupine district use rolls or Hardinge ball-mills, getting away from stamps altogether; but with the exception of the Dome, the aim at all these plants is to make an all-slime product. Just why the stamp should be used so extensively when employed as a primary crusher only is hard to explain. Among the arguments advanced in its favor, are the following: It can be installed in small units; it is flexible; it will operate on any kind of ore; it is fool-proof; and

it is an excellent amalgamating device. In units larger than five stamps, the ball-mill can replace the stamp; and a mill of this type is certainly much more elastic than a stamp-battery as regards the range of grinding. I have never been able to see wherein a stamp is flexible except when working jointly with a re-grinding machine. When a stamp is working alone a certain size of product is required; if you have an over-capacity, it is true, the stamp can be hung up, but this procedure can hardly be called flexibility. The ball-mill should have an equally wide range as to the character of feed that can be taken. As to the argument of fool-proofness, I know of no machine where the personal equation enters more strongly, and where constant vigilance is more necessary than in the operation of stamps: the water and feed adjustments, the height of discharge, the condition of tappets and screens are important details in obtaining the best results. The most legitimate argument in favor of the stamp is its advantage over other machines as an amalgamating device, and it is rather doubtful if this alledged advantage is of great importance today when the plate-tailing goes to concentrating tables or is sent to a cyanide plant for further recovery. If once it can be established that amalgamation does not suffer by being placed in the re-grinding circuit or, at least, that the final tailing-loss is not increased thereby, then the continuance of the stamp to reduce ore from a crusher-product to a suitable fineness for amalgamation (20 to 35 mesh) is, to say the least, doubtful economy.

The arguments against the stamp are higher initial cost, more space, more power, and more water for the work it accomplishes than some of the other machines. The noise is also a feature that places the stamp in a class by itself. These disadvantages may not mean much in small mills, but in large plants they will mean a great deal in the end. The mill-men of California, nevertheless, have been loath to introduce any innovation that tended to lessen the vogue of the stamp and as a result single-stage stamp reduction is the practice, the stamp taking a crusher product and reducing it to 20–35 mesh. It required some courage, therefore on the part of the engineers who are responsible for the Plymouth mill. Here the stamps were pushed back to the position of a primary crusher and the grinding was finished by pebble-mills. The normal capacity of the stamp when reducing a crusher-product to 20–35 mesh is from 3 to 5 tons per day, but when reducing to a size suitable for a tube-mill feed the duty is increased approximately three times.

At the mill of the Alaska Gold, at Juneau, a much more radical departure was made from what was considered standard practice in precious-metal ore-reduction. Here rolls and tube-mills, instead of stamps, were installed and this within hearing distance of the roar of the falling stamps at Treadwell. The rolls, therefore, have supplanted the stamp as a primary grinder in what is, I believe, the largest gold-reduction plant in operation under one roof. This departure from conventional practice has probably done more toward sounding the death knell to any future stamp installation on a large scale than any previous attempt to break away from standard method. Experience at the Utah Copper on the reduction of copper ores had shown that not only would rolls do cheaper work than stamps, but also that only about one-tenth the space was required.

That this method of reduction is more economical both as to initial and operating cost than stamps alone, or than stamps when working jointly with tube-mills and grinding to a like fineness, can no longer be questioned; the only way to explain the presence of stamps in some of the more recent mills is that it is only lately that the merit of some of these newer machines has been established and the tendency among conservative operators has been "to bear the ills we have rather than fly to those we know not of." It is, however, on the base-metal ores that the best work has been done in the development of grinding machinery especially fitted to give the product desired. It is only a short time ago when the practice at Miami was considered the last word in mechanical concentration. The desideratum sought in grinding copper ore precedent to water-concentration was to liberate as much of the mineral from the gangue in as coarse a state as possible. The aim was to avoid slime. Nothing was sent to the grinding circuit that had already been reduced to a suitable fineness. This necessitates stage-crushing and constant removal of the fine; also an elaborate system of classification and subsequent concentration of the different products on suitable tables. The losses were largely in slime, but with the successful application of flotation to chalcocite and other copper sulphide ores the necessity for maintaining the elaborate scheme of classification and concentration, entailing large initial outlays and heavy expense in attendance, was "knocked into a cocked hat." It is therefore quite natural that a great deal of work has been done of late in re-modeling or changing the operating methods of old machines to meet the requirements of new conditions. The aim now is to reduce the ore to the economic fineness, irrespective of the slime made in the operation, at the smallest cost. When fine grinding is necessary the machine that apparently meets this requirement best seems to be of the short tube or ball-mill type. It is generally known that the Marcy mill was chosen to do the work at the Inspiration. This mill takes a crusher-product about 2-inch ring and reduces the ore to 48-mesh, working in closed circuit with a Dorr classifier. A comparison between the work of the Marcy mill when charged with steel balls and the work of the conical or other short cylindrical mills when loaded with pebbles, would be of no particular value. Seven months ago I saw the Marcy mills in service at the Inspiration, and was much impressed by their efficiency. Much more recently I have seen the conical Hardinge mills in operation at Anaconda, both when using pebbles and when using steel balls. Unfortunately, owing to the widely different character of the ore, the feed going to the Hardinge conical mills at Anaconda is so different from that given to the Marcy mills at the

Inspiration that no comparison can be made as to their relative merit when using balls. At Anaconda the copper sulphides only make up a small portion of the total sulphide contained in the ore. Much of the sulphide is removed in as coarse a state as possible; this necessitates stage-crushing, making "the one easy step" reduction out of the question, as the different-size product from each stage of the grinding is sent over suitable jigs or tables for that particular product. The feed to the conical mills is therefore ¼ inch or finer, practically a normal tube-mill feed, but even on this feed it is believed that the capacity of the mills can be greatly increased by using steel balls instead of pebbles. The size of the balls in the various mills used will depend upon the size of the feed and perhaps also upon the hardness of the ore. At Anaconda it was found that 3-inch or smaller balls gave the best efficiency, while on mills taking a crusher product a 5-inch ball is usually employed. The success of the Marcy mills on a crusher-product in single-stage grinding has given a great impetus to other manufacturers of mining machinery to build a mill that will meet the requirements. Owing to the wide difference in the character of the ore in different districts, in many instances necessitating stage-crushing, there is hardly a likelihood of any one machine occupying the field to the exclusion of all other machines. There are, however, strong indications that the scope for mills of the cylindrical type will become much broader than at present and it would not be surprising to see mills of this type in the near future supplant the stamp not only on the American continent but also on the Rand. At any rate our profession will watch the work of the ball-mill with the keenest interest. Only recently an 8-ft. Hardinge mill was put in operation at the Dome. The mill was given 2-inch feed and its work will be practically parallel with that of the Marcy mill. When data are available, a comparison will be of especial interest. Much work has already been done in developing the ball-mill and much more work remains to be done.

Whether single-stage grinding in ball-mills will prove most economical when an all-slime product is desired or even whether the single-stage reduction is economically applicable to any kind of ore will bear further investigation. At any rate it would be hazardous at present to lay down arbitrary rules as to their best application to different ores. It is also quite possible that short tube-mills designed to carry heavy loads of small balls and using liners especially designed for this work will make inroads into the work of the pebble-mills. Ball-mills may be placed in tandem, one mill taking a crusher-product and discharging into a classifier in closed circuit with the second mill, where the fine is removed and the oversize delivered to a mill of proper design, charged with balls suitable for re-grinding.

As regards the question of length and diameter of tube-mills, I might say that in the early experiments at the Inspiration when an 8 by 5-ft. ball-mill was working in open circuit it was found that one of these mills would take an initial feed of 800 tons and reduce 51% of this tonnage to 48-mesh. To reduce the remaining 49% of this tonnage to the required fineness was the problem. Two pebble-mills would do this without materially increasing the power, but the space required for one ball-mill and two pebble-mills was considerably greater than that occupied by two ball-mills alone. At any rate the ball-mill unit was chosen, and it is quite likely that economy in space and simplicity in operation played a more important part in reaching that decision than any advantages in the operating cost.

It will be of especial interest to know what can be done with steel balls in tube-mills. While this has been tried, I do not believe that the trials have been made under the most favorable conditions. It would be necessary to load the mills much heavier with steel balls than with pebbles and as a rule the motors used on tube-mills have no great excess of power. Furthermore, to obtain the best results in tube-mills when using balls, a liner similar to that used to advantage in the different ball-mills would be of decided advantage. The principle involved in grinding in any of the cylindrical mills is the same by impact and by trituration, and any advantage of one mill over another will, I believe, become a question of the liner used and the point of discharge. The speed of mills, the consistence of the feed, and the size of balls used will, of course, also play a part in the efficiency; but these adjustments can be made equally well on all types of cylindrical mills. If a tube-mill of large capacity should be developed using steel balls, it is then quite possible that the preliminary crushing in preparing a tube-mill feed can be done most economically in rolls or in Symons horizontal disc-crushers. It is claimed that these machines will take an ore of 2 to 2½-inch ring and reduce to ¼-in. ring at a cost not to exceed 4 cents per ton when employed in large-scale operations. But unless there is some decided advantage in cost, the single-stage grinding-unit should be preferred on account of its simplicity.

In fine grinding, one of the greatest difficulties is to keep from circulating a large proportion of material already sufficiently fine through the grinding apparatus. The various types of drag-classifiers, when working in closed circuit with cylindrical mills, will carry back to the mill for further grinding from 30 to 40% of material already fine enough. Just how much the grinding efficiency of a mill is reduced by circulating this fine stuff through it, I cannot say. Apparently the only way to make a clean separation is by screening.

Just how far fine grinding may be carried economically is a question to be determined by each mill-engineer for each ore. It would, however, seem that in some cases where very fine grinding is required to liberate the mineral, the fineness of the grinding might be greatly reduced by employing roughing tables of large capacity, returning the roughing product, containing included mineral, from these tables to the re-grinding equipment. This should be especially applicable to gold or silver-bearing sand preceding cyanidation.

Vistas Del Peru

By H. E. West

PERU presents an unprepossessing appearance from the sea. Roadsteads for harbors; sand everywhere: no green thing. A high fog obscures the sky and tempers the tropical sun. That mighty wall, the Cordilleras, parallels the coast. Toward noon the fog lifts and the sharp serrated combs and peaks stand revealed. We dropped anchor off Callao, the seaport of Lima.

Peru produces 64% of the silver of South America. As a producer it ranks sixth among the countries of the world, with 4.2%. The copper production in 1913 was 27,776 metric tons. The city of Lima, population 120,000, was founded by Pizarro, on the banks of the Rimac river in 1535; his remains lie within the cathedral he built, placed there in 1881. Pure Castillano is spoken in Peru. Lima, with its narrow streets and pavements, its overhanging latticed balconies, its many churches with deep-throated bells, breathes an air of sunny languorous Andalusia that still survives and charms. Those familiar with Mexico City instinctively feel a sense of affection for this southern capital. We ascended by the Ferrocaril Central de Peru, the highest railroad in the world, into the heart of the Cordilleras. This railroad was built in the days when Peru was rich and reckless, by that soldier of fortune, Henry Meiggs, of early Californian fame. At Tambaraque is the old smelter, now idle, that in its day made a fortune for its owner, a laborer who subsequently went bankrupt. At Rio Blanco is another smelter, apparently new, but never operated. The mines at Morococha, leased to Backus & Johnston, have been successful, paying off the receivership. These idle smelters at the gate-way of the Cordilleras are eloquent for caution in smelting, if not in mining in this Andean region. At Casapalca, at 13,600 ft. altitude, is an active smelter, whose curdling yellow and white fumes besmirch the clear mountain air. At 15,600 ft. the train has climbed to the roof of the world. From the summit through the *Tunel del paso de Galera* it is 32 miles to Oroya at 3500 ft. lower altitude. From Oroya it is 87 miles across the Junin pampa, where Bolivar whipped the Spaniards in 1824, to Cerro de Paseo, the largest copper-mining centre in Peru, at 14,300 ft. altitude. The Morococha mines, reached by a short branch-line from the summit are mostly controlled by the Cerro de Paseo company, though Backus & Johnston also operate mines in the district. At Casapalca, where are large deposits of copper, the Casapalca smelter produced 79,264 metric tons in 1913, mostly from ores of the vicinity and Morococha. At Huancayo are promising copper deposits and near-by at Antapongo, are lead veins, carrying almost pure galena but low in silver. Railroads are wanting to make this an important mining and smelting centre. The average content of the Cerro de Paseo ore is said to be 4.7% copper; at Morococha the content is higher, averaging 8%; probably a smelter average would be 5%, with silver an ounce per unit. It is generally understood that $20,000,000 was expended by the Cerro de Pasco company before any production was made. The first car of ore was shipped in August 1906. The mines had then been developed for five years. Additional capital has been expended in the development of other mines, as at Morococha. The present output is 800 tons per day. It is claimed that a 400-ton smelter at this high altitude has a capacity of only 250 tons, but by increasing the air-pressure at the blast-furnaces, smelting is improved. Cerro de Paseo is reputed to have the worst climate of any mining-camp on earth. Snow, hail, sleet, or rain is possible on any day in the year, and all may come during the same day. Thunder-storms resemble a combination of shrapnel and high-explosive shells.

Lack of transportation prohibits the development of many promising districts, not quite rich enough to stand the present excessive freight-charges. Llamas are serviceable for light service, but for any considerable tonnage rail-transport is essential. At 16,000 ft. near Arequipa are the celebrated silver mines of Calloma, from which the ancients extracted more silver, it is said, than from the famous hill of Potosi. The company has been reconstructed now for the third time, and several million dollars has been expended. A report by an English engineer states that the San Cristobal vein averages from 6 to 10 metres wide. The matrix is quartz and rhodonite. The silver in the ore, of which 150,000 tons is in reserve, occurs principally as polybasite. The ore is said to average 22 oz. per ton, raised by sorting to 30 oz. The deposits are stated to equal, if not surpass, those of Pachuca. The treatment proposed is to smelt the rich ore to a lead matte, and to concentrate and cyanide the remainder, extracting 85% of the silver and 90% of the gold at a cost of $2.50 per ton on a basis of 3000 tons per month. The anticipated profit is $5 per ton. Former treatment was by pan-amalgamation, roasting, and lixiviation with hyposulphite. The Carahuacra mine has a vein said to be 60 metres wide, containing zinc 25 to 30%, silver 20 oz., gold 0.02 oz. per ton. The mine is situated at Yauli near the railroad. It is under option to Beer, Sondheimer & Company.

The Salpo vein near Trujillo is noted for its rich gold and silver ores, several fortunes having been extracted from near its surface. The vein can be traced for 40 miles, and has been extensively worked. Small shipments are made on north-bound steamers. From reliable authority it is stated that 6 oz. of gold is necessary to

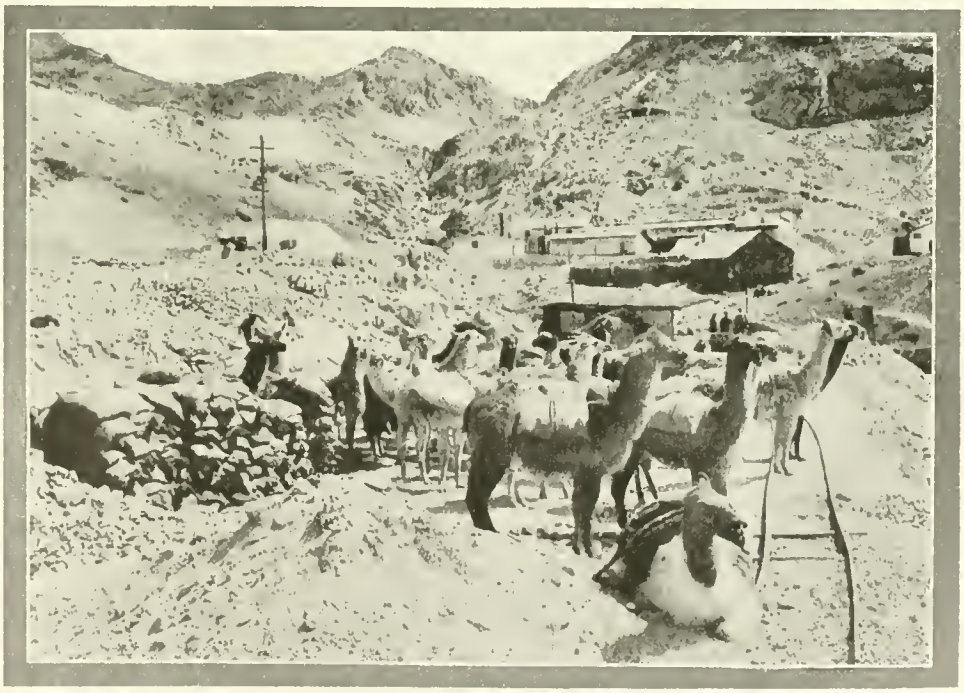
pay freight and treatment charges. The property is 42 miles from Trujillo, with rail part way and 30 miles by mules. By local treatment $30 is required to pay expense. Surface ore only is adapted for local treatment,

SWINGING BRIDGE OF CERCA DE JACJA, PERU.

the sulphides having to be shipped outside. The main ore-shoot is 1000 ft. long and 20 ft. wide, averaging $26 per ton. Unfortunately the lower adit has not yet disclosed the continuation of such a profitable ore-shoot; although sulphide ore equal to 7 oz. of gold has been encountered in small shoots, but these, it is claimed, will not pay to extract under the present high charges. Examples of shipping ores may be instanced: ore from the Calloma mine averages 300 oz. silver and 30 to 40 dwt. gold; the high-grade proustite ore 50% silver with 30 to 40 oz. gold; the silver-lead ore contains from 500 to 700 oz. silver, 24 to 29% lead, with $3 gold. Precipitates from the hyposulphite process contain 16,000 oz. silver and $170 in gold per ton, with 5 to 7% copper.

Extensive molybdenum deposits exist near Juaja, consisting of a ramification of small veins in quartz. The average content is stated to be 3 to 4%. The mining laws of Peru are well framed. Claims up to 60 pertenencias, or 240 acres, can be denounced. Taxes of $15 per pertenencia per annum cause many claims to be whittled down to small proportions, even one pertenencia. No monuments are erected nor any plat of such denouncements entered at the Recorder's office, so that confusion must result. A survey costs $250. A semi-annual Government publication, '*Padron General de las Minas,*' gives the record of all denouncements, with the registered owners, and the standing of each claim. To the visiting engineer this information being authentic, is valuable.

From Huancayo, one fine morning, with mules and packhorses carrying tent, army cots, blankets, and grub, we started for the hills. All went well until the last quarter-mile, which lay straight up a precipitous cliff, without the semblance of a trail. Traveling 18 miles, on a steep grade at 14,000 ft. altitude was all that man or beast could accomplish. That night we lay on the ground and looked at the

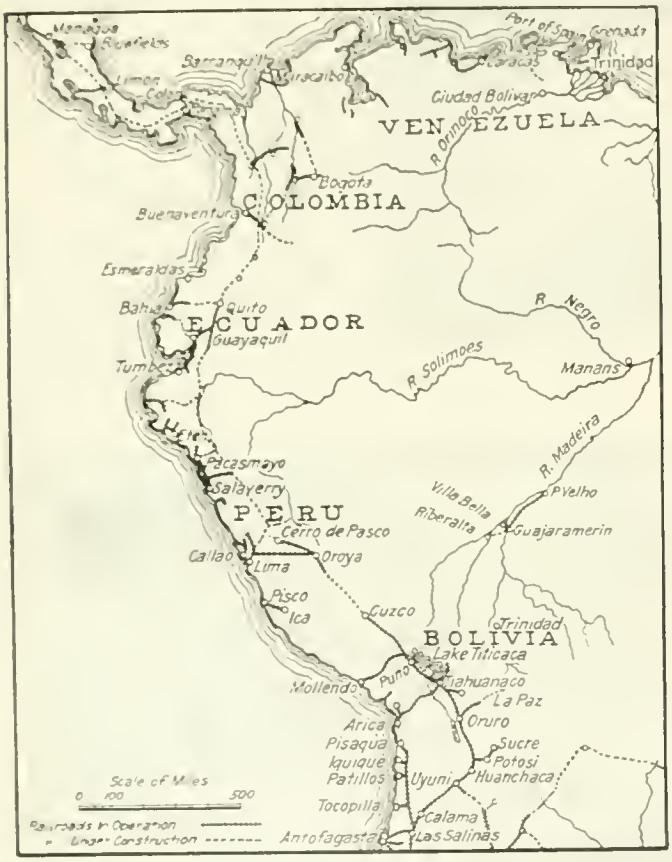


LLAMAS AT THE COPPER MINES OF MOROCOCHA.

stars. To sleep was impossible; to breathe almost as impossible; never did either of us put in such a night. There were minutes when my oxygen supply seemed cut off, and prospects of morning's light grew visionary. The *siroche,* or mountain-sickness, was upon us good and strong. All suffered, even the hardened pros-

peetors, and sometime during the night the camp dog started yelping with the pain and misery. The *siroche* is a malignant sickness, accompanied with fever and general debility; it lasts usually eight days, during which time the sufferer is quite incapacitated.

On the opposite side of the *quebrada* more trials awaited us, steep mountain sides with dry slippery grass. My mule persisted in navigating the outside edge of such delectable trails, but never once did the faithful little animal stumble or trip. In places, however, I preferred to dismount and walk. Once, while descending a wicked trail, one of our pack-horses slipped and started to roll down the steep mountain side, heading for the *quebrada* below. Soon there was another object rolling after the first, which turned out to be the faithful Leonidas. It



PART OF SOUTH AMERICA.

was a funny sight, despite its seriousness, since all our grub was in the pack. Eventually, after several efforts, the animal stayed its tumbling flight in some short scrub, and, strange to say, appeared little the worse for the adventure. It is considered a most discreditable performance to lose a beast on the trail, so all were happy in escaping this indignity, not to mention the financial consequences involved. No fish live in these chilly waters. No beasts roam these grass-covered wastes. No birds float in the thin air, save the *gallinasas*, and, rarely, the great Condor of the Andes. Flowers, stemless with their faces close to the ground, charm the eye. The small star-shaped purple aster, the Shasta daisy, the blue gentian, the yellow dandelion, and the common white daisy —all crouching for protection in the mossy grass. Storms with sleet and wind made the going unpleasant. The deposits visited were irregular bodies in limestone. The ancients had worked them, extracting oxidized ore of 20 to 40 oz. silver per ton. On returning to Huancayo we found a week of *fiesta*, for which time not a soul would leave the town for love or money. Peru was celebrating the 94th anniversary of its freedom. Bunting gaily decorated the one street. The flags of many nations assisted in commemorating July 28, the day of Independence. There were British flags, the Stars and Stripes, Japanese, Italian, Spanish, Turkish, German, Chilean, and Peruvian, not forgetting the five bars of the Republic of China. Truly a respectable showing for a *Cholo* town, high in the Andes. The streets were full of parades. A solemn *misa* was celebrated in the adobe cathedral. Spanish ladies in black mantillas, *señoritas* in white, civic authorities in frock-coats and silk hats, with the brilliant uniforms of the military, formed a charming picture. The last day of the feast was celebrated by a bull-fight. There were six bulls, all from local haciendas. The feast over and our guide reasonably sober, we set forth on what promised to be a hard trip. After examining several properties and passing a chilly night in our tent, we prepared an early start. At midday we had lunch at a sheep-herder's shack. After examining another prospect we returned to Lima.

On August 18 Doctor don José Pardo was inaugurated President of the Republic on the resignation of the provisional president. I was an interested spectator from the window of the Phoenix club. A dense crowd packed the plaza and massed against the palace. The trouble began when stones, supplementing former hisses and jeers, were hurled at the deposed president. Soldiers with bare swords ran amid the crowd and laid about them lustily. A group of officers surrounding the ex-president started shooting. A body of marines fronting the palace joined in and pandemonium broke loose. The crowd fled hotly pursued by the troops with sword and bayonet. Motor-cars and coaches were abandoned. When the shooting started the effect on the occupants of the club was electrical. With united consent all save one or two fell promptly to the floor, face-downward on the carpet. Being, on all occasions, strong on *la costumbre del pais*, I lost no time in following such a lead, expecting the hail of bullets and the shattering glass to start *prontissimo*. Nothing happened. When next I looked forth the ex-president was walking past the corner of the club, in evening dress, attended by a few friends, perturbed but uninjured. A battery lined the street to his home, and soldiers closed all approach. As from the ground sprang Red Cross ambulances for the wounded. The most unfortunate incident was that of Doctor ——, who sallying forth from the palace with the ex-president precisely as the marines joined in the fray, received a bullet in his *cabeza*, putting him out of business.

Next day we sailed from Callao, bearing kindly memories of Peru and the generous hospitality of which we were invariably the recipients, irrespective of creed or race.

Quicksilver Reduction

By Herbert Lang

INTRODUCTION. The metallurgy of quicksilver is simple, consisting in the reduction of a single ore, cinnabar, by means of a single and simple operation, distillation, yielding the metal in a state of almost absolute purity, ready to go into commerce at once. In this respect it can be compared with the means by which metallic—but not pure—gold is recovered from gravel deposits by washing, giving bars that are ready for the market, but are not yet ready for commercial uses; or with those by which the native copper of Lake Superior is won, namely, by crushing and then washing, getting a concentrate which, after a single fusion, produces excellent and salable metal. But mercury is even more simply extracted, and by a process for which seemingly there can never be a substitute. We may also compare its metallurgy with that of the industrial metals, lead, iron, copper, which involves a long series of laborious operations, and the application of concentration, roasting, smelting, refining, and perhaps flotation, before the metal reaches the necessary condition of purity fitting it for use in the arts. Most of the quicksilver of commerce is gained from the sulphide; most of the lead of commerce is gained also from the sulphide; and the same may be said of copper. The metallurgy of all three is practically the metallurgy of their sulphides, and the difference of their metallurgical treatment arises from the different behavior of their respective ores. It is my purpose to trace with some particularity these differences, and observe to what variations in practice they have led. In the opinion of most technical persons, the metallurgy of mercury is in a backward state as compared with that of the others cited; and this is in a certain measure true. They cite as evidence of this presumed condition the dearth of careful and thorough descriptions of processes, the lack of published analyses of quicksilver ores and products, the time-worn nomenclature used by the trade, wherein the output of the furnace is estimated in 'flasks' (a flask contains 75, 76, or 76½ lb., according to the place of production) and especially the want of those accurate accounts of mining geology and operation to which we have become accustomed in connection with the mining and treatment of the other metals. To these we may add the lack of such statistical information, in regard to cost and loss during treatment, as is indispensable when we would go about the task of devising improvements in the art, or suggesting methods borrowed from the later practice in the other branches of metallurgy. The reasons for this backward state lie, I presume, mainly in the simplicity of the reactions upon which the treatment depends, and largely, perhaps, in the economic condition of the trade, which shows little progress during these years in comparison with that of the other metals. The quicksilver market has been held in comparatively few but strong hands of late years, and has suffered much from the lack of such stimulation as enlarged demands produce. A quicksilver 'trust' has been mentioned, and upon it we may lay a good part of the blame for these adverse conditions, since, as we know, the tendency of large producing and trading combinations is inimical to scientific progress.

As before remarked, the extraction of mercury from its ores is effected by a single operation, namely, distillation, by which it is transformed into the elementary condition, converted into vapor, and then, by the abstraction of heat, brought down in the liquid form in which we know it. How this is done and why this particular mode is adopted for the purpose will best appear if we consider briefly the properties of the prevailing mercurial compound, of the materials with which it is most commonly associated, and of the metal itself. The substances with which it is associated in the mine have some bearing on the matter of reduction, but they are not often of a character to interfere, except by adding to the cost of the operation. In no case does the mercury combine with any of the constituents of the ore at the moment of sublimation. The matrix of the ore (cinnabar) consists usually of altered country-rock, such as sandstone, schist, serpentine, with occasionally some minerals of clearly secondary origin, such as vein-quartz, or chalcedony; calcite, dolomite, etc. It is common also to find in the ore some sulphides other than that of mercury; of these the most common is ordinary iron pyrite, a substance somewhat prejudicial to the sublimation process, since its sulphur is expelled by heat and oxygen, and accompanies that of the cinnabar. Calcite and dolomite, both decomposable by the heat at which the ore is worked, are resolved into caustic bases of lime and magnesia, and are detrimental in the sense that much heat is unavoidably expended in their decomposition. I gather from an old print that it was the practice at certain European works, where the ore treated consisted of an evidently pure limestone or calcite containing a little quicksilver, to collect the latter as a by-product in lime-burning—that is, the mercury industry was subsidiary to lime production. This might very well be, as quicksilver furnaces in many cases are purely lime-kilns in form, and work as well on the one substance as on the other. The only essential difference between a kiln devoted to lime-burning and one built for the production of quicksilver consists in the apparatus of condensation necessary for the latter.

It would be perfectly feasible to combine the extraction of mercury with that of many other metals with

which it might be associated, and this is done in several instances. Zinc-blende, for example, being found to contain in certain localities a small amount of mercury, this has been recovered from the fume set free in roasting the blende preparatory to its distillation for zinc. In a broader way one might conceive of mercurial calcite and dolomite as the proper flux for silicious smelting ores, as of copper and lead. Further, as a silicious mercurial ore would flux basic lead and copper compounds, the question broadens itself to include almost any ore of either metal that is found in convenient relation to some other. At one locality in Hungary tetrahedrite containing mercury up to 17% is mined, and the mercury saved, as is the copper. It does not appear, however, that the saving of the former is contingent upon smelting, since the practice is to roast the ore first, oxidizing the metallic compounds, and expelling the quicksilver at once. The interesting question of condensing quicksilver from smelter-fume does not, therefore, receive illustration from this source.

Character of Mercury. Metallic mercury, so striking as being the only metal that is liquid at ordinary temperatures, is in its everyday aspect sufficiently well known, but possesses properties that may escape ordinary observation. Everyone has noted its great weight; it is 13.59 times as heavy as water, and consequently far surpasses silver and even lead in specific gravity. Thus, roughly speaking, a pint of water will weigh a pound, a pint of lead 11½ lb., and a pint of quicksilver 13½ lb. The great density of the latter, taken in connection with its extraordinary mobility, has an important bearing on its metallurgy, as we shall see. The means that have to be employed to prevent its escape through minute cracks and crevices during reduction, and to hold it in transport, render it an exceedingly troublesome material indeed. Mercury freezes into a solid body at 40° below zero, becoming even more dense than before. It boils at about 670°F. above zero, becoming a vapor. In those respects it is similar to water, but possesses a greater range of fluidity; for, whereas water remains liquid through but 180°, mercury remains so for rather more than 700°, another fact of importance in its metallurgy. Its vapor is about seven times as heavy as air, but nevertheless diffuses itself in air and the products of combustion, from which it is difficult wholly to separate it. Mercury loses weight at all times when exposed to the air, and it has been found to give off a little vapor even in great cold. It is said that the frozen metal does so. This propensity renders it impossible to save quite all of the metal by any practicable method of condensation, although the loss from this cause is but small. These considerations must be kept constantly in view, as they have an immediate bearing on the designing of new or the improving of old plants. As an increasing amount of mercurial vapor is given off with increase of temperature, it follows that the metal might all be distilled without raising it to the boiling point of 670°F. This, however, would be a slow process indeed, and applicable only to the liquid metal itself, for where it is held in combination, as cinnabar, which is usual, a considerably higher heat is needed to break up the compound. The absolute amount of heat needed to effect both objects, the decomposition and distillation, is not great. The specific heat of mercury is only 0.033, that is, 1/30 that of water, so that even if it all has to be raised to the boiling point or above, the heat required to do this is comparatively small. While the caloric energy developed by the fuel is great, that taken up in doing actual work on the quicksilver itself forms but a minute part of the whole output of energy. I have computed that in the case of a certain ore with which I am familiar, there is 400 times as much heat required to drive off the water as is needed to decompose and volatilize the mercury it contains. If to this we add the quantity necessary to raise the solid parts of the ore to the temperature of the outgoing gases and vapors, as well as that lost from the furnace by radiation, it will be seen that the useful work of expelling the mercury forms but a very small part of that consumed, probably not more than the thousandth part in this case, which is not far from the ordinary.
